BARK AND AMBROSIA BEETLES OF
SOUTH AMERICA (COLEOPTERA, SCOLYTIDAE)

Stephen L. Wood¹

ABSTRACT

This monographic review of the Scolytidae of South America presents keys and descriptions for the identification of 1339 species, including species in selected genera from Mexico and Central America. **Names rejected** from the South American fauna include (1) *Hylesinus atomarius* Chapuis, a senior name of *Acacaxis abundans* Lea, a species native to Australia; (2) *Scolytodes grandis* (Schedl), a rejected name based on a teratological composite holotype; and (3) *Mimiocurus oleanderi* (Schedl) (*Neodryocoetes*), an African species that was incorrectly named as a European introduction of a Neotropical species. **New replacement names** are presented as *Araptus plaumannianus* Wood (for *Brachydendrus plaumanni* Schedl), *A. praevius* Wood (for *A. frontalis* Wood), *A. nitens* Wood (for *Breviophthorus nitidipennis* Schedl), *A. semisulcatus* Wood (for *Neodryocoetes sulcatus* Nunberg), *Monarthrum amparae* Wood (for *Mimips brasiliensis* Schedl), *Scolytodes schoenmanni* Wood (for *Problechilus glaber* Schedl). **New combinations** are listed for *Acacaxis atomarius* (Chapuis) (from *Hylesinus*, =*Acacaxis abundans* Lea, an Australian species), *Amphicranus incisus* (Schedl) (from *Tricolus*), *A. sexdenticulum* Wood (from *Anchonocerus*), *Araptus brevisetosus* (Eggers) and *A. virtus* (Schedl) (from *Pityophthorus*), *A. celatus* (Schedl), *A. frontalis* (Schedl), *A. granulatus* (Schedl), *A. subsimilis* (Schedl), and *A. sub-sulcatus* (Schedl) (from *Brevipityophthorus*), *Corthyloxiphus aztecis* (Bright), *C. caliginis* (Wood), *C. furvus* (Wood), *C. morulus* (Wood), *C. tardus* (Wood) (from *Corthyocyclon*), *C. emarginatus* (Eggers) (from *Corthylus*), *Corthylus dubiosus* (Schedl) and *C. niger* (Schedl) (from *Metacorthylus*), *C. ustus* (Schedl) (from *Corthyocyclon*), *Cortisinus lobatus* (Eggers) (from *Sternobothrus*), *Gnatholeptus tenellus* (Schedl) (from *Neodryocoetes*), *Gnathotrupes assiduus* (Schedl) and *G. neoadjunctus* (Schedl) (from *Xyleborus*), *Gymnochilus vestitus* Eggers (from *Problechilus*), *Hylocurus longulus* (Nunberg) (from *Micracis*), *Metacorthylus subproprius* (Schedl), *M. subtruncatus* (Schedl), *M. vicinus* (Schedl), *M. truncatorus* (Schedl) (from *Amphicranus*), *M. volvulus* (Eichhoff) (from *Pterocyclon*), *Mimiocurus oleanderi* (Schedl) (an African species, from *Neodryocoetes*), *Monarthrum meuseli* (Reitter) (from *Xyleborus*), *Scolytodes brevis* (Eggers),

S. laevicollis (Eggers), and *S. pilosula* (Eggers) (from *Problechilus*), *S. bruchi* (Hagedorn) (from *Hexacolus*), *Sternobothrus ater* (Schedl), *S. bicostatus* (Schedl), *S. marginicollis* (Eggers), *S. paraguayensis* (Schedl), *S. pilosus* (Eggers), *S. pumilus* (Eggers), *S. transitus* (Schedl), *S. vexator* (Schedl) (from *Cnesinus*), *S. suturalis* (Eggers) (from *Bothrosternus*), *Theoborus crinitulus* (Wood) (from *Xyleborus*), *Tricolus collaris* (Blandford) (from *Amphicranus*), *Xyleborinus longulus* (Schedl) (from *Xyleborus*), *Xylechinus huapiiae* (Schedl) (from *Phthorophloeus*), *Xylechinus nahueliae* (Schedl) (from *Phthorophloeus*). **New alignment of genera in *Ips* and *Orthotomicus***: *Orthotomicus concinnus* (Mannerheim), *O. erosus* (Wollaston), *O. latidens* (LeConte), *O. mexicanus* (Hopkins), *O. orientalis* (Wood & Yin), *O. robustus* (Knotek), *O. spinifer* (Eichhoff) (from *Ips*). **New status** (removed from synonymy) *Phloeoborus nitidicollis* Chapuis [not *P. punctatorugosus* Chapuis], *Araptus caribaeus* (Blackman) [not *A. hymenaeae* Eggers], *A. micrographus* (Schedl) [not a homonym in *Pityophthorus*], *Camptocerus cinctus* Chapuis [not *C. suturalis* (Fabricius)], *Phloeoborus nitidicollis* Chapuis (not *P. punctatorugosus* Chapuis), *P. opacithorax* Schedl [not *P. scaber* Erichson], *P. ovatus* Chapuis [not *P. asper* Erichson], *Phloeotribus rudis* Eichhoff [not *P. setosus* Eichhoff], *Scolytopsis toba* Wichmann [not *S. puncticollis* Blandford], *Xyleborus incertus* Schedl [not a *X. rugosipennis* Schedl subspecies], *X. vitiosus* Schedl [not a synonym of *X. adelographus* Eichhoff], *X. acuminatus* Schedl [not a synonym of *X. grossmanni* Schedl], *Corthylus ater* Schedl [not a synonym of *C. letzneri* Ferrari].

New synonymy of genera includes *Corthylus* (= *Corthyocyclon* Schedl).

New synonymy of species in phylogenetic order includes (**Hylesinini**) *Hylesinus toranio* (Danthione) (= *H. antipodius* Schedl), *Phloeoborus signatus* Strohmeier (= *P. bodei* Eggers, *P. guayanensis* Eggers), *P. grandis* (Erichson) (= *Phloeotrupes punctatus* Schedl), *P. ovatus* Chapuis (= *P. granulatus* Eggers), *P. scaber* Erichson (= *P. lunatulus* Eggers), *P. cristatus* Chapuis (= *P. aspericollis* Strohmeier), (**Tomicini**) *Xylechinus chiliensis* (Nunberg) (= *X. sulcatus* Schedl), (**Diamerini**) *Acacaxis atomarius* (Chapuis) (= *A. abundans* Lea, from Australia),

¹Life Science Museum, Brigham Young University, Provo, Utah 84602

(**Bothrosternini**) *Cnesinus gracilis* Blandford (= *C. laetus* Schedl), *C. nitidus* Eggers (= *C. discretus* Wood), *C. sulcatus* Eggers (= *C. novateutonicus* Schedl), *Pagiocerus luederwaldti* Eggers (= *P. major* Schedl), *Bothrosternus truncatus* Eichhoff (= *B. striatus* Eggers), *Sternobothrus bicaudatus* (Blandford) (= *S. tuberculatus* Eggers), *S. costatus* (Chapuis) (= *Bothrosternus lacordairei* Chapuis), (**Phloeotribini**) *Phloeotribus collaris* Chapuis (= *P. despectus* Schedl), *P. nitidicollis* (Eggers) (= *P. neglectus* Schedl, *P. nebulosus* Wood, *P. levis* Wood), *P. rudis* Eichhoff (= *P. contractus* Chapuis, *P. peruensis* Schedl, *P. lineatus* Eggers, *Phthorophloeus striatus* Eggers), *P. subovatus* Blandford (= *P. argentinae* Blackman), *P. picipennis* Eggers (*P. boliviae* Blackman), *P. transversus* Chapuis (= *P. marginatus* Eggers), *P. setulosus* Eichhoff (= *P. armatus* Blandford), (**Phloeosinini**) *Dendrosinus ater* Eggers (= *D. paraguayensis* Eggers), *Pseudochramesus acuteclavatus* (Hagedorn) (= *Chramesus semibrunneus* Eggers), *P. setifer* Schedl (= *P. abbreviatus* Schedl), *Chramesus globosus* Hagedorn (= *C. eurypeterus* Schedl), *C. spinosus* Brethes (= *C. dentipes* Schedl), (**Scolytini**) *Cenomonyx galeritus* Eichhoff (= *Minulus barbatus* Eggers), *C. panamensis* (Blandford) (= *Loganius setulosus* Eggers, *L. similis* Eggers), *Camptocerus cinctus* Chapuis (= *C. charpentierae* Schedl), *C. costatus* Chapuis (= *C. seriatus* Eggers), *Scolytopsis toba* Wichmann (= *S. argentinensis* Eggers, *Scolytus bruchi* Schedl), *Scolytus carinatus* Chapuis (= *S. atratus* Chapuis), *S. caudatus* Eggers (= *S. conidens* Browne), (**Ctenophorini**) *Pycnarthrum pallidum* (Chapuis) (= *P. reticulatum* Schedl), *Scolytodes gracilis* Schedl (= *S. laevigatus* Wood), *S. guyanensis* Schedl (= *Hexacolus nardus* Schedl), *S. maura* Blandford (= *Prionosceles medius* Eggers, *P. ingae* Blackman), *S. unipunctata* (Blandford) (= *S. cylindricus* Schedl), *S. praeceps* Wood (= *S. tardus* Wood), *S. ater* (Eggers) (= *S. elongatissimus* Wood), *S. opaca* Wood (= *S. opimus* Wood), *S. vicina* (Eggers) (= *Prionosceles dubiosus* Schedl), *S. similis* (Eggers) (= *Prionosceles bolivianus* Eggers, *S. boliviensis* Wood), (**Micracini**) *Pseudothysanoes abbreviatus* Schedl (= *Neoglostatus squamosus* Schedl), *Hylocurus errans* Blandford (= *H. denticollis* Schedl), *H. vianai* Schedl (= *H. intermedius* Schedl), *H. giganteus* (Schedl) (= *H. pseudoimpar* Schedl, *H. interruptus* Schedl), *H. discifer* Eichhoff (= *H. bidentatus* Schedl), *H. retusipennis* Schedl (= *H. dubius* Schedl), (**Ipini**) genus *Orthotomicus* Ferrari (= *Pseudips* Cognato), (**Dryocoetini**) *Dendrocranulus columbianus* Schedl (= *D. limatus* Wood), *D. costalimai* Schedl (= *D. sechii* Schedl), (**Xyleborini**) *Dryocoetoides rusticus* Wood (= *Xyleborus haesitus* Schedl), *D. cristatus* (Fabricius) (= *D. caracicolai* Hopkins), *Xyleborus majusculus* Schedl (= *X. cachoerinhae* Schedl), *X. bolivianus* Eggers (= *X. parvipunctatus* Eggers, *X. rugosipennis* Schedl), *X. incertus* Schedl (= *X. oneratus* Schedl), *Taurodemus flavipes* (Fabricius) (= *Amphicranus perebeae* Ferrari), *Xylosandrus curtulus* (Eichhoff) (= *Anisandrus zimmermanni* Hopkins), *Xyleborinus buscki* Hopkins (= *Xyleborus longulus* Schedl), *X. saxeseni* (Ratzeburg) (= *Xyleborus opimulus* Schedl), *X. gracilis* (Eichhoff) (= *X. schoenherri* Schedl, apparently the male of *gracilis*), (**Cryphalini**) *Neocryphus argentinensis* Nunberg (= *Pacrylus cristatus* Schedl), *Scolytogenes jalapae* (Letzner) (= *Ernoporides knabi* Hopkins), *Hypocryphalus mangiferae* (Stebbing) (= *Cryphalus robustus* Eichhoff), *Cryptocarenus heveae* (Hagedorn) (= *C. acaciae* Schedl), *C. seriatus* Eggers (male may = *Hypothenemus laevigatus* Blandford holotype), *C. punctifrons* Schedl (= *C. brasiliensis* Schedl), *Hypothenemus arecae* (Hornung) (= *Stephenoderes obscurus* Eichhoff, *S. depressus* Eichhoff), *Trischidias atoma* (Hopkins) (= *Ernoporus nigrinus* Schedl), (**Corthylini**, **Pityophthorina**), *Araptus amazonicus* (Eggers) (= *Neodryocoetes sparsepunctatus* Schedl), *A. gracilentus* Schedl (= *Breviophthorus brasiliensis* Schedl, also new homonymy), *A. nudus* (Schedl) (= *Thamnophthorus dubiosus* Schedl), *A. granulatus* Schedl (from *Breviophthorus*), *Spermophthorus apuliae* Costa Lima (= *Conophthocranulus vianai* Schedl), *Pityophthorus terebrans* Schedl (= *P. apicinotatus* Schedl), *P. quadrispinatus* Schedl (= *P. gruneri* Schedl, *P. roppae* Schedl), *P. exsectus* Schedl (= *P. abbreviatus* Schedl), (**Corthylini**, **Corthylinea**), *Gnathotrupes longipennis* (Blanchard) (= *Gnathotrichus castaneus* Schedl), *G. velatus* Schedl (= *G. solidus* Schedl), *G. barbifer* Schedl (= *G. similis* Schedl), *G. fimbriatus* (Schedl) (= *Gnathotrichus frontalis* Schedl), *G. impressus* Schedl (= *G. pauciconcavus* Schedl), *G. nanus* (Eichhoff) (= *Gnathotrichus nanulus* Schedl), *G. consobrinus* (Eichhoff) (= *Gnathotrichus obnixus* Schedl, *Gnathotrichus corthyloides* Schedl, *Gnathotrichus sextuberculatus* Schedl, *Gnathotrichus quadrituberculatus* Schedl, *Gnathotrichus corthyliiformis* Schedl), *Tricolus plaumanni* Schedl (= *Pterocyclonoides octodentatus* Schedl), *Amphicranus gracilis* Eggers (= *Tricolus granulipennis* Schedl), *A. thoracicus* Erichson (= *A. elegans* Eichhoff, *A. retusus* Eichhoff, *A. crenatus* Eichhoff), genus *Monarthrum* Kirsch (= *Xyleborips* Reitter), *M. scrobiceps* (Eichhoff) (= *Eupterxylon comatum* Eggers, *Cosmocorynus latum* Schedl, *C. vagabundus* Schedl), *M. bicolor* (Ferrari) (= *M. sexdentatum* Eggers), *M. laterale* (Eichhoff) (= *Pterocyclon durum* Schedl), *M. fimbriticorne* (Blandford) (= *Pterocyclon obliquum* Schedl), *M. quadridens* (Eichhoff) (= *Anchonocerus brasiliensis* Schedl, *M. eumerum* Schedl), *M. brunneum* (Eichhoff) (= *Corthylus plagiatum* Eichhoff), *M. ingens* (Eichhoff) (= *Anchonocerus excavatus* Eggers), *M. gracilior* (Schedl) (= *Pterocyclon pennatum* Schedl, *P. glabriculum* Schedl), *M. nudum* (Schedl) (= *Pterocyclon appendiculatum* Schedl), *M. obtusum* (Eggers) (= *Pterocyclon quadridentatum* Eggers), *M. minutum* (Schedl) (= *Pterocyclon gibber* Schedl, *P. vernaculum* Schedl, *P. distans* Schedl), *M. laevigatum* (Eichhoff) (= *P. adjunctum* Schedl), *Microcorthylus parvulus* Ferrari (= *M. inermis* Wood), *M. diversus* Wood (= *M. hostilis* Wood), *M. glabratus* Schedl (= *M. pallidus* Schedl), *M. puerulus* Schedl (= *M. castaneus* Schedl, *M. porrectus* Schedl, *M. contractus* Wood), *Corthylus suturalis* Eggers (= *C. obliquus* Schedl), *C. ater* Schedl (= *C. columbianus* Schedl), *C. letzneri* Ferrari (= *C. strigilatus* Eggers), *C. punctatus* Eggers (= *C. nudipennis* Schedl,

C. oliveirai Schedl, *C. neotardus* Schedl, *C. tardulus* Wood), *C. abbreviatus* Eichhoff (= *C. dentatus* Eggers), *C. papulans* Eichhoff (= *C. brunneus* Nunberg), *C. serulatus* Eggers (= *C. argentinensis* Schedl).

Genera New to Science, *Corthyloxiphus* Wood (Corthylini), *Cortisinus* Wood (Phloeosinini).

Species New to Science (phylogenetic order), (**Hylesinini**) *Phloeoborus williei* Wood (Costa Rica), *P. minusculus* Wood (Panama), *P. marahuaci* Wood (Venez.), *P. niger* Wood (Costa Rica), *P. orinocensis* Wood (Venez.), *P. araguensis* Wood (Venez.), (**Tomocini**) *Xylechinus tuberculifer* Wood, *X. squamatilis* Wood, *X. aconcaquensis* Wood, *X. declivis* Wood, *X. solervicensis* Wood (all from Chile), (**Phrixosomini**) *Phrixosoma rubra* Wood (Venez.), (**Bothrosternini**) *Cnesinus pulchellus* Wood (Colombia), *C. excellens* Wood (Colombia), *C. schulzi* Wood (Suriname), *C. squamifer* Wood (Argentina), *C. hispidulosus* Wood (Brazil), *Pagiocerus eggersi* Wood (Brazil), *Bothrosternus rudis* Wood (Brazil), (**Phloeotribini**) *Phloeotribus pilifer* Wood (Peru), *P. hirticulus* Wood (Venez.), *P. schedli* Wood, *P. woytkowskii* Wood (Peru), *P. ebeneus* Wood (Mexico), *P. truncatus* Wood (Colombia), *P. incanus* Wood, (**Phloeosinini**) *Pseudochramesus golbachii* Wood (Paraguay), *Chramesus luteus* Wood (Colombia), *C. argentinae* Wood (Argentina), *C. dentellus* Wood (Ecuador), *Camptocerus annectens* Wood (Brazil), (**Scolytini**) *Scolytus bispinus* Wood (Brazil), *S. plaumanni* Wood (Brazil), *S. excavatus* Wood (Bolivia), *S. canellae* Wood (Brazil), *S. venezuelensis* Wood (Venez.), *S. obscuriceps* Wood (Brazil), (**Ctenophorini**) *Pycnarthrum tuberculiferum* Wood (Ecuador), *P. bahiae* Wood (Brazil), *Scolytodes ageratinae* Wood (Costa Rica), *S. tucumani* Wood (Argentina), *S. peruana* Wood (Peru), *S. gunnerae* Wood (Costa Rica), *S. sparsepilosa* Wood (Argentina), *S. nayaritensis* Wood (Mexico), (**Micracini**) *Pseudothysanoes multispinosus* Wood (Brazil), *Hylocurus flechtmani* Wood (Brazil), *H. plaumanni* Wood (Brazil), *H. colombianus* Wood (Colombia), *H. nodifer* Wood (Colombia), *H. woytkowskii* Wood (Peru), *H. declivis* Wood (Venez.), *H. inequidens* Wood (Brazil), *H. aequalis* Wood (Brazil), *Micracis minimus* Wood (Brazil), *M. tropicus* Wood (Colombia), (**Ipini**) *Acanthotomicus flechtmani* Wood (Brazil), (**Xyleborini**) *Sampsonius ensifer* Wood (Fr. Guyane), *Dryocoetoides versutus* Wood (Ecuador), *Theoborus paurus* Wood (Costa Rica), *Coptoborus nudulus* Wood (Brazil), *C. schulzi* Wood (Suriname), *C. spiculatus* Wood (Suriname), *C. inornatus* Wood (Brazil), *C. carumbensis* Wood (Paraguay), *C. attenuatus* Wood (Brazil), *C. cracens* Wood (Brazil), *C. gracilens* Wood (Brazil), *Ambrosiodmus alexae* Wood (Venez.), *Xyleborus pseudoferox* Wood (Brazil), *X. mimicus* Wood (Peru), *X. araguensis* Wood (Venez.), *X. rugulosipes* Wood (Costa Rica), *X. pseudoacuminatus* Wood (Costa Rica), *X. volutus* Wood (Columbia), *X. caldensis* Wood (Colombia), *Taurodemus colombianus* Wood (Colombia), *Xylosandrus peruanus* Wood (Peru), *Xyleborinus saginatus* Wood (Brazil), (**Cryphalini**) *Stegomerus longipennis* Wood (Brazil), *Acorthylus frontalis* Wood (Argentina), *Cryptocarenus tropicalis* Wood (Venez.), *C. amazonicus* Wood

(Brazil), *C. frontalis* Wood (Venez.), *C. beaveri* Wood (Brazil), *C. barinensis* Wood (Venez.), *Hypothenemus abhorrens* Wood (Brazil), *H. barinensis* Wood (Venez.), *H. meridensis* Wood (Venez.), *H. virolae* Wood (Venez.), *H. rugosipes* Wood (Venez.), *H. parvistriatus* Wood (Florida, USA), *H. ebenus* Wood (Brazil), (**Corthylini**, **Pityophthorina**) *Araptus excavatus* Wood (Mexico), *A. mucunavorus* Wood (Colombia), *A. pernicialis* Wood (Brazil), *A. plicatus* Wood (Venez.), *A. subaciculatus* Wood (Brazil), *A. uruguayensis* Wood (Uruguay), *A. liminarius* Wood (Venez.), *A. kirkendalli* Wood (Costa Rica), *A. guyanensis* Wood (Fr. PREFACE

In past decades, forests and forest products in many areas of the world were considered to be unlimited. As the human population increased from less than 1 billion to more than 6 billion, much of it in the past century, most of the surplus forests of the world were greatly diminished. Measures of conservation once thought unnecessary are now thrust upon us whether or not we like it. The alternative to forest conservation is an enormous population crash infinitely greater than that experienced at Easter Island in prehistoric time when those people eliminated their only source of canoe production and, thereby, their only means of reaching their principal food resource (Diamond 1995). Their population dropped quickly from an estimated 15,000 to about 300 due to starvation or malnutrition.

Bark and ambrosia beetles have been among nature's principal foresters from ancient times until now. Their activities in the recycling of limited forest resources were considered beneficial. In some countries it has been a normal practice to ignore or disregard the loss of half or more of the annual forest production to damage caused by these insects. The effects of insect-transmitted diseases, timber destruction from insect attack in standing forests, either directly killing trees or interfering with seed production, and the devaluation of logs or forest products from devastation must be recognized, reduced, or eliminated in order to more efficiently utilize forest resources. Great progress has been made in these areas in Europe, North America, and several other regions in recent decades. In some other areas, a lack of knowledge and the vastness of the problem have resulted in the diversion of limited financial resources to needs given higher priority, thus, at least partly ignoring the problem. In country after country I have been told "These insects are not a problem here, because they attack only

unthrifty, diseased, and broken trees." Then I walk into their forests and find beetle devaluation and destruction they do not see. The problems are there to those who know where and how to look for them.

It is hoped that this volume will enable others to see the need to recognize the species of bark and ambrosia beetles that occur in or are exported from South America, to investigate their habits, behavior, etc., and to find out exactly what they are doing and why they are doing it in plant species that may ultimately determine our survival.

The compilation of this volume began on 5 December 1995, more than 6 years after my retirement from professional employment, and against my better judgement. However, the need expressed by plant protection colleagues was sufficiently urgent that it was apparent my declining talents were needed. My age was such that I never expected to see this volume completed. Because my time was limited and because curatorial assistance was lacking where some important repository collections occur, my search for the types of several species named early in the previous century could not be borrowed, and my age prevented me from traveling to search for them. While the US Forest Service, USDA (through Dr. Robert Haack) generously provided funds to prepare photographs for illustrations and for publication of the volume, and the M.L. Bean Museum (Brigham Young University) provided space and facilities in which I could work, without research assistants and limited travel funds, progress was slow. With generous advice from the museum staff, the entire volume was entered into the computer by myself. The magnitude of this project was enormous, but the opportunity to engage in this pioneer project has been most rewarding. It is hoped this volume will provide the stimulus for my successors to greatly expand and correct what was accomplished.

INTRODUCTION

This volume was written at the request of an informal consortium of European and Asian plant protection specialists who became alarmed by the apparent unrestricted exportation of raw, largely untreated logs from all South American countries to all parts of the world. Because the literature needed by plant protection specialists, entomologists, and foresters to adequately deal with the insect and disease problems associated with those logs did not exist, I was asked by representatives of that consortium to prepare a volume treating the traditional family Scolytidae (Curculionoidea, Coleoptera) as a first step directed toward the recognition of species that might unintentionally be exported from South America in those logs. The volume requested was to be patterned after the one treating North and Central American Scolytidae (Wood 1982).

In the World Catalog of Scolytidae (Wood & Bright c1992:1–1553) 5812 species are listed worldwide. Literature citations in the catalog indicate that 1126 of those species occur in South America. Virtually all of the citations in that literature refer to the isolated descriptions of species new to science and include little or nothing of the interspecific relationships, distributions, host associations, or economic importance of the species treated.

The purpose of this volume is to list and classify the available Scolytidae of South America in order to (1) clarify the nomenclature of existing nominate South American species of Scolytidae; (2) determine what species occur there; (3) prepare classification and identification keys that will enable workers to determine the species they encounter; (4) assemble existing information on the geographical, ecological, and host distributions for each species treated in so far as existing data permit; and (5) make this information available through publication of a volume designed to aid colleagues in identifying and solving problems associated with the investigation of South American Scolytidae species.

Although 1126 species of Scolytidae have been reported from South America, this region remains one of the most poorly known areas of the earth for this family of insects. Because more than half of the species reported from this vast area are known from a single collection (whether of 1 specimen or many from the same collection or site), I estimate that about one-third of the existing species that occur in South America have been found. If this volume will stimulate others to investigate in greater depth these fascinating and economically important insects and their activities in nature, and apply the new knowledge to the use and protection of our forest resources, the purpose of this volume will be achieved.

While the geographical area of concern here, South America, includes primarily those people who speak and understand either Spanish or Portuguese, the principal users of this volume are expected to reside in North America, Europe, Asia, and Africa. The most nearly universal language employed by scientists from all of those areas is English. For this reason, and because it is the language most familiar to me and the publishers, English was selected for this volume.

Large primaeval tracts of forest land still exist in parts of South America; however, as the human population increases, those areas are being converted to agricultural or urban use, being replaced by large forest plantations of exotic tree species, being exploited by domestic and foreign commercial timber interests, or are gradually coming under planned management. Eventually, most of these forest lands will be under managed care to some degree.

Forests satisfy a multiplicity of needs ranging from the most ethereal esthetic end of the spectrum to the economic realities of tree farming at the other end. They provide the oxygen we breathe, the fuel used by many of us to cook our food or warm our homes; they are a reservoir of food and medicine; they sustain vast populations of birds, mammals, and other animals, including many of us; and they are the source of timber and other products we use and admire. We are not alone on this planet, and we could never survive alone. Each of us must accept the responsibility to protect and perpetuate the ecosystems we share. Bark and ambrosia beetles share some of these same ecosystems and have a place there. An expanded knowledge of what they do and how they fit into world ecology will make this a more enjoyable place to be.

More than a decade has passed since the above paragraphs were written. It seems appropriate to add here a brief statement of the knowledge gained during that decade. The preparation of this manuscript progressed much as was anticipated in treating the Hylesininae and the Scolytinae from Scolytini to the Cryphalini. The groups were based primarily on my collections from Central America, Colombia, and Venezuela, and on the Plaumann and Flechtmann collections from southern Brazil. Excellent series, including both sexes of most species were available for study. As more and more material became available, especially from the equatorial area, problems began to emerge. Most available species from this area were taken either at light or at variously baited or impact traps. Almost none came from adequate series taken from known hosts or accompanied by biological data. An overwhelming number of "species" appeared, each represented by only 1 specimen or by 1 sex. This presented an increasingly difficult

problem in the preparation of identification keys and descriptions. For example, 1 box containing about 50 specimens of *Camptocerus* (Scolytini) was examined and was found to represent about 50 different species, almost none of which were represented in the 20 species in my key to the species of that genus. At that point, the description of species in this (equatorial) area from 1 specimen was discontinued, unless extenuating circumstances (i.e., uniqueness of taxonomic or phylogenetic position, distribution, or host) warranted description. The accumulation of isolated specimens from such collections should not be discouraged, because eventually those specimens will become identified and named. In order to accelerate progress toward that time when this is possible, field workers should make opportunities to collect single-gallery series and series from similar adjacent gallery systems in the same host plant, then correctly date and label those samples. Samples labeled only by a code or field number should be discouraged; they lead to gross errors in geographical distribution or in the identification of that species.

SCOLYTIDAE

The name *Scolytus* Geoffroy (1862:309) was first used for a genus considered worthy of separation from other wood- and bark-boring beetles. This group was raised to Scolytarii Latreille (1807:273), as a subfamily of Curculionidae, then to full family rank, Scolytidae, by Kirby (1837:91–97). The name Scolytidae was employed for this group almost consistently from 1837 to 1995 as a family of Curculionoidea which contained 5812 named species (Wood & Bright c1992). At that time Scolytidae, and several other traditional Curculionoidea family names in Coleoptera were reduced in rank and clustered into 1 enormous family, Curculionidae. This action, prompted by considerations for pure phylogeny, created chaos in the study of the “subfamilies” of Curculionidae, including Scolytidae and Platypodidae. Workers on other submerged “subfamilies” have expressed similar concerns. Because Scolytidae is still used as a family name in the Zoological Record and in the publications of most workers who specialize on this group of Curculionoidea, I have retained the name Scolytidae for use in this volume.

Classification and phylogeny are different disciplines having different objectives. Classification may utilize phylogeny, and phylogeny may utilize elements of classification, but they need not be synonymous. Classification was invented to ease the burden of memory on the human mind as larger groups of things needed to be sorted out and organized into smaller clusters. Classification is employed to make these clusters comprehensible and the individual units identifiable. Phylogeny is focused primarily on genetics and evolutionary descent.

Since about 1988, Curculionoidea specialists have differed radically on the classification and rank of groups within that superfamily. This group is variously estimated to contain in excess of 100,000 named species, more than

60,000 of which are placed in the family Curculionidae. When all existing species are named and cataloged, these numbers could double. This means that approximately 5–10 percent of the existing animal species are or will be placed in 1 superfamily, or 3–6 percent in 1 family. Even though the Scolytidae exhibit anatomical features worthy of separate recognition, such as the occurrence of a single median gular suture connected to a pair of clearly impressed preangular sutures (and supporting internal apodemes), unique tibiae that bear a row of socketed denticles derived from setae, and occupy a unique habitat, they, along with other equally distinct groups, were buried within 1 enormous family, Curculionidae.

In 1998, a world conference of specialists on the classification and behavior of Scolytidae was held at Budejovice in the Czech Republic, as part of the European Congress of Entomology, to discuss current research, new research, and problems faced by the 55 participants. It was unanimously agreed by this group that the overwhelming problem faced by these workers in their research was the burial of references treating Scolytidae literature, about 6000 species, in and among references to more than 60,000 additional species of Curculionidae in the Zoological Record. These workers missed the location of numerous references in the published literature significant to their research. In view of the economic significance of scolytid species, these oversights were associated with enormous losses of research time and potential funding for research. Several of the most dedicated and effective workers said they were changing their research to other fields of study because of this problem. If anatomical characters are insufficient to justify family rank for this group, surely the economic impact these beetles have on society should call attention to a genuine need. Effective research on Scolytidae cannot be done under the present circumstances of needless lost research productivity.

HISTORY

Although several of the species of Scolytidae listed in this volume were named in the eighteenth century (Linnaeus, Fabricius, Panzer, etc.), and hundreds more since then, this is the first attempt to compile a comprehensive taxonomic review of all known South American species of Scolytidae. Previous works included only a few species that were listed or incorporated into taxonomic reviews of mostly exotic genera or tribes that happened to include 1 or more species from South America.

Because of the uniqueness of this project, it was necessary to determine which species of Scolytidae occurred in South America. For this task a review was made of the species listed in the world catalog of Scolytidae (Wood & Bright c1992), where 1126 species were recorded as occurring in South America. To supplement this list, my experience of intensive collecting gained in Mexico (24 months spread over 1953–1968),

Central America (1963–1964, 1966), and in Venezuela (11 months) and Colombia (1.5 months) taught me that (1) many previously unreported species recorded from Mexico and Central America (Wood 1982) also occur in South America; (2) several exotic species have been introduced into both areas; and (3) most of the work reported from South America was done in Argentina, southern Brazil, and Chile. The scolytid fauna from vast areas was entirely unstudied, except for scattered incidental collecting and the publication of brief isolated descriptions of species thought to be new to science. The most significant early collections came from Plauermann (Santa Catarina, Brazil) and Viana (Argentina) that were sent to Schedl. Angelo Moreira da Costa Lima made substantial contributions to our knowledge of Scolytidae from southern Brazil from 1922 to 1967, although his efforts were hampered by his geographical isolation and limited opportunity for travel. Hans Reichardt was a young and enthusiastic worker who made most of his published contributions in Platypodidae, not Scolytidae. He collected extensively and organized scolytid material taken in Brazil, but his life was shortened by an automobile accident while returning from a collecting trip. Most other South American workers focused their primary attention on the study of economic problems resulting from scolytid activity, with little attention on classification or biological activities. The vastness of the South American scolytid fauna, limited resources, and problems with transportation have had a significant effect on the slow progress of the study of these insects in South America. A group of well-educated young investigators in several countries are a welcome recent addition to the labor force needed in South America, and much progress is expected there in the near future.

The publication of a modern reclassification of the subfamilies and tribes of Scolytidae (Wood 1978) and of Platypodidae (Wood 1993), and an invited presentation to the Forest Insect Section of the International Congress of Entomology, Kyoto, Japan, August 1980 (Wood, S.L. *in* Proceedings and abstracts of those meetings), entitled “The correlation of behavior and anatomical characters in Scolytidae (Coleoptera).” These contributions brought renewed worldwide interest in the fundamental traits of scolytids and the potential for predicting phylogenetic relationships that might be useful in solving economic problems associated with Scolytidae. A new higher level of interest, training, and cooperation, coupled with improving worldwide economic conditions and transportation attracted more highly trained workers to conserve, utilize, and protect forest resources worldwide.

BIOLOGICAL ACTIVITIES

Most bark and ambrosia beetle species live only in recently cut, injured, or unthrifty tissues of woody plants that are in the process of dying. Some species occur only in mature fruit or seeds, either before or after they

fall to the ground. Most species complete only 1 generation in this material, then abandon it to search for fresher host tissues in more suitable condition for reproduction. Host tissues must contain sufficient moisture and nutrients for completion of development. Such material usually bears wilted or yellowish green leaves. Older plant material is usually unattractive to the beetles; however, a few species apparently prefer older, drier material. A few species breed in healthy living tissue of vigorous plants and may or may not cause their death. A very few ambrosia beetles attack living trees and complete several generations in 1 plant without killing it. Permanent scars remain in the wood of such trees.

Bark and ambrosia beetles are usually the primary attackers of recently injured or felled woody plants. Some species may complete their entire life cycle (Fig. 1) in as few as 10 days (some *Scolytodes*), or others in 12 months or longer (*Phloeoborus*). A life cycle more commonly requires 20–90 days for completion. Most *Microborus* apparently complete 2 or more generations in bark of the same log without emerging.

In a healthy, undisturbed tropical forest, bark and ambrosia beetles are usually very rare. A small injury to the bark, only a few centimeters wide, can be an avenue for the entry into the host, which in a few generations can kill a large tree. Mass attacks, common to temperate climates, rarely occur in healthy tropical forests. However, such attacks do occur in natural tree falls, logging areas, at construction sites, landslides, etc. It is not uncommon to see a tree, selected for harvest, with scolytids hovering near or boring into it before the tree falls. Decked logs, in the forest or at the mill, commonly have the entire sapwood fully infested within a day or two, unless treated immediately to prevent attacks.

Frequent reference has been made to the terms “bark” and “ambrosia” beetles. This artificial division is based on behavior, not on anatomy or genetics. Bark beetles infest the phloem (inner bark) of their host. In this case, both larvae and adults feed directly on host tissue; they rarely penetrate the wood. Symbiotic fungi are usually, if not always, present but apparently serve in reducing or eliminating host response to the beetle attack. In this case the symbiotic fungi are apparently not a significant food source for these beetles. Each member of the new brood constructs its own individual exit hole for emergence from the bark. Ambrosia beetles are mostly wood-borers, xylomycetophagous, and penetrate rather deeply into the sapwood, much less commonly into the heartwood tissues. The walls of their tunnels are inoculated with fungal spores carried by the beetles which germinate to produce a mycelium, the spores of which are the primary food source of these beetles. It is probable that while all species utilize the mycelium as a food source, most ambrosia beetles are thought to consume a mixture of boring dust (xylem tissue) and mycelium. The brood of ambrosia beetles do not make individual mines (except for partial participation in forming a cradle) and exit their tunnel through the parent entry hole.

Fig. 1. The 4 life stages of *Dendroctonus brevicomis* (LeConte): A, adult; B, eggs; C, larva; D, pupa. (After Keen 1955:3.)

HOST SPECIFICITY

In temperate forests the overwhelming majority of scolytid species are phloeophagous (feed and breed in the inner bark or phloem) or myelophagous (feed and breed in the pith of small stems). There are few xylophagous (wood-boring) species. In tropical forests the reverse is true. There are few phloeophagous and myelophagous species, and the overwhelming majority of species are xylomycetophagous. Although exceptions

exist, many phloeophagous and some myelophagous species are host specific, that is, they feed and breed only in one host species or in a small group of closely related plant species. Xylomycetophagous species are usually polyphagous (each species feeds and breeds in variety of several to many plant species). This principle applies to temperate and tropical areas (Beaver 1979).

It has been observed by me, that host-specific (mono-phagous) species, when the host species is not available during the period of flight, can be capable of surviving for a generation in this biological emergency in another host species. But after doing so, they immediately revert to the normal host when the emergency or stress is removed.

Host Selection and Dispersal

Because most scolytids are able to survive only 1 generation in a given host plant, flight is essential to survival of the species. The original pioneer beetles in their flight (primary attraction) are attracted to volatile substances arising from the injured or dying tissue (Rudinsky 1966). When these substances are in the air, flight is oriented up-wind toward the source. When attractive odors are not detected, the dispersal flight tends to be random.

The objective of the dispersal flight is locating suitable new host tissue in which to live. In certain climates some species seek a host for hibernation or estivation and construct a feeding chamber in which to pass a seasonal period of stress. When warm or moist weather returns, they leave their feeding chambers and resume the search for a host in which reproduction can occur. Most *Dendrocranulus* appear to estivate in forest floor litter during the prolonged tropical dry season. When the rains resume they suddenly reappear in massive numbers.

Once a pioneer beetle finds an appropriate host, it bores into host tissue and begins the release of 1 or more chemical substances (pheromones) that are detected in flight by other members of the species (secondary attraction). By flying up-wind, these beetles are led to the source of the pheromones coming from the pioneer beetles of their species. This mass attraction quickly recruits a population adequate to overcome host resistance and insure the success of species survival.

In the Xyleborini and Coccotyphini pheromones have not been reported. Attraction to new hosts is dependant on host volatiles. In order to ensure reproduction, newly emerged pioneer females, whether previously mated or not, fly to the new host, where they begin a tunnel in the new host.

Galleries

The gallery systems of scolytids are unique and represent the product of a long and complicated evolution. The earliest known fossil galleries were found in the Lower Cretaceous (Brongniart 1877). They appear very

similar to some modern phloeophagous species. The Scolytidae probably first appeared during the Jurassic Period, although the earliest known fossils of adults are from the Upper Cretaceous. From these fossils and from my observations in the field of more than 2000 modern species of Scolytidae, I presume the group descends from small populations of very small curculionoid beetles, which resemble *Protoplatypus* and its allies, in moist tropical forests in broken or diseased trees. The host tissues were probably infested by various fungi that both softened the phloem tissues and enhanced their nutritional value. Initially, the feeding area was probably a protected cavity safe from predators in which the larvae wallowed in previously chewed and digested plant tissue. After some evolutionary time, a cave-tunnel with a definite entrance was formed, to secure the refuge from predators and parasites, that could be blocked by the posterior end of an adult beetle. In the early stages, eggs would have been scattered in the frass within this cave, where larvae and adults could feed. Modern *Trypophloeus* retain this cave-type tunnel for each pair of parents. In 1 modern Mexican *Pityophthorus*, multiple attacking males and females (up to 7 males and 13 females) have been taken from 1 central cave. A more advanced cave tunnel occurs in *Cryphalus*, *Ernoporus*, and *Liparthrum* as a flat, circular (tabular) cave that has egg niches around the peripheral margin, formed by the female parent, into which 1 egg is placed then sealed in by frass by the female parent. In many phloeophagous genera, the nuptial chamber is reduced in size and serves as a mating chamber and staging area for the removal of boring dust. In more advanced groups, feeding tunnels or egg niches are formed. In several myelophagous genera, such as *Sternobothrus*, space allows for only 1 egg gallery and eggs are placed at random in frass and the larvae extend the parent tunnel. In most primitive phloeophagous genera, the eggs are placed at random, and the larvae extend the parent tunnel (some *Scolytodes*). In most advanced phloeophagous genera, the eggs are placed in individual or multiple egg niches (*Orthotomicus*), and the larvae then make individual mines into the phloem.

A typical gallery system (Fig. 2) of a phloeophagous species consists of the following parts:

1. **Entrance hole:** The hole in the outer bark surface that permits entrance into the gallery system.

2. **Entrance tunnel:** The cylindrical tunnel extending inward from the entrance hole. It is usually very short, rarely longer than 1 cm, and usually extends from the bark surface to the cambium area. It serves as an entry into the nuptial chamber and as an area to stabilize and make secure the position of the parent beetle guarding the entrance hole.

3. **Nuptial chamber:** A tabular chamber having length and width dimensions slightly greater than the length of the beetle occupant. It serves as a temporary storage area for frass coming from egg gallery construction, etc., while the male expels this material through the entrance tunnel. It also serves as a turning area for

the beetle to reverse its position during egg gallery construction, oviposition, and nursery care. Copulation usually occurs with 1 or both parents in this chamber or with the female at the entrance of an egg gallery.

4. **Egg gallery:** When 1 or more females are admitted by the male to the nuptial chamber, each female begins to excavate her own egg tunnel. There are rarely more than 5 females in 1 gallery system. Egg tunnels may be either entirely in the phloem, partly in the xylem, or entirely in the xylem. They may be straight or curved, longitudinal, diagonal, or transverse with respect to the grain of the wood of the host plant. The female usually begins to cut egg niches into the sides of the egg gallery soon after her gallery is started. Each niche is large enough to contain 1 egg and adequate to admit the head of the female as she forms it. She will then reverse her position and return to deposit an egg. After again reversing her position she returns to the niche and packs the egg in with frass and oral secretions (beetles have maxillary glands, and do not have salivary glands), then she proceeds to the next niche. The number of eggs in 1 tunnel may vary from none to more than 120. Long egg galleries usually have a series of ventilating tunnels at irregular intervals that extend outward to near the bark surface, or breaking the surface. Whether or not they serve for ventilation, turning areas, oxygen-carbon dioxide exchange, easily opened escape exits, or some other function, has not been determined. In xylophagous and xylomycetophagous genera, this system is variously modified to adapt to the wood-boring habit.

5. **Larval mine:** After hatching, the larvae may (a) enlarge the niche into a cradle large enough to accommodate its adult body, while feeding on fungus mycelium or other products provided to them by the parent beetles; (b) enlarge the parent chamber, usually while feeding communally (in congress) with siblings; or (c) form individual mines. Larval mines may be short, little longer than the larval body (*Pityoborus*), or exceedingly long (some *Scolytus*). Though the egg gallery, nuptial chamber, and entrance tunnel may be kept entirely free of boring dust, larval mines are closely packed with frass (a mixture of boring dust, cast larval skins, excrement, etc.). Larval mines may be entirely in the phloem and not show on peeled bark, or entirely in the wood, but most are in the cambium area and show on the surface of peeled bark.

6. **Pupation chamber:** In most phloeophagous genera the terminal end of the larval mine is expanded slightly and cleared of frass to form a pupation chamber where transformation to the adult stage occurs. It may be formed in the outer bark, in the cambium area, or entirely in the xylem tissue. The new adult may then escape through an individual exit hole immediately after transformation; others may require a maturation feeding period before they emerge. The brood of most phloeophagous and myelophagous species emerge through their own exit hole, although *Pityoborus*, some Cryphalini, and most ambrosia beetles exit through the parent entrance tunnel.

Fig. 2. The common kinds of gallery systems formed by Scolytidae: 1, biramous longitudinal; 2, monoramous longitudinal; 3, stellate, radiate, or multiramous; 4, cave-tunnel (2 postoviposition feeding tunnels are shown); 5, stellate system of *Orthotomicus concinnus* (Mannerheim) showing entrance hole (eh), nuptial chamber (NC), egg gallery (et), egg niche (ep), larval mine (lg); 6, modified stellate; 7, transverse biramous; 8, longitudinal stellate; 9, transverse biramous with larval mines added; 10, modified stellate with nuptial chamber entirely in the bark; 11, ambrosial stellate without cradles (*Xyleborus*); 12, ambrosial cave-tunnel (wood grain runs left to right; in 12 wood grain runs top to bottom); 13, ambrosial stellate with cradles (*Monarthrum*); 14, pith tunnel (*Micracisella*); 15, ambrosia stellate, modified with cradles (poor example of *Gnathotrichus*); 16, 17, 18, ambrosial branching tunnels (*Xyleborus obesus* LeConte). (After Swaine 1918:13.)

Xylophagous, xylomycetophagous, and most spermo-phagous galleries are of the same basic pattern as described above except they are adapted to a 3-dimensional space rather than a 2-dimensional one. In xylomycetophagous species that form larval cradles, the egg niche is enlarged by the larva. In some xylomycetophagous *Corthylus* species, the parents form the complete cradle and inoculate it with mycelial growth before the egg is laid. Groups that do not form egg niches or larval cradles may deposit eggs individually or in clusters in the parent galleries. The larvae may then extend the parent tunnels or feed on the mycelium in branches or chambers formed by the parents (Xyleborini).

Social Behavior

Among those wood-boring Coleoptera in which the adults excavate a tunnel and enter the host to reproduce, the Scolytidae have developed a distinctive social behavior. Most scolytid species infest hosts that are unthrifty, recently injured, or in a somewhat living but declining state. When beetles bore into their tissues, the hosts react by exuding quantities of resin to plug the wound and expel or drown the intruder. Using plant resins, a healthy tree can easily expel or drown a small number of attacking beetles. However, most scolytid species overcome this host resistance through mass attacks on their host plant. For this to be accomplished, an efficient method of quickly recruiting a large population is required. This is accomplished through the release of pheromones (sex attractants) about the time the pioneer attacking beetles reach the cambium area of the host. These volatile substances are formed in the insect body and are expelled with fecal pellets in the frass from the beetle galleries. The odors are carried through the air to both males and females in flight. By flying upwind, the beetles are led to the tree or branch under attack in numbers adequate to overcome the host. Pheromones may attract both males and females of the attacking species, but only a predetermined sex will initiate gallery construction. Members of the appropriate sex will select an area on the bark on which to begin an entrance hole and tunnel. They will vigorously defend that area by butting or dislodging the competitor. The serrations (denticles) on the anterior margin of the pronotum of many scolytids are used for territorial disputes on the bark surface. When the entrance gallery is of sufficient depth and a member of the opposite sex arrives, 1 or both sexes make sounds from stridulating devices (usually near the tips on the inner surface of the elytra or some part of the head), which are used for mate identification in some groups, tactile signals are used in others, and a complex pre-mating dance (Petty 1977) in others. The species-significant signals must be presented to species perfection before the entry-blocking sex will admit the potential mate. Without a fool-proof system of species identification, the reproductive

integrity of the species could not be defended. In outbreeding species the elytral declivity of the pioneer sex (beetle inside and blocking the entry hole) is often modified to receive premating signals from the potential mate. The head and parts of the anterior area of the pronotum may be modified to transmit signals by the potential mate on the outer bark surface. In inbreeders, modifications of the head and declivity rarely occur and are usually minor in magnitude when present.

Four mating systems are recognized in the Scolytidae. These are (1) monogyny, (2) harem (or heterosanguineous) polygyny, (3) inbreeding (or consanguineous) polygyny, and (4) gynogenetic parthenogenesis.

Monogyny is the most common mating system in Scolytidae. It occurs in all Platypodidae (except *Protoplatypus*?); in all Hylesiniinae (except a few Polygraphini and some southeast Asian Phloeosinini); in all Scolytini (except some neotropical *Scolytus*), in all Ctenophorini (except a few *Scolytodes*); in all Scolytoplatypodini, Cactopinini, Crypturgini, Xyloterini; in some phloeophagous Micracini; in many Cryphalini, Dryocoetini, and Corthylini. In monogynous species either sex may initiate the parental gallery, but the habit is consistent within a group. For example, in most *Scolytus* species the female makes the pioneer flight to a new host and begins the initial gallery to produce brood. Those groups in which the female begins pioneer attack tend to evolve toward inbreeding polygyny. Those groups in which the male begins the pioneer attack tend to evolve toward harem polygyny. Regardless of which sex initiates the pioneer attack, the female bores the egg galleries and egg niches. The male guards the entry from within the entrance tunnel and keeps the parent tunnels clear of frass, or leaves immediately after mating. In some *Ceyphalus* copulation occurs on the bark surface before boring begins.

During the dispersal flight, the pioneer attacking sex is exposed to longer periods of predation, storms, and other hazards than are potential mates. For this reason, a higher percentage of the pioneer sex die during dispersal than does the sex of potential mates. To counteract the effect of the disproportionate loss in the attacking sex, the 2 types of polygyny evolved. In harem (heterosanguineous) polygyny, the pioneer male selects a new host tree and bores in and forms an entrance tunnel and nuptial chamber. If the arrival of the female is delayed, he may begin 1 or more egg tunnels. He then guards the entry and admits about 1–5 (rarely up to 19) females to his chambers, then directs his attention toward receiving and expelling boring dust from the entry and blocking the entry with his elytral declivity to prevent the entry of intruders. Mating (copulation) may occur with both sexes in the nuptial chamber, but most commonly the anterior parts of the female are in the opening of an egg gallery and only the male is entirely in the nuptial chamber. Mating may occur repeatedly over several days. The female is responsible for boring the egg galleries, egg niches, and for oviposition and sealing the eggs into

their niche. She pushes the frass (boring dust, fecal material, and other debris) into the nuptial chamber. When the male is absent she may expel frass and block the entry. In some *Scolytus* (*laricis* Blackman, etc.), the male never enters the gallery system; mating occurs at the entrance hole with the female in the entry and the male on the outer surface of the bark. In *Cryphalus* mating may occur with both sexes on the outer bark surface (possibly also in *Hypocryphalus*). Harem polygyny is essentially similar to monogyny except that the male is busier and the available phloem tissues are occupied more quickly.

Inbreeding (consanguineous) polygyny provides a means to quickly remove defective genes from a population and also to stabilize and preserve an effective genotype. Males are haploid, flightless, usually small, rare, and modified; they rarely leave the brood chamber, have a short life span, and are a means to conserve the food resource and species energy to produce more females. The white, unsclerotized male begins mating with female siblings and/or his mother immediately after transformation. I have seen, on several occasions, lone males leave their moisture- and food-deficient brood tunnel and walk up and down their brood-tunnel branch in search of another tunnel containing food and additional mates. They are occasionally successful in their search. Unmated diploid females may leave the brood chamber and fly to a new host tree, where they form a new gallery system. This virgin female may then produce 1 to several haploid eggs, without previously mating, which develop into haploid males. These sons then mate with their mother to produce a brood of diploid females. Thus, a virgin female can quickly establish a new population at a distant locality. Economic control of inbreeding species is difficult. A disproportionate number of scolytid species introduced through commerce to distant areas practice inbreeding polygyny. They are able to establish a viable population from a virgin female (if haplodiploid or a single fertilized female).

Seasonal History

In tropical areas some scolytid species are active and breed throughout the year. Others are active only through the dry or "winter" season and disappear entirely during other seasons (*Dendrocranulus*). Berlese funnel leaf and other forest floor litter samples indicate that such species seek refuge during the wet season in litter where they estivate until favorable conditions return. Spermophagous species may adjust their period of activity to the seasons when acceptable mature seeds of their host plant are available to them. Whether they estivate or find other means of survival has not been determined for these species.

Scolytid populations in tropical areas are confronted by extreme factors of environmental resistance at a level not encountered in temperate climates. Factors such as disease, parasitism, predation, losses due to frequent and

intense rainfall, and others appear to reduce populations of most species to very low levels. Many perpetually rare species appear to be incapable of fully occupying the ecological niche to which they are adapted. For example, a severed woody liana 6–20 mm in diameter and 5 mm in length contained 23 small, very rare scolytid species; the largest representation of any species in this stem was 3 pair. Massive attacks by 1 species, common in temperate forests, are rare in tropical forests.

Life Cycle

The life stages required to complete 1 generation for a scolytid species are as follows (Fig. 1):

Egg: Once the parent gallery is established, eggs are produced by the female. They are smooth, oval in shape, white, translucent, delicate objects, varying in size from one group to another. In some Ctenophorini (*Scolytodes*) an egg may be almost one-third as large as the adult female body; in larger species (*Phloeoborus*) they can be proportionately much smaller. They vary in number in a single gallery system from as few as 3 (some *Corthylus*) to in excess of 100 in *Pycnarthrum*. The number is usually much higher in phloeophagous (bark beetles) than in xylomycetophagous (ambrosia beetles) species. Eggs may be scattered randomly among the frass in the parent gallery or in clusters in clean, rarely used branches of the tunnels. Most species place 1 egg in each niche (*Orthotomicus* may place several in each niche) prepared by the female parent; then it is sealed in by her with a mixture of boring dust and oral secretion. The newly hatched larva usually begins feeding immediately on plant tissue without entering the parent gallery. In some *Corthylus* (*Corthylini*), the parents form complete larval cradles, inoculate them with the ambrosial fungus, then deposit 1 egg in each cradle. Hatching may require as little as 3 days (some *Scolytodes*) or more than 30 days in species living at high altitudes or at other cool climates. Eggs hatch in 7–10 days for most scolytids under normal conditions.

Larva: The larvae are white, C-shaped, legless grubs, with lightly sclerotized, usually brown heads, which usually do not change in form as they grow. The number of larval instars varies from 2 to 5. Lekander (1968) gives the following data based mostly on European species: those said to have 5 instars are *Chaetoptelius*, *Hylurgopinus*, and *Dendroctonus micans* (Kugelann); these figures should be confirmed before 5 instars is accepted for any scolytid species; 4 instars were reported for *D. pseudotsugae* Hopkins, *D. simplex* LeConte, *Hylastes*, *Hylurgops*, and *Tomicus*; 3 instars for *Hylesinus*, *Polygraphus*, all Ipini, *Dryocoetes autographus* (Ratzeburg), and *Xyleborus*; and 2 instars for *Conophthorus*, *Crypturgus*, *Cryphalus*, and *Ernoporus*. The length of the larval period varies from 7 days in some *Scolytodes* to more than 2 years in subarctic *Dendroctonus*. Under ideal conditions larval development usually ranges from about 30 to 90 days. The larvae may feed communally (in congress) while extending the parent chamber

(*Cnesinus*, *Scolytodes*), or they may form individual, separate mines. Larval mines may be as short as the body length of the larva (*Pityoborus*), or long and tortuous (*Phloeoborus*, some *Phloeotribus*). Xyleborini and many *Corthylus* live in tunnels excavated by their parents and, apparently, make no tunnels of their own.

Pupa: The end of the larval mine is usually enlarged slightly and cleared of frass to form a pupal chamber. A few species may bore into the wood [*Scolytus rugulosus* (Muller)] or into the outer bark before forming the pupal cell. The length of the pupal stage may range from 2 days (*Scolytodes*) to more than 30 days, but it usually averages about 6–9 days under ideal conditions. It is rarely selected as the estivation or overwintering stage for any scolytid.

Adult: Following transformation to the adult stage, the beetles may emerge immediately (*Scolytus*), or they may require a period of maturation feeding before emergence (many genera). *Microborus* may not emerge from the host for 2 or more generations. Several species [*Scolytus multistriatus* (Muller)] will emerge from the brood host then fly to a green, living branch where a feeding tunnel is formed. Following a period of maturation feeding, or after hibernation, the beetles then fly to a host suitable for reproduction. It is not uncommon for the parent beetles to emerge, then complete a second, third, or fourth gallery system in the same host tree and produce an equal number of broods. A previously mated female will commonly produce a second brood either with a different male, or without the association of a male, thus giving the false impression that parthenogenesis has occurred. Although most parent adults die in their galleries, occasional individuals survive hibernation or estivation and participate in the production of an additional generation in a second year.

Reproductive cycles: In tropical America, cyclical activity in most species may be correlated with the wet and dry seasons and may be just as conspicuous as in summer and winter in temperate regions. Few comprehensive studies have been made in South America that aid in clarification of this topic.

Ecological Role in a Primary Forest

In temperate areas one of the greatest obstacles to continued growth of a forest is the recycling or removal of dead and dying plant material. In tropical areas the activities of termites, ants, other bark and wood-boring insects, fungi, and other agents of plant decay quickly remove and recycle fallen leaves and other plant material, such that mineral soil lies only a few centimeters below a thin layer of productive soil.

Losses in seed production caused by some *Coccotrypes*, *Scolytodes*, *Hypothenemus*, and isolated examples in several other genera can have a significant impact on native plant reproduction. As commercial tropical fruit and nut production increase, means of reducing losses must be found. Coffee berry-borer [*Hypothenemus hampei* (Ferrari)] damage to coffee production

has had an enormous impact on this crop over most of the 20th century and will continue to do so. Of equal severity is the damage to shrubs and trees in urban areas caused by *Xylosandrus compactus* (Eichhoff). This imported species is capable of killing the most vigorous terminal shoots and fruiting stalks of hundreds of shrub and tree species.

The most conspicuous scolytid damage I have seen in tropical American forests is the infestation of logs in decking areas in the forest and at the mill caused by ambrosia beetles (mostly *Xyleborus* spp., Platypodidae spp.). These xylomycetophagous species infest and stain the sapwood tissues. The logs of some tree species are mostly sapwood and, consequently, are bypassed in logging operations because it is not economically profitable to harvest them and then to lose a significant part or all of the wood to beetle damage. The infesting scolytid species are mostly polyphagous and attack logs from almost all commercially important tree species.

In a healthy standing tropical forest, the bole of most trees is rarely infested by ambrosia beetles. However, a very minor injury that cuts through the bark can attract an infestation that can quickly consume the entire tree. Massive attacks that kill standing trees are almost unknown in endemic South American forests. Such attacks should be anticipated in coniferous plantations when exotic, monophagous pest species are introduced into South America.

Relationships with Fungi

Numerous field observations and many laboratory tests have confirmed the belief that many Scolytidae are associated with mutualistic fungi. The relationships apparently range from the most casual or accidental relationships to intimate mutualistic bonds in which neither fungus nor beetle can survive without the other. In *Phloeoborus* the fungus apparently participates in making the wood more nutritious and easier to bore through. In others (some *Corthylini*) the mycelium, mixed with host tissue, becomes a significant food item. In *Corthylus* and some other *Corthylini*, the fungal spores appear to be the only food utilized. Most ambrosia beetles have developed cavities or pockets (mycetangia/micangia) in which fungal spores are stored and nurtured. The location and form of these structures provide important taxonomic characters for the recognition of some genera and species. They may be located in the oral cavity, at various locations on the prothorax notum, pleuron, or in the coxal cavities, at the base of the scutellum, or the base of the elytra. Mycetangia are described more fully in the publications of Francke-Grossmann (1931–1975), and they are reviewed briefly in Wood (1982:23–25).

Introduced Species

The geographical distributions of animal species are not constant but expand and contract in response to various

natural fluctuations in the environment. In addition, interaction between species may offer unexpected opportunities for range expansion or contraction. For example, human commerce has had a profound effect on the distribution of many Scolytidae (Marchant & Borden 1976, Wood 1982:25–27). The effect of human commerce on North American Scolytidae is summarized by Wood (1977:67–74) and Haack (2006:253–282). An average of about 1–3 breeding populations of exotic scolytid species are introduced to the USA in North America each year. It is expected that similar numbers are introduced to South America each year, but detection is much more difficult due to more diversified and inaccessible vegetation, to more difficult detection, to errors in identification of the species found, and to a limited trained labor force. A list of species introduced into South America reported in this volume is presented in Table 1.

Economic Losses Attributed to Scolytidae

In a primary growth natural forest the Scolytidae perform an important role in the maintenance of vigorous growth and in the early stages of recycling of dead plant tissue. However, their activities come in direct conflict with man when he diverts forest products for use in an economic or cultural system.

The loss of seed production in *Coffea* spp. [*Hypothenemus hampei* (Ferrari)], Brazil nuts [*H. obscurus* (Fabricius)], *Rhizophora* spp. [*Coccotrypes rhizophorae* (Hopkins)], *Podocarpus* spp. (*Araptus impensus* Wood), and in many other species of plants have been enormous. Except for the infamous coffee-berry borer, efforts to control spermophagous species in South America are said by local workers to be primitive or unknown. Although twig borers in forest plantations and in reforestation can be a significant problem for tree species, effective control of pest species had not been developed in trial plots I visited. Losses caused by Scolytidae in standing timber in tropical American forests were considered to be minor in areas visited by me, except where major storms broke trees or where minor injuries penetrated the bark and exposed even the smallest area of xylem. Significant losses of sapwood occurred in the felling of trees and decking of logs in both the forest and at the mill. Because of the high daily precipitation, the use of insecticides was impractical. The immediate removal of logs and sawing them into lumber, followed by kiln drying of the lumber and immediate shredding or burning the waste appeared effective in the areas I visited.

As the value of wood products increase, the need for scolytid pest control to preserve those products will increase. Several countries are experimenting with various methods of control. The exportation of raw unprocessed logs, most of them untreated and with bark on, from South American countries to other parts of the world, most of them untreated and with the bark on, appears to

be a source of disaster, especially for the importing countries. Experience with such importations in the USA appears to have resulted in damage to plantations, orchards, and nurseries that far exceed the value of the imported logs (unconfirmed oral reports).

Natural Control

Scolytid populations in South American forests tend to fluctuate significantly from season to season, from year to year, and from area to area. These fluctuations may be correlated with life cycle, biological opportunity, or other factors inherent in the populations. All organisms have the capacity to reproduce at a rate greater than is needed to perpetuate the race, but overproduction can destroy the pest food supply and severely disrupt the biotic community in which it lives. Among the factors that maintain population balance in the community are large numbers of insect parasites and predators that play a role in the natural control of populations. The published studies of these parasites and predators of South American scolytids are limited and are greatly hampered by the difficulty of identifying the species of scolytids and of their parasites and predators. The information vacuum will be filled as upcoming young workers mature in their professional development. A brief summary of this topic appears in Wood (1982:28–30).

CLASSIFICATION

HISTORY

The earliest scolytid species reported from South America were 14 species named by Fabricius (1801 and earlier), placed mostly in *Bostrichus*. Geoffroy (1762) established the first genus in this group, *Scolytus*, although species endemic to South America were not found in that genus until later. South American species were initially placed in various groups of Coleoptera, such as Bostrichidae (Latreille 1804, Erichson 1836), Curculionites or Curculionidae (Latreille 1807), or the non-Linnean Xylophaga (Ratzeburg 1837, Eichhoff 1864). The first valid family-group name used for these species was *Scolytarii* (Latreille 1807:273), established as a subdivision of Curculionites and based on *Scolytus* Geoffroy. Subsequent authors divided this group into various series of subfamilies and tribes (Hagedorn 1910, Wood 1978, etc.). This volume follows the classification of Wood (1978). At the present time approximately 6000 species of Scolytidae are known worldwide. The species are placed in about 227 genera. About 1339 species are listed here for South America. When all South American species are known, that number is expected to more than double. Obviously, this volume is a very preliminary first attempt to classify the South American scolytid fauna. It is of interest that the total number of previously named species included in this volume is smaller than the 1126 species cited in the literature before this

TABLE 1. Breeding populations of Scolytidae introduced into South America from abroad.

SPECIES	ORIGIN	INTRODUCED TO
<i>Ambrosiodmus rubricollis</i>	SE Asia	Japan, N America
<i>Coccotrypes aciculatus</i>	New Guinea	Panama, Brazil
<i>C. advena</i>	SE Asia, Indonesia	Florida, Brazil
<i>C. carpophagus</i>	Africa	Florida, S America
<i>C. cyperi</i>	SE Asia	Florida, S & C America
<i>C. dactyliperda</i>	Africa	S USA to S. America
<i>C. distinctus</i>	Sri Lanka	Florida to S America
<i>C. palmaris</i>	Africa	S America
<i>C. rhizophorae</i>	Indonesia	Florida to S. America
<i>C. rutschuruensis</i>	Africa	California to S America
<i>Dryocoetes autographus</i>	Europe, Asia	Brazil
<i>Euwallacea fornicatus</i>	SE Asia	Florida, Antilles Isl., S America
<i>E. validus</i>	Japan, E Asia	E USA to Brazil
<i>Hylastes ater</i>	Europe, N Asia	Chile
<i>Hylastinus obscurus</i>	Europe, N Asia	Chile
<i>Hylesinus toranio</i>	Europe, Asia Minor	Argentina, Chile
<i>Hylurgus ligniperda</i>	Europe, N Asia	Argentina, S Brazil, Chile
<i>Hypocryphalus mangiferae</i>	SE Asia, Indonesia	Florida to S America
<i>Hypothenemus africanus</i>	S Africa	S USA to S Brazil
<i>H. areccae</i>	SE Asia	Florida to S America
<i>H. birmanus</i>	SE Asia	Florida to S America
<i>H. fuscicollis</i>	Indonesia	C & S America
<i>H. hampei</i>	Africa	C & S America
<i>H. javanus</i>	Indonesia	Florida to S America
<i>Orthotomicus erosus</i>	Europe, N Asia	Chile
<i>O. laricis</i>	Europe, N Asia	Chile
<i>Premnobius ambitiosus</i>	Africa	(C?) & S America
<i>P. cavipennis</i>	Africa	Florida to S America
<i>P. sexnotatus</i>	(Africa?)	S America
<i>Scolytus kirschi</i>	Europe	S Brazil
<i>S. multistriatus</i>	Europe, N Asia	Argentina
<i>S. rugulosus</i>	Europe	USA to Peru & Argentina
<i>Xyleborinus saxeseni</i>	Europe, N Asia	N & S America
<i>Xylleborus pfeili</i>	Europe	S America
<i>X. similis</i> (established?)	Indonesia	S America
<i>Xylosandrus compactus</i>	SE Asia	Florida to S America
<i>X. morigerus</i>	SE Asia	Mexico to S America

project commenced. This was due to the large number of synonyms found, which greatly exceeded the number of species new to science that were known prior to this volume in the scolytid fauna of South America.

DISCUSSION OF CHARACTERS

A full discussion of characters presented in previous classifications of higher categories in Scolytidae, and their significance, is presented in Wood (1978). A brief summary of that discussion is presented here (Fig. 3A, B, C). Characters of greatest value in determining phylogenetic relationships and the limits of higher categories in the family include the following:

Head: In Curculionidae and the scolytid Hylesininae and primitive Scolytinae (Scolytini, Ctenophorini, Scolytoplatypodini, Carphodicticini), the median posterior portion of the head is essentially truncate (Fig. 4A). In the remaining Scolytinae (Micracini to Xyleborini and Corthylini), the median dorsal occipital area is produced caudad (Fig. 4B), an obvious specialization. The substrate condition of most Hylastini, Hylesinini, Hyorhynchini, and Scolytini may be more closely correlated with habit than with phylogeny. The preular sutures of these groups apparently prevented or altered the development of a true rostrum in Platypodidae and Scolytidae, since the anterior arms of the tentorium are intact, but they are either entirely absent or broken in Curculionidae (Wood 1982:34, 36, Fig. 11).

The eye varies from oval and entire to elongate and entire or emarginate to completely divided [into two separate parts]. While eye shape and position are very useful in the recognition of genera, it should be pointed out that some of the most aberrant eye-shapes occur in some of the most primitive tribes. In general, however, the oval, entire eye is primitive, departures involving elongation or emargination are specializations.

The antennal funicle may have a maximum of seven segments as in other curculionoids. Within Scolytidae the segmentation may be reduced to as few as three segments in the Hylesininae or one in Scolytinae. Reduction in the number of segments from seven is considered as specialization.

The antennal club is formed from three segments. In primitive scolytids, as in many other curculionoids, it is conical (Hylastini, some Hylesinini). Specializations may include compression (flat) or oblique truncation, either with or without the loss of sutures. The club may be symmetrical or asymmetrical, with the sutures equal on both sides or with the sutures on the posterior face strongly displaced toward the apex. In Phloeotribini the intersegmental lines are constricted, thereby forming a sublammellate club with independently movable segments.

Prothorax: The primitive prothorax apparently was short and more or less cylindrical. Specializations include a substantial reduction in the sternal areas accompanied by a change from widely separated to contiguous coxae. A precoxal costa was associated with that change in some primitive groups [Wood 1982:57, Fig. 20]. The dorsal area in specialized groups is declivitous on the anterior area, armed by asperities and much narrower anteriorly. In Diamerini, Bothrosternini (part), Scolytini, and Ctenophorini the lateral margin of the pronotum is costate. This costa appears to be a strengthening device associated with a subconcave pleuron in these comparatively primitive tribes. An analogous raised line in Cryphalini and Corthylini apparently has a different origin and function.

Mesothorax, elytra: While numerous characters of specific and generic interest occur on the mesothorax, items of phylogenetic interest involve the basal margins [of the elytra], interstriae 10, and the mechanism for locking the elytra in [in closed] position when at rest.

In all Hylesininae the basal margin of each elytron is procurved and armed by a series of crenulations. The curvature results from a sutural emargination formed to accommodate the depressed, rounded scutellum. The crenulations are shared by a few species of *Cnemomyx* (Scolytini), but otherwise are restricted to the Hylesininae. A few Diamerini and Bothrosternini have an elevated marginal costa in place of the crenulations. In Scolytinae the elytral bases form a straight transverse line across the body and the scutellum is large, flat, and flush with the [elytral] surface.

Most primitive tribes contain at least some members having interstriae 10 continued to the apex. In more specialized groups striae 9 and 10 converge near the middle of the elytra, thus eliminating the posterior half of interstriae 10.

On the sutural and costal margins of the elytra near the base are grooves that interlock at the suture with the opposite elytron and on the costal margin with the metepisternum. The details of these structures are useful in determining phyletic relationships of major groups.

Metathoracic tergum: In some Hylesininae (Diamerini, Bothrosternini, Phloeotribini, Phloeosinsini, Hypoborini, Polygraphini) the scutellar area of the metanotum fuses with the postnotum, thus eliminating the intersegmental suture. The intersegmental suture is present in the remaining Hylesininae and in all Scolytinae. In addition, the scutoscutellar suture follows a much shorter, more lateral route in those groups with a fused postnotum. These two characters make possible a major division of the Hylesininae.

Metathoracic pleuron: In Curculionidae, primitive Hylesininae, and primitive Scolytinae the pleural suture descends vertically from the pleural wing process to the groove on the episternum that receives the costal groove of the elytra. At that point the pleural suture turns abruptly and follows the groove caudad to near the pleural coxal process. The anterior end of the lower costa that forms the metepisternal groove is higher, often spinelike, and may persist when the remainder of the groove is lost. In the higher Hylesininae and higher Scolytinae the groove is lost, the episternal spine is displaced ventrad, and the pleural suture runs a much more direct route from wing process to coxal process, often quite remote from the position of the costal margin of the elytra [Fig. 5]. In Cryphalini the episternal spine is modified and in Corthylini it is lost and replaced by a small, transverse groove.

Legs: Tibial characters have been used extensively in scolytid classification. The primitive protibial form is thought to be similar to that of *Protohylastes* [Wood 1982, Fig. 35], which has three apical spines (Wood 1973: 77–90). The small mesal spine apparently becomes the apical spine of Scolytidae; the larger, middle spine becomes the apical spine of Platypodidae and the major lateral spine of Scolytini; and the smaller lateral spine in all other groups. The major lateral spine, and some supernumerary denticles, are not socketed [Fig. 6]. All of these lateral spines are replaced by socketed teeth (Wood 1982, Fig. 34), presumed to be of setal origin, in all higher groups (Wood 1978).

In several of the more primitive groups tarsal segment 3 is broad or bilobed. In Diamerini (part), Xyleborini (part), and Xyloctonini the tarsal characters are of some value in classifying genera of these tribes.

Abdomen: In Carphodicticini, Ipinini, Dryocoetini, Xyleborini, and all Platypodidae female abdominal segment 8 is visible, pubescent, and almost as large as in the male. In all other scolytids and most curculionids it is of reduced size, lacks pubescence, and is telescoped beneath and hidden by tergum 7 (Fig. 7).

In Hylastini, many Hylesinini, and Phloeotribini the posterior margin of male tergum 7 bears a median, bituberculate, stridulatory device that scrapes against the adjacent inner surface of the elytra. The value of this

INTRODUCTION

character is uncertain, it is not always present in groups that normally possess it. It may be significant that a comparable character occurs in most Platypodidae (Wood 1982:39–41).

Phylogeny

The Scolytidae and Platypodidae apparently arose as a monophyletic unit from the segment of the

Curculionoidea having one gular suture before preular sutures were lost in the remainder of the phyletic line that gave rise to the Brentidae, Attelabidae, Apionidae, and Curculionidae, but well after the groups having two gular sutures, or remnants of them (Belidae, Nemomychidae, Anthribidae) had branched from the main stem of evolutionary development. Long after the basic scolytid-platypodid characters and habits had been fixed, this evolutionary line radiated into three groups

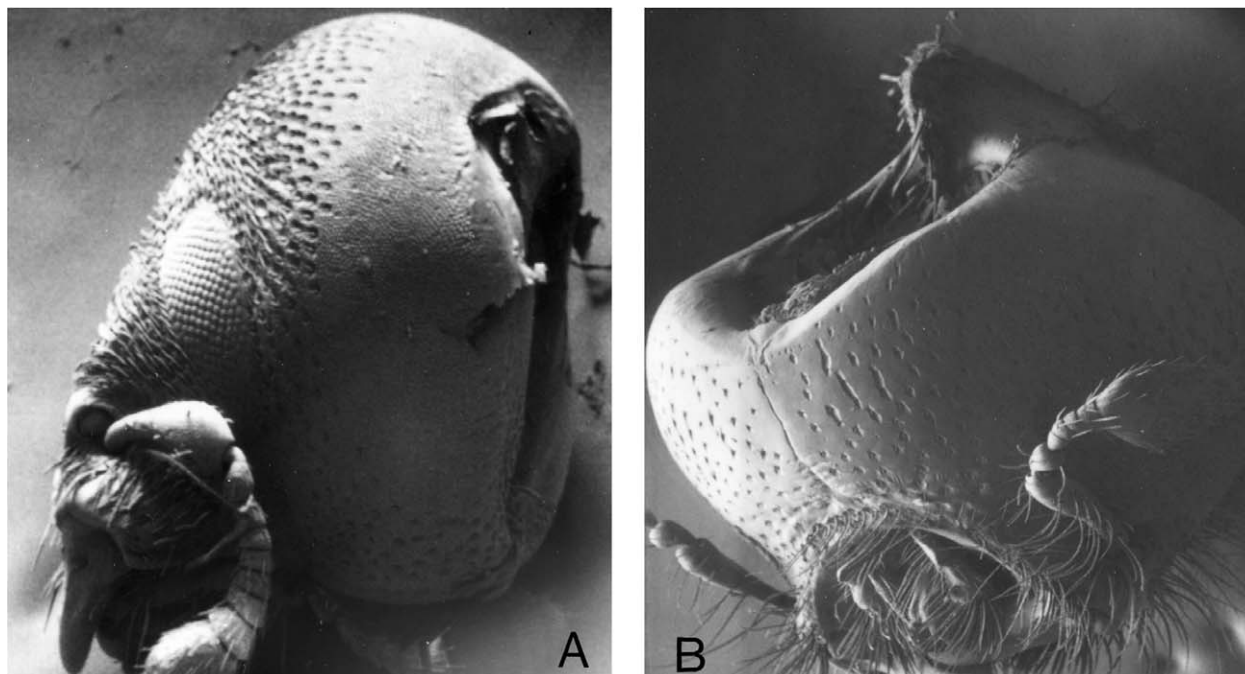

Fig. 4. A, *Hylastes nigrinus* (Mannerheim), lateral aspect of head; note antenna, and undeveloped dorsal occipital area (Left side near middle of foramen magnum damaged in preparation). B, *Ips woodi* Thatcher, ventrolateral aspect of head; note post-gula, gular suture, pregula, and extended dorsal occipital area. (After Wood 1978.)

at approximately the same geological time (possibly late Triassic to early Cretaceous). These three groups presently include representatives among their primitive tribes having (1) a 7-segmented antennal funicle, (2) a fully formed pubescent female tergum 8 basically similar to that of the male, (3) basically similar tibiae that lack socketed supernumerary spines on the lateral margins, (4) a fully developed interstriae 10, (5) the same general body habitus, and (6) the phloeophagous habit. The evidence is inconclusive as to which of these three groups branched from the main scolytoid evolutionary stem first; however, because of the somewhat larger number of primitive characters and the different appearance (probably based as much on distinctive habits as on genetics), coupled with unique specializations, the Platypodidae are regarded by me as the most primitive. For similar reasons the Hylesininae are considered to be more primitive than the Scolytinae. The Scolytinae are considered to represent the main line of scolytid evolution. The accompanying dendrogram [Wood 1982:43, presented here as Fig. 8] illustrates possible phylogenetic relationships of major groups within these families.

The most primitive known representative having hylesinine characters is *Protohylastes*. It could equally well be placed as the most primitive representative of the Platypodidae (Coptonotinae). It shares many characters with *Coptonotus*. Except for the antennal club and tibiae, it could be placed in the Hylastini with complete confidence. It is placed as an aberrant genus of

Coptonotini until more is learned about its structure and habits.

Platypodidae: The pregular sutures, numerous other structural details, and the shared ecological niche suggest a close relationship to the Scolytidae. The 7-segmented funicle (*Protohylastes* and *Coptonotus*), strongly procurved antennal sutures (*Coptonotus*), fully developed female abdominal tergum 8, complete interstriae 10, route followed by the scutoscuteellar suture, route followed by the metapleural suture, tibial characters, elytral locking mechanism, the polygynous habit in *Protoplatypus*, and other characters indicate a closer, but very primitive connection to Scolytinae rather than to Hylesininae. The closest affinity of Platypodidae (through *Protohylastes*) to Hylesininae appears to be through *Diameris* (Diamerini), which possesses several very specialized features. The closest affinity (through *Protoplatypus*) to Scolytinae appears to be through *Cnemonyx* (Scolytini), *Scolytodes* (Ctenophorini), Carphodicticini, and Scolytoplatypodini.

Hylesininae: The fusion of the metanotum to its postnotum [Fig. 5] apparently took place very early in hylesinine evolution as evidenced by the occurrence of tibiae without socketed teeth in both divisions (Hyorrhynchini, Diamerini, and Phloeotribini). More primitive characters, with fewer specialized ones, appear to be associated with Hylastini, Hylesinini, and Tomicini (listed in increasing order of specialization), with the Phrixosomini and Hyorrhynchini representing specialized relicts of otherwise primitive groups.

Fig. 5. Diagrams of Scolytidae metanota; 41, *Chramesus hickoriae* LeConte, dorsal aspect (arrow points to remnant of intersegmental suture); 42, same, pleuron (arrow at metepisternal spine); 43, *Hylastes nigrinus* (Mannerheim) dorsal aspect, with labels indicating intersegmental suture (is), postnotum (pn), scutellar groove (sg), and scutoscutellar suture (ss); 44, same, lateral aspect, with labels at metepimeron (mn), metepisternum (ms), pleural suture (ps), and metepisternal spine (s, marked by arrow); 45, *Cnemonyx panamensis* (Blandford), dorsal aspect (arrow points to intersegmental suture); 46, same, lateral aspect (arrow points to metepisternal spine); 47, *Pityophthorus crotonis* Wood, lateral aspect (arrow points to metepisternal groove that has replaced the spine of other tribes). (After Wood 1978).

In the more specialized hylesinine line are found the more primitive tibiae (*Diamerus*, *Aricerus*), pronotum (*Diamerus*), elytral bases (Bothrosternini, *Diamerus*), and other characters, but they also exhibit the greatest specializations (reduced funicular segmentation, aberrant antennal club with loss of sutures, etc.). The fusion of the postnotum obviously took place very early in hylesinine evolution, as evidenced in that group by the much greater structural and biological diversity. The Diamerini and Bothrosternini, which appear to be geographical replacements of one another, share the greatest number of primitive features; they also appear to have diverged further than the other groups from the original ancestral

line. The Phloeotribini also diverged rather early as evidenced by the protibia of *Aricerus* and by the very different, sublamellate, antennal club. The Hypoborini and Polygraphini appear to be specializations that diverged rather recently from the Phloeosinini.

The basic structural relationship of most Scolytinae to Platypodidae is closer than to Hylesininae, although the biological affinity is closer to most Hylesininae. The strongly procurved antennal sutures of *Coptonotus* (and the obscure lines that suggest obsolete sutures in other Coptonotinae and a few Platypodidae) is a common character in Scolytinae (Scolytini, Ctenophorini, Micracini, Xyloctonini), but occurs only in Diamerini (*Diamerus*)

Fig. 6. Apex of prothoracic tibia of *Polygraphus rufipennis* (Kirby) showing socketed denticles at margin. (After Wood 1978.)

and Bothrosternini (*Pagiocerus*, *Eupagiocerus*) in the Hylesiniinae. The Scolytini apparently diverged very early from the main evolutionary line in Scolytinae, as evidenced by antennal, tibial, metapleural, and other characters. The divergence of Scolytoplatypodini and Ctenophthorini soon followed, as evidenced by a significant change in tibial characters, and these geographical replacements then diverged from one another. . . . [The Scolytini replace socketed lateral tibial spines with an unsocketed apical spine. Jordal (1998:95) demonstrated that socketed spines were lost in some of the Ctenophorini and that Scolytini apparently diverged from them]. Except for the socketed tibial teeth, Carphodicticini most nearly resemble my concept of a primitive platypodid in antennal, frontal, pronotal, coxal, metapleural, metatergal, and abdominal characters. However, the tibiae, and other characters, place it more nearly intermediate between *Protoplatypus* and Dryocoetini. The Crypturgini, Dryocoetini, Ipini, Xyloterini, and Xyleborini represent a unit of closely related tribes. Micracini and Cactopinini appear somewhat related, as do Xylotonini and Cryphalini. The relationship of Cortlylini to other tribes is not clear; they exhibit some very primitive features as well as many of the most specialized ones in the family (Wood 1982:41–44).

Biogeography

During much of the geological history since the Tertiary, South America was an island. Prior to that, about late Cretaceous or early Tertiary, South America was connected to western Africa. Supporting evidence of this connection comes from the genus *Phrixosoma* (Phrixosomini), a compact genus (in America) confined to Guttiferae hosts, where 9 species occur in tropical

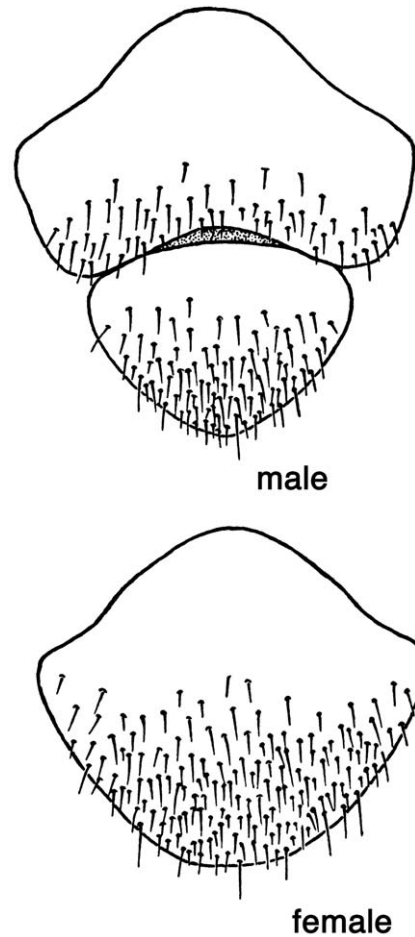

Fig. 7. Abdominal terga of *Cryphalus pubescens* Hopkins: Male, segments 7 and 8 (above); female segment 7 (below). (After Wood 1954:1087.)

Africa and 10 in tropical America. There are no known species in other parts of the world. In the genus *Acanthotomicus* (Ipini), containing 96 species of which 11 occur in tropical America, all of the American species appear to represent a single species group that is also represented in Africa. The 85 Eastern Hemisphere species are mostly in Africa, with small numbers in other species groups in southern Asia, Indonesia, and Australia. The Micracini occur in the Western Hemisphere from southern North America to southern Brazil, and also in tropical Africa. While America and Africa share no genera, almost all American genera share with Africa pairs of very closely related genera. The *Ambrosiodmus* (Xyleborini) contain 17 Central and South American species in the same large species group that occurs in western Africa. A massive ancient connection between eastern South America and western Africa is indicated by these examples.

A much older connection, probably through the Antarctic continent, to Australia is indicated by the occurrence of *Coptonotus* (2 species in South America)

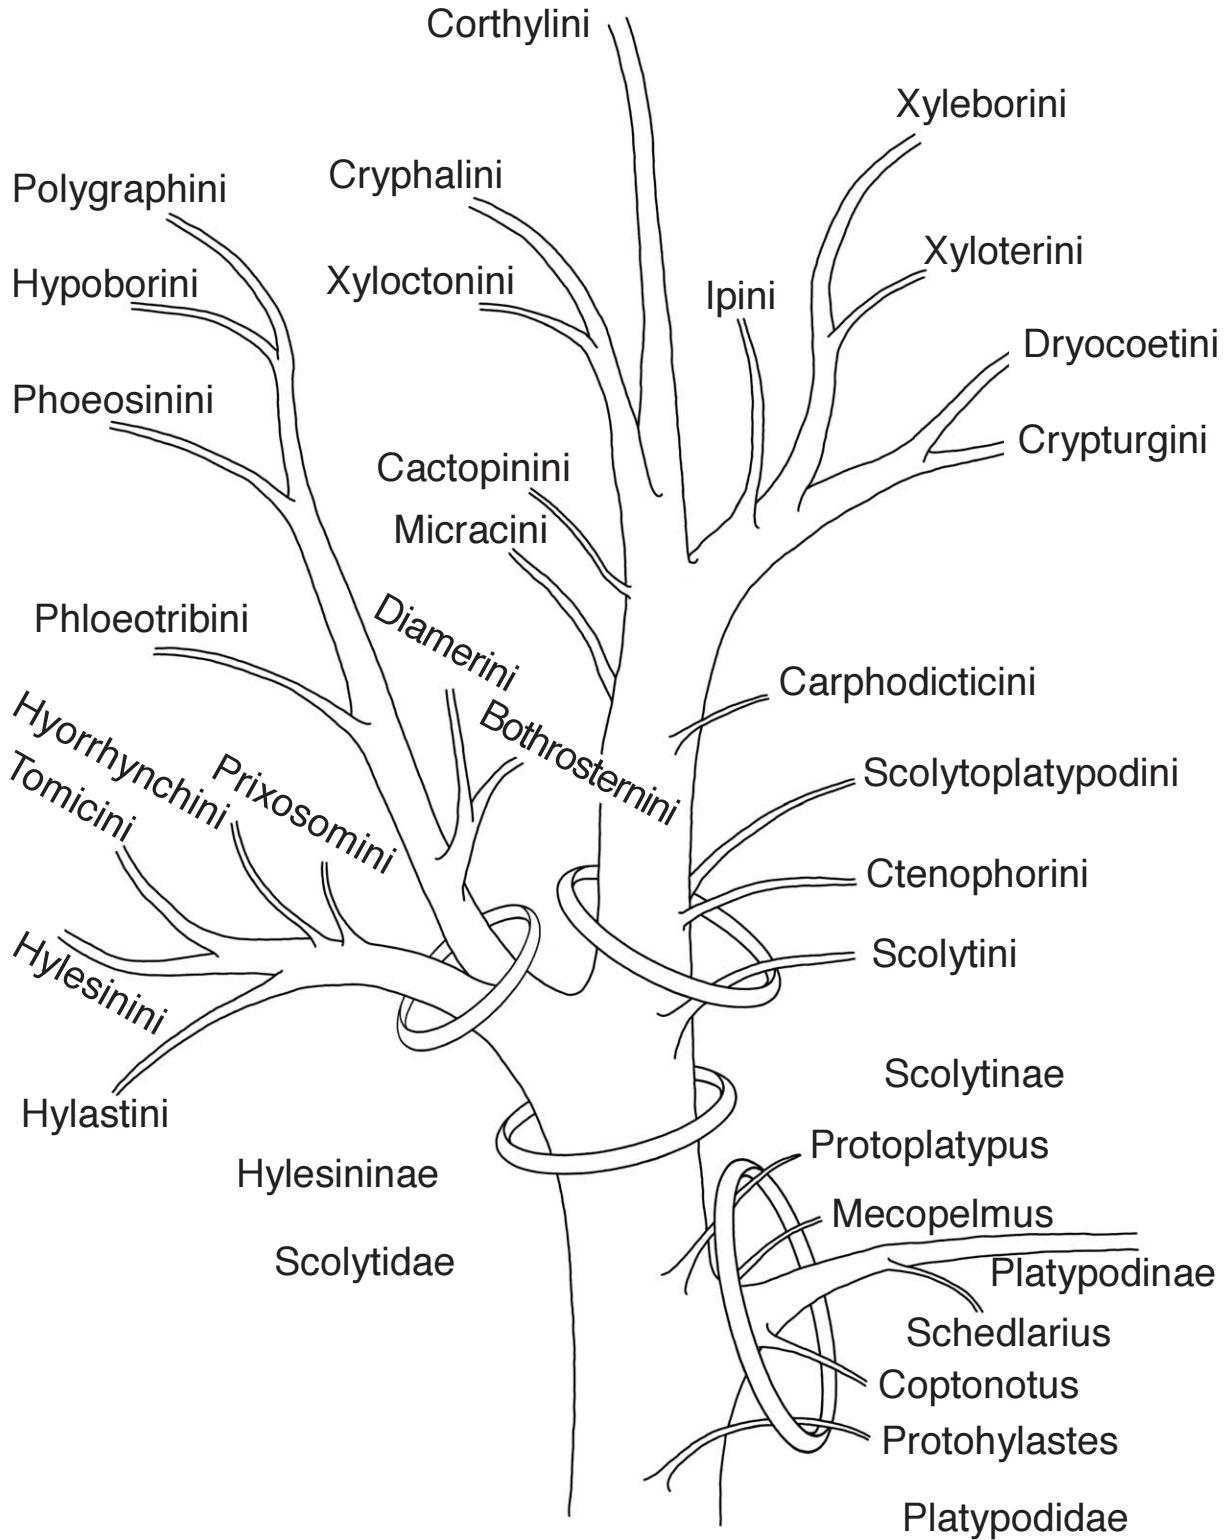

Fig. 8. Dendrogram illustrating possible phylogenetic relationships of major groups within the Scolytidae and Platypodidae. (After Wood 1982.)

and *Protohylastes* (1 or 2 species in Australia and adjacent islands). Allied species are unknown elsewhere. The Phloeotribini occur mostly in South America. One very primitive species that is allied to the South American fauna occurs in Australia. There are no other species in or near Australia or in southeastern Asia. About a dozen species occur in Europe and northern Asia that were obviously derived from North America in comparatively recent geological time.

Other Eastern Hemisphere connections with South America are possible but are not yet fully documented. Examples are: Hylesinini (*Phloeoborus* and *Dactylipalpus*); Tomicini (*Hylurgonotus* and *Pachycotes*); Phloeosinini (*Dendroterus*, *Chramesus*, *Pseudochramesus*, *Cortisinus*, *Cladoctonus*, *Hyleops*, etc.); Hypoborini (many *Liparthrum* in Europe and Asia, 6 in North America, 2 in South America); Carphodicticini (2 in India, 2 in South America); Dryocoetini (*Dendrocranulus* in southern North America and most of South America, *Thamnurgus* and *Xylocleptes* in Europe, southern Asia, and Africa); Cryphalini (*Hypothenemus*, *Trischidias* in America and Africa, greatly complicated by modern commerce and early slave trade); Corthylini (South America and Madagascar, but not Africa). One relict *Pseudothysanoes* in northern China is closely allied to a species in the western USA.

Almost a third of the known South American Scolytidae are in the tribe Corthylini and most of the higher genera (Corthylina) are endemic to South America and Central America north to the southern fourth of Mexico. In this group the species are poorly known from inadequate series and deserve much greater attention.

METHODS

During preparation of this volume, several practices commonly used by others were not followed. These include the following:

(1) Unless specified in the text, all specimens used here were examined by me. No records were based on the identification of others unless I saw the specimens and approved of the record from specimens I had compared to the types. On one or more occasions I visited the British Museum (Natural History), the Schedl Collection at Lienz, Austria, and again after this collection was transferred to the Naturhistorische Museum Wien (Vienna); loans of type material for comparison to my material were received from the Museum National d'Histoire at Paris before 1995 and in 2003; loans were also received from the Universidad de Sao Paulo and from numerous other sources on a limited basis. The loans of unidentified specimens for study came from Dr. Carlos Flechtmann (Brazil), Juan Barriga (Chile), and from many others.

(2) In preparation for this study, I spent, in intensive collecting, 11 months in Venezuela, 6 weeks in Colombia, 18 months in Central America, and 24 months in Mexico.

(3) Measurements of the length of specimens was from the anterior margin of the pronotum to the apex of the elytra, the head was never included, and the unnatural gap, when it occurred, between the posterior margin of the pronotum and the anterior margin of the elytra was deducted. The pronotum length was measured from a point between the median serrations on the anterior margin (when present) to the median posterior margin as seen from a position perpendicular to the median line on the disc; the width was measured at the widest point on the pronotum as seen from a position perpendicular to the median line of the disc. The measurements of the elytra for length were made from the basal margin of interstriae 3 (with the lines on the ocular grid on both left and right elytra) to the apical margin or the longest spine on the declivity, when it projected beyond the apical margin, as seen from a position perpendicular to the suture on the horizontal portion of the disc. The elytra width was taken from a point 1 visible scutellum length behind (caudad from) the posterior margin of the scutellum (with the line on the ocular grid simultaneously at an equal position on both lateral margins). The elytra disc length was made from the elytra length measurement from which the declivity measurement was subtracted; the declivity length was taken from the beginning of the declivity descent (at its base) to the elytra apex as viewed from the same position used to measure disc length. Minor variations in these measurements are to be expected, because no one can repeat the measurements in successive months and get the exact same values. Antennal measurements are less variable due to the less variable structure and position from which measurements are made. Most measurements were rounded off at the first digit to the right of the decimal except when that digit was a 4, 5, or 6, and on almost all measurements of the antennae where the second digit was often used. In some groups, especially in Corthylina, the color pattern on the elytral disc or the position of tubercles on the declivity were described when all punctures were either confused or absent. For those specimens, a knowledge of where the striae or interstriae are normally positioned must be utilized, because no visible orientation structures (such as obsolete striae) exist; however, the pattern or the existence of a tubercle may be of extreme importance to correct identification.

(4) All proportions of features measured were standardized; that is, the width was always divided into the length of the body, antennal club, pronotum, or elytra. The reverse method (length into width) was never used.

(5) When practical, the descriptions were standardized, and the inclusion of features with little or no taxonomic value were reduced or eliminated in order to avoid the illusion of describing differences where none actually exist.

(6) Distributions first give a summary outlining the most distant known limits of the range of the taxon. This is followed by political divisions (countries) presented in alphabetical order. When significant new records and

information were found outside of South America for a South American species, these are listed first. Because most species from tropical America are so poorly known, and in order to reduce the scattering of taxonomic data, species new to science from southern Mexico to Panama found since Wood (1982) was published are included, whether found by me or sent to me. Most keys to species for each genus contain the known species for Central America because of the high probability that these species also occur in South America.

For most species the full collection data are included, as given on specimen labels. Unusually common, widely distributed species, where hundreds of records exist, were reduced to only a list of the countries where they occur. The names of states or provinces were included wherever possible. Locality names and places were as given in *The Columbia Lippencott Gazetteer of the world*, Columbia University Press (1956) or in *Atlante Internazionale*, del Touring Club Italiano, Milano (1956).

(7) The authenticity of data taken from specimen labels is dependent on accuracy of locality, host identification, labeling, clarity of the printing or handwriting, correctness of labels being placed on the pin bearing the specimen, and absence or errors in remounting dislodged specimens from the original pin. Many labeling errors have been published in the literature; a few were detected and corrected in this volume.

(8) All of my studies for this volume were based on observations made with a stereoscopic American Optical microscope at magnifications of 10, 40, 80, and 120X, equipped with an ocular grid that consistently overstated the actual measurement by 0.5 mm in a 10 mm measurement (a 5 percent exaggeration).

(9) My use of the terms "interspace" and "interstriae" are not synonymous, as is the case with some workers. Interspace is a generic term referring to the space between 2 objects (such as the space between 2 punctures on the frons, pronotum, etc.). Interstriae is the space between 2 stria rows of punctures on the elytra; this space can exist only between 2 stria rows; consequently, only the plural form is valid. Occasionally I improperly cite the area between the elytral suture and striae 1 as "interstriae 1." This was done to conserve space, not from my lack of knowledge of correct usage.

(10) In the descriptive treatment of each species, the centered heading is the accepted name for the species treated. This name may be supplemented, for use in this volume only, by "n. status," "n. sp.," "n. comb.," etc. A departure from conventional systematic practice occurs on the first complete line following the centered heading for each species, when the name of the species treated is not given in its original combination, but instead, is listed in its currently accepted form, with the genus name used in the original combination placed in parentheses at the end of the literature citation. This was done because most nonprofessional users of this volume will not be trained in systems. It is a common

error of non-systematicists to assume the original combination to be the accepted correct name. It is hoped that this change will reduce the number of errors in citing the correct names of species.

There is considerable disagreement as to the correct spelling of the name of the former British Guiana. Even the residents of that country disagree on whether it is "Guiana," or "Guyana." The name was consistently spelled "Guiana" in this volume even though it is not the accepted English spelling. Similarly, correspondence with residents have printed the name "French Guyane" on their letterhead even though the name in French is quite different.

SYSTEMATIC SECTION

This is the first noteworthy attempt to comprehensively review and classify all known species of Scolytidae of South America. Minor taxonomic reviews involving some South American species have been made by Eichhoff (1878), Costa Lima (1923–1967), Eggers (1942), and Schedl (1937). Catalogs of the world fauna of Scolytidae, which include South American species, were compiled by Hagedorn (1910) and Wood & Bright (c1992). Most published articles that treat South American Scolytidae consist of isolated descriptions of species new to science, mostly by Eichhoff, Eggers, Schedl, and Wood. In Wood & Bright (c1992), the number of species cited as occurring in South America, in Wood & Bright was 1126. The present volume lists several species new to science that do not occur in South America, mostly from Mexico and Central America. These Mexican and Central American species were included in this volume (1) because of the high probability that they could also occur in South America, (2) because of where they fit in the classification of neotropical species, and (3) to place the descriptions in a major work treating neotropical scolytids, rather than in isolated journals.

Speculation as to the apparent completeness of our knowledge of the scolytid fauna of South America may be of interest, because more than half of the species (56 percent) reported here are known from only 1 specimen or from more than 1 specimen all taken at 1 locality, based on information associated with the compilation of this volume and on my knowledge gained while collecting in tropical America. It is estimated that more than 3000 species of Scolytidae will eventually be found in South America, exclusive of accidentally imported introductions. The study of sibling (or cryptic) species has scarcely begun. The existence of microhabitats in tropical forests is almost infinite when compared to temperate forests. It will take decades of intensive collecting for specialists to train themselves to find many of those microhabitats where unique species live.

ACKNOWLEDGMENTS

My sincere thanks are extended to those who made the effort to become involved in a positive way to make this study possible. In spite of its many weaknesses, these volumes represent a monumental step forward in the progress of forest entomology in South America, because they bring together in one place information that previously was hopelessly scattered worldwide. Special thanks are extended to those collectors who penetrated essentially unexplored areas and took the time to collect, mount, label, and preserve South American Scolytidae for scientific study. Foremost among these has been Carlos A.H. Flechtmann, Department of Plant Protection, FEIS/UNESP, Brasil, who provided almost half of the specimens seen in this study from the southern half of the continent. His collection data that applies to these specimens has been outstanding. Angelo Moreira da Costa Lima was an outstanding pioneer in the study of South American scolytids and did much to focus interest in the study of these insects. Fritz Plaumann, in Brazil, and F. Woytkowski, in Peru, spent many years collecting in South America and sent their specimens to major museums in Europe and America for preservation. Many others, too numerous to mention, also made significant contributions of value to this treatise.

This study could not have been made without the aid of numerous curators of collections where the types of South American scolytids were deposited. Foremost among these is Heinrich Schoenmann, Naturhistorisches Museum Wien (Vienna, Austria), who prepared and sent loans of type and other specimens of Schedl, Eggers, Ferrari, and Eichhoff, and Natalia Vendenberg, U.S. National Museum of Natural History (Washington, USA), for loans of Hopkins, Blackman, and Eggers specimens. The entire staff at the Institut Royal des Sciences Naturelles de Belgique, Brussels, for loans of Chapuis,

Eichhoff, and others that were absolutely vital to this study. The Museum National d'Histoire Naturelle, Paris, France; the Deutsche Entomologische Institute, Munchenberg, Germany, the British Museum of Natural History, London, United Kingdom; and the Museo Nacional de Historia Natural, Santiago, Chile, made significant loans for this study. Numerous other museums permitted me to study their material or made smaller loans that were most sincerely appreciated in this study.

Apparently, due to the lack of staff or of appreciation for the magnitude and depth of this study, numerous requests for loans from the Museum de Zoologie, Universidade de Sao Paulo, Brazil; and the Museo Argentino de Ciencias Naturalis, Buenos Aires, Argentina, brought no response whatever when their cooperation was needed.

Very great appreciation is also expressed to Brigham Young University for space, facilities, and support for this prolonged study. Michael F. Whiting, associate curator of insects, provided necessary oversight, support, and encouragement to the project. Shawn M. Clark, insect collection manager, Life Science Museum, provided much encouragement and advice on technical details for this study to be successful.

For partial funding of this project, I thank the following offices and units within the USDA Forest Service: North Central Research Station (NCRS-4501), Southern Research Station (Southern Pine Beetle Initiative and SRS-4501), Washington Office of Research and Development, and Washington Office of State and Private Forestry.

Financial support for this project was supplied by the US Forest Service, US Department of Agriculture, Washington. Arrangements for and supervision of the project was provided by Robert A. Haack, USDA, Forest Service.

FAMILY SCOLYTIDAE

Scolytidae are members of the Coleoptera superfamily Curculionoidea, in which there is only 1 median, gular suture. This family and the closely allied Platypodidae are the only members of this superfamily in which a pair of pregular sutures (after Hopkins 1911) branch from the anterior end of the gular suture and continue cephalad toward the bases of the mandibles (Wood 1986:6, 27). Massive internal apodemes reinforce these sutures, which do not occur in other Curculionoidea. The triangular pregula occurs between these arms. The tibiae are armed on the apical and lateral margins by unique, socketed denticles in almost all genera except *Scolytus* (they are also absent in Platypodidae). Corbels are never present in either family. The axis of the mandibular hinge is oblique to transverse, the cutting edge is on the mesal margin, and the hypostomal spine (of Cossonininae, etc., Curculionidae) is entirely absent (Wood 1986:10).

Scolytidae are readily distinguished from Platypodidae by the conspicuously shorter tarsal segment 1, segments 2–5 together are conspicuously longer than segment 1. The male spiculum gastrale is present in all Scolytidae; it is almost universally absent in Platypodidae. The eyes tend to be flattened against the head and are more irregular in outline (elongate, reniform, emarginate, etc.) and are rarely subcircular in outline. The larvae have a definite clypeus; in most Platypodidae the clypeus is vestigial and fused to the frons.

A few recent authors, including myself, have placed the Platypodidae as a subfamily of Scolytidae. While this action is probably correct, the present volume does not follow that course. The research needed to document this action has not yet been published.

Approximately 6000 species of Scolytidae are known. These are classified into 2 subfamilies, 25 tribes, and about 227 genera (Wood 1978, 1986, Wood & Bright c1992:1). While the size ranges from 0.53 mm (male *Trischidias*) to 18 mm (*Phloeoborus*), most species are 2.0–4.0 mm in length. Almost all species bore into tissues of their host to form characteristic gallery systems where pairing, mating, and reproduction occur in a constantly changing ephemeral habitat. Adults and larvae

may feed directly on host tissues (phloeophagy, myelophagy, xylophagy, spermophagy) or their gallery walls may be used for propagation of ambrosia fungi, the spores of which are used as food by both adults and larvae. This xylomycetophagous habit appears to have arisen independently at least 7 times within this family. Mating systems are diverse. Primitive genera tend to be bisexual, with loose pair-bonding between male and female. Either sex may initiate a new attack on the host, but the pattern will be constant and often characteristic for a genus or even a tribe. When the male initiates the attack, some genera or species may evolve toward something loosely resembling harem or outbreeding (heterosanguineous) polygyny. When the female initiates the attack, some genera or species may evolve toward inbreeding (consanguineous) polygyny; in this case, males may be dwarfed, anatomically altered, and genetically haploid. In this latter case, males may be produced parthenogenetically then mate with their mother or sisters to produce diploid females. In at least 2 species of *Ips*, females produce both diploid and polyploid females parthenogenetically.

While most species attack dying, unthrifty, weakened, diseased, broken or felled, or otherwise unthrifty trees, some attack and kill healthy, vigorous trees, and a few normally live in healthy, vigorous trees generation after generation without killing the host. The most destructive species have a mutualistic symbiotic relationship with fungi; the fungi actually kill the tree, the beetle is the vector that moves spores from tree to tree.

The need for immediate recruitment of a substantial adult population to overcome the resistance of a chosen host plant is vital to survival in aggressive species and has led to a high level of refinement in the Scolytidae. Pheromones (sex attractants) are produced by both sexes for this purpose. Some species are known to produce a dozen or more separate chemicals, each with its own special target and objective, in this pairing-mating interaction between the sexes. Pheromones may be less effective in tropical climates (possibly due to excessive rainfall and/or humidity) and are unknown in inbreeding species.

KEY TO SUBFAMILIES, TRIBES

(Modified from Wood 1978, 1986)

- 1. Basal margin of each elytron separately procurved and armed by a series of marginal crenulations (or less commonly by a continuous elevated costa in some *Bothrosternini*), usually with a scutellar emargination between them; scutellum usually small and rounded, depressed, or absent in some groups; pronotum weakly if at all declivous on anterior half, usually unarmed but crenulations sometimes present on anterolateral areas; head usually visible from above, somewhat wider; protibia usually wider; scales or deeply divided setae a common feature (subfamily **HYLESININAE**) 2
- Basal margins of elytra forming a straight, transverse line across the body, unarmed, rarely (some *Scolytini*, *Ctenophorini*, *Cryphalini*) with a weakly elevated continuous line; scutellum usually large, flat (rarely absent or highly modified in some *Xyleborini*); pronotum weakly to strongly declivous on anterior half and usually armed by many asperate crenulations, particularly on median half; head usually partly or entirely concealed from dorsal aspect, somewhat narrower; protibia usually narrower; scales or deeply divided setae an uncommon feature (subfamily **SCOLYTINAE**) 9
- 2(1). Scutellar area of metanotum and its postnotum separated by a suture-like intersegmental membrane; posterior part of scutoscuteilar suture strongly curved mesad to a point near crest of scutellar groove then continuing cephalad parallel to this costa for about two-thirds of metanotum length (except much less in *Phrixosomini*); metapleural suture descending subvertically from pleural wing process to metepisternal groove formed to receive corresponding costal groove and flange of elytron then abruptly angled and continued caudad along this groove to a point near pleural coxal process; scutellum visible; funicle 6- or 7-segmented or if 5 segmented then male frons not impressed, and antennal club symmetrical 3
- Scutellar area of metanotum and its postnotum completely fused on at least median third, intersegmental suture usually obsolete; scutoscuteilar suture less strongly curved, approaching costa of scutellar groove more gradually and continuing cephalad parallel to it for less than half length of metanotum (it never reaches margin of this groove in some groups); metapleural suture sometimes as described above, but more commonly running a more direct route from pleural wing process to pleural coxal process, often remote from locked position of costal margin of elytra for most or all of its course; scutellum either not visible or if visible, then funicle 5-segmented and male frons impressed (*Bothrosternini* with 6-segmented funicle but with a distinctive protibia) 6
- 3(2). Eye completely divided by an emargination, halves widely separated; scutoscuteilar suture remote from costa of scutellar groove; crenulations on basal margins of elytra low, often poorly formed; precoxal ridge on prothorax never present; antennal funicle 6-segmented; in *Guttiferae* hosts **Phrixosomini**
- Eye entire to feebly emarginate; scutoscuteilar suture parallel to costa of scutellar groove for two-thirds length of notum; precoxal ridge on prothorax present or absent; antennal funicle 5- to 7-segmented 4
- 4(3). Prothoracic precoxal area rather large, its lateral margins strongly, sharply elevated from anterior margin to coxae; crenulations on elytral bases usually poorly developed; antennal funicle 7-segmented, club conical, segment 1 almost as long as others combined; head somewhat prolonged, subrostrate, frons never sexually dimorphic; eye entire, rather short; in *Pinaceae* hosts **Hylastini**
- Prothoracic precoxal piece small, short, its lateral areas either elevated into a precoxal ridge or not; crenulations on elytral bases more conspicuously elevated, forming a definite row; antennal funicle variable, 5- to 7-segmented, club weakly to moderately flattened; head less distinctly rostrate, male frons usually impressed, eye oval to elongate, entire to feebly emarginate 5

KEY TO SUBFAMILIES AND TRIBES

- 5(4). Pronotum asperate on anterior areas (except asperities absent in *Hylastinus*); prothorax with elevated costate ridge from coxa to anterior margin; antennal funicle 6- or 7-segmented; mesal surface of elytra at base of suture immediately behind scutellum with an interlocking series of nodules and cavities, this lock interrupts groove and flange of suture (not visible when elytra locked in position) **Hylesinini**
- Anterolateral areas of pronotum usually unarmed; precoxal costa on prothorax absent; funicle 5- to 7-segmented; mesal surface of elytra at suture often with interlocking groove and flange continued to base without a series of nodules or cavities immediately behind scutellum . . . **Tomicini**
- 6(2). Outer apical angle of protibia with a curved bifid process, meso- and metatibiae with 1 or 2 (usually smaller) curved spines on outer apical angle extending beyond level of spine on inner apical angle; pronotum smooth or longitudinally strigose; funicle 6-segmented; lateral prosternal area usually subacutely elevated from coxa to anterior margin; anterior coxae rather widely separated; crenulations on elytral bases rather small or (rarely) replaced by a continuously elevated costa; eye entire **Bothrosternini**
- Outer apical margin of protibia armed by several teeth of about equal size, none of them extending beyond tarsal insertion; funicle 4- to 7-segmented; prosternal area with margins rounded, costa obsolete; eye varying from entire to emarginate to divided 7
- 7(6). Scutellum obsolete, elytral bases only slightly if at all emarginate at suture; tarsal segment 3 slender; mesal surface of elytra at suture usually without a special lock, groove and flange extend to base at position of scutellum; eye sinuate or entire; pronotum armed by a few scattered or clustered asperities; crenulations at bases of elytra restricted to area between suture and interstriae 5; funicle 3- to 5-segmented **Hypoborini**
- Scutellum visible, elytral bases notched for its reception; tarsal segment 3 stout, usually bilobed (slender in *Chramesus*); mesal surface of elytra at suture immediately behind scutellum with a series of interlocking nodules and cavities 8
- 8(7). Antennal club constricted at sutures and movable at intersegmental lines, segments frequently, strongly, asymmetrically extended as sublamellate lobes **Phloeotribini**
- Antennal club segments immovably, broadly fused at sutures; antennal club sutures often partly or entirely obsolete **Phloeosinini**
- 9(1). Lateral margins of pro- and metatibiae unarmed except for a single, apical, spinelike process that curves toward and extends beyond process of inner apical angle; lateral margins of pronotum subacutely elevated, costate; pleural suture descending subvertically from pleural wing process to groove receiving groove and flange on costal margin of elytra, at this point suture turns abruptly and follows groove caudad to metapleural coxal process; funicle 7-segmented, sutures of antennal club strongly procurved or obsolete **Scolytini**
- Lateral margin of protibia armed by more than 1 denticle, none of which exceed or curve toward inner apical process; pleural suture less strongly angulate, groove receiving flange of costal margin of elytra displaced ventrad from course followed by pleural suture; lateral margins of pronotum subacutely raised or not, antenna variable 10
- 10(9). Metepisternum visible throughout its length, slightly more than its dorsal half covered by elytra when in locked position, either with a conspicuous groove for reception of costal flange throughout its length or else groove represented at its anterior end by a denticulation or costate remnant near anterior end of metepisternum; antennal club varying from flat to obliquely truncate 11
- Metepisternum largely covered by elytra, usually not visible on its posterior half, its groove for reception of costal flange obsolete, a small, transverse callus (*Cryphalini*) or a small transverse groove (*Corthylini*) at anterior end of metepisternum; antennal club strongly flattened; antennal funicle 1- to 5-segmented, club never obliquely truncate 15

- 11(10). Lateral margins of pronotum subacutely elevated, basal margins of elytra usually finely elevated; procoxae rather widely separated; protibia with prominent outer apical process recurved, usually extending beyond tarsal insertion, posterior tibia tapered on apical third and armed by several small, socketed denticles; funicle 6- or 7-segmented; tarsi often retractable into tibial grooves **Ctenophorini**
- Lateral and basal margins of pronotum rounded; procoxae subcontiguous (except most Micracini and a few Xyleborini); protibiae with outer apical angle inconspicuous, armed by several small, socketed denticles; funicle 2- to 6-segmented; tarsi not retractable 12
- 12(11). Procoxae moderately separated; protibia with sides parallel, usually armed by denticles only on apical margin or posterior face; funicle 6-segmented; female frons often concave, male frons rarely concave (2 *Pseudothysanoes*) **Micracini**
- Procoxae contiguous (except Carphodicticini, some Xyleborini); protibia much wider apically, armed on lateral margin by several denticles; female frons rarely concave (a few Dryocoetini), male frons often concave, funicle 2- to 5-segmented 13
- 13(12). Eye emarginate, funicle 5-segmented; male dwarfed, deformed, and flightless; female meso- and metathoracic tibiae expanded to just beyond middle then arcuately tapered to apex, its apical two-thirds on outer margin armed by a row of numerous small, closely set teeth of equal size, these usually supplemented by a row of submarginal setae on posterior face; preular area depressed (except *Premnobius*); wood-boring, xylomycetophagous; male absent from parental gallery except as offspring **Xyleborini**
- Meso- and metathoracic tibiae more slender, more abruptly narrowed on apical fourth, lateral and apical margins armed by fewer, coarser teeth; eye sinuate on anterior margin; pronotum sometimes with raised line on basal or lateral margin; preular area not depressed; sexes of similar size and body form; habits varied but never xylophagous (woodboring) or xylomycetophagous 14
- 14(13). Eye shallowly sinuate to shallowly emarginate, its lower half distinctly narrower than above; protibia with 3–4 socketed teeth; antennal club rarely obliquely truncate (some *Orthotomicus*); procoxae contiguous, intercoxal piece longitudinally emarginate to absent, never complete; elytra moderately sulcate to elaborately excavated, with lateral margin usually armed by tubercles or spines; pronotum more strongly declivous and armed on anterior third, asperities usually larger (*Carphodicticini*) **Ipini**
- Eye sharply, rather deeply emarginate, lower half almost as wide as upper half; protibiae usually with four or more socketed teeth; procoxae either contiguous or distinctly, narrowly separated; elytral declivity flattened to convex, usually unarmed by spines or large tubercles (some male *Dendrocranulus* with 1 pair of spines are exceptions); pronotum either evenly arched from base to anterior margin or less strongly declivous on anterior third, asperities, when present, usually fine and abundant; antennal funicle 5-segmented, club more nearly obliquely truncate **Dryocoetini**
- 15(10). Costal margin of elytra slightly to moderately ascending from base of declivity to apex; basal end of metepisternum armed by a callus or partial groove of degenerating metepisternal spine; sutures on posterior face of antennal club more strongly displaced toward apex; funicle 3- to 5-segmented; tibiae more strongly flattened, usually armed by more than 4 denticles; vestiture commonly includes scales; eye usually entire, less commonly emarginate (*Hypothenemus*) **Cryphalini**
- Costal margin of elytra descending toward apex (except *Brachyspartus*); basal margin of metepisternum with a small, transverse groove (concealed when elytra in locked position), elytra in locked position more completely cover metepisternum, less than anterior third exposed on its ventral half; sutures on posterior face of antennal club only slightly displaced toward apex; funicle 1- to 5-segmented; tibiae more slender, rarely armed by more than 4 socketed denticles; vestiture rarely including scales; eye emarginate **Corthylini**

SUBFAMILY HYLESININAE

The concept of the subfamily Hylesininae presented here is that of Wood 1978, 1982, 1986; and Wood & Bright c1992. It may differ radically from the work of other authors.

The Hylesininae all have a row of rather distinctly elevated crenulations along the basal margin of the elytra. Each elytron may bear as few as 4 crenulations or more than 15. In *Hylastes* (Hylastini), they are poorly formed but are quite distinct. Some members of *Cnemomyx* (Ctenophorini, Scolytinae), allies of *galeritus*, also have well-formed crenulations, but these species are placed in Scolytinae because of the occurrence of

other sets of characters that clearly associate them with Scolytinae. This might indicate an evolutionary path along which Hylesininae evolved. The *Pycnarthrum* (Ctenophorini) also exhibit additional characters that suggest a connection to the Hylesininae.

Crenulations on the elytral base appear to aid the beetle in maintaining its position in the gallery when a predator attempts to enter or to pull the beetle from the defended entrance hole. The short, stout, subglobular body form apparently enhances the effectiveness of this trait.

TRIBE HYLASTINI

The distinctive antennae, tibiae, poorly developed crenulations on the elytral bases, and habits distinguish this tribe. Their natural distribution is restricted to the Northern Hemisphere, but commerce has introduced 1 species to *Pinus* plantations in the Southern Hemisphere.

GENUS *HYLASTES* ERICHSON

Hylastes Erichson, 1836:47. Type-species: *Bostrichus ater* Paykull, subsequent designation by Westwood 1838:39, Thomson 1859:146 (References in Wood & Bright c1992:43)

Description: Frons not sexually dimorphic; eye oval, entire; antennal scape elongate, funicle 7-segmented; precoxal ridge on prothorax strongly, acutely elevated from coxa to anterior margin of prothorax. Protibiae large, with several socketed teeth. Basal crenulations on elytra poorly developed; declivity convex, sculpture simple.

Distribution: About 35 species occur mostly from northern Africa through Europe to northern Asia, and in North America. At least 1 species (*ater*) has spread through commerce to South Africa, New Zealand, and South America (Chile).

Biology: Most species confine their breeding activity to Pinaceae roots at or below the ground level. A few also infest prostrate logs where the lower surfaces contact the ground. Newly emerged adults of a few species form maturation feeding tunnels in seedlings, particularly in nursery stock. Because of their subterranean habit they are usually overlooked until infestations are severe. Flying adults are occasionally attracted to light at night.

Hylastes ater (Paykull)

Plate I

Hylastes ater (Paykull), 1800:153 (*Bostrichus*). Lectotype ♀; Surrey-Bramshill, England; type not located, designated by Lekander 1965: 185 (Synonymy and references in Wood & Bright c1992:45–49)

Hylesinus chloropus Duftschmidt, 1825:102. Syntypes, sex?, Europe, not located

Hylastes pinicola Bedel, 1888:390. Syntypes, sex?, not located, replacement name for *ater* Paykull

Diagnosis: Imported to Chile *Pinus* plantations from Europe or northern Asia. Characters described below distinguish it from all other South American species.

Male: Similar to female except last visible abdominal sternum rather broadly impressed (broadly convex in female).

Female: Length 3.5–4.4 mm, 3.1 times as long as wide; color almost black, elytra slightly lighter and often somewhat reddish brown. Head subrostrate; frons planoconvex, with a fine, acutely elevated, median carina on lower half; antennal club small, conical, basal segment occupying almost half its length. Pronotum 1.2 times as long as wide, coarsely, deeply, closely punctured, glabrous. Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures rather coarse, deep; interstriae twice as wide as striae, weakly subcrenulate (at 80X), with numerous, small, confused punctures; vestiture short, sparse, hairlike, length of each seta almost equal to diameter of a stria puncture. Tibiae large, much wider on apical third.

Distribution: Europe and N Asia, introduced to South Africa, New Zealand, and South America (Chile).

Chile: Lirquen, 12-VIII-1984, Pino Insigne, Mathei; Melpilla, Curacavi, 18-1987, J. Solervicens; Pto. Valpo y bavco, 21-IV-1987, R.H. Gonzalez; Valparaiso, VII-1981, *Pinus* sp., P. Ojeda; Valparaiso, 20-III-1988, trampa, J. Godoy.

Hosts: *Pinus* spp., in plantations.

Biology: All species are monogynous and breed in

the phloem tissues of roots of their hosts. In tropical areas they may also breed in logs where the bark is in contact with the ground.

Notes: The above treatment was based on my series of 20 specimens from Europe and Asia, and on 13 specimens from Chile.

TRIBE HYLESININI

Description: Male frons obscurely to deeply and extensively impressed, female flat to variously convex; eye oval to elongate, entire to feebly sinuate on anterior margin; antennal scape very short to elongate, funicle 6- or 7-segmented, club conical to moderately flattened, symmetrical or nearly so, 2 or more sutures indicated; procoxae narrowly to moderately separated, prothoracic precoxal ridge moderately to very strongly, acutely elevated; pronotum armed by a few asperities (except absent in *Hylastinus*); mesoscutellar area separated from post-

notum by a distinct suture; mesal surface of sutural groove of elytra just behind scutellum interrupted by a series of interlocking nodules and cavities; tarsal segment 3 usually wider than 2, often bilobed.

Biology: All species are monogynous; all are phloeophagous except the xylophagous *Phloeoborus*. The parental galleries are mostly biramous, although a few species that make a large turning niche near the entrance hole may have monoramous galleries.

Key to the Genera of Hylesinini

- 1. Antennal club subconical, with 3 sutures indicated; posterior face of protibia flattened to weakly convex, smooth, lateral margin armed by socketed teeth; frons convex in both sexes; pronotum without asperities; Chile; Leguminosae herbs or subshrubs; 2.0–2.5 mm **Hylastinus**
- Antennal club moderately to strongly flattened, with 2 or 3 sutures weakly indicated; posterior face of protibia somewhat convex, often indistinctly to rather coarsely, closely tuberculate; pronotum with at least a few crenulations; male frons modestly to strongly concave 2
- 2(1). Female propleuron without a mycetangium; tibiae armed by socketed teeth; eye entire, oval; elytral vestiture abundant; phloeophagous, mostly in Oleaceae; 1.7–4.8 mm **Hylesinus**
- Female propleuron with a large mycetangium; tibiae without socketed teeth, posterior face coarsely tuberculate; eye large, elongate; elytra usually glabrous or nearly so; xylophagous; 5.0–12.0 mm **Phloeoborus**

GENUS *HYLASTINUS* BEDEL

Hylastinus Bedel, 1888:388. Type-species: *Ips obscurus* Marsham, monobasic (References in Wood & Bright c1992:64)

Diagnosis: This European genus is unrelated to other members of the neotropical fauna. It is easily distinguished by characters summarized in the above key and by its habits.

Description: Sexes similar. Frons convex, with a dis-

tinct interocular impression; antennal scape elongate, funicle 7-segmented, club conical with 3 sutures; pronotum without any asperities; precoxal ridge on prothorax acute, strongly developed; elytra striate, declivity convex.

Distribution: Wood & Bright (c1992:64–67) list 4 species from Europe, N Africa, and Asia Minor, with 1 species (*obscurus*) introduced through commerce to North and South America.

Biology: Adults of *obscurus* bore into roots of their Leguminosae hosts.

Hylastinus obscurus (Marsham)

Plate I

Hylastinus obscurus (Marsham), 1803:57 (*Ips*). Syntypes, sex?; type-locality unknown, presumably England; syntypes presumed to be in BMNH, London (Synonymy and references in Wood & Bright c1992:64–67)

Scolytus crenatus Olivier, 1795:12. Syntypes, sex?; Paris, France; presumably in MNHN, Paris, not located; preoccupied by Fabricius 1787:37

Dermestes trifolii Muller, 1803:47. Syntypes, sex?; central Europe; not located

Hylesinus crenulatus Duftschmidt, 1825:104. Syntypes, sex?; Linz, Austria; probably MNB, Berlin, not located

Hylurgus fuscescens Stephens, 1830:365. Syntypes, sex?; London, England; BMNH, London

Hylurgus piceus Stephens, 1830:365. Syntypes, sex?; London, England; BMNH, London

Hylastinus kroaticus Fuchs, 1912:49. Syntypes, sex?; Croatia; not located

Hylastinus pilosus Eggers, 1944:140. Holotype ♂; Algeria; USNM, Washington

Diagnosis: Introduced from Europe; easily distinguished by the habits; by the size; and by the acute, strongly elevated precoxal ridges on the prothorax.

Male: Similar to female except for abdominal terga 7 and 8.

Female: Length 2.0–2.5 mm, 2.2 times as long as wide; color dark brown. Frons convex, with a small, conspicuous interocular impression; surface coarsely reticulate, with close, coarse, shallow, obscure punctures; vestiture hairlike, short, inconspicuous. Pronotum 0.9 times as long as wide; widest one-third pronotum length from base; surface coarsely, closely, deeply punctured, interior of most punctures obscurely reticulate; vestiture hairlike, moderately long, rather abundant. Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; striae weakly impressed, punctures large, deep; interstriae distinctly narrower than striae, feebly convex, punctures rather fine, part of them with anterior margin subcrenulate, tuberculate toward declivity. Declivity convex, steep; striae slightly narrower, interstriae more strongly convex than on disc, each interstriae with a row of fine, pointed tubercles; vestiture of coarse, hairlike, interstitial setae, each about equal in length to diameter of a striae puncture, and medial rows of interstitial hair each about twice as long as ground setae.

Male: Similar to female except for abdominal terga 7 and 8.

Distribution: Europe, parts of northern Africa, and Asia. Introduced into North America, South America (Chile), etc.

Chile: Carillanca (Experiment Station north of Temuco); Malleco, Ericilla, IV-1977, trebol rosada; Victoria, Malleco Prov., 21-III-1973, *Trifolium pratense*, T. Posado [Schedl 1978:293].

Hosts: Listed in Europe include *Medicago sativa*, *Melilotus* sp., *Ononis natrix*, *Spartium scoparium*, *Trifolium pratense*, *Ulex europaeus*, *Cytisus bifloris*, *C. hirsutus*, *C. laburnum*, *C. nigricans*.

Biology: New parent adult tunnels are bored into the rhizomatous taproots of unthrifty or older plants in Europe and North America in the spring. Parent galleries are of the biramous type with eggs deposited in niches along the margins. Larvae mine at random through the root tissue. Pupation occurs during late summer. There is 1 generation each year. Adjustments in the life cycle to the climate of Chile have not been reported.

Notes: The above treatment was based on more than 100 specimens from North America and Europe, and on 8 specimens from Chile.

GENUS *HYLESINUS* FABRICIUS

Hylesinus Fabricius, 1801:390. Type-species: *Hylesinus crenatus* Fabricius, subsequent designation by Westwood 1838:39 (Synonymy and references in Wood & Bright c1992:74–90)

Leperisinus Reitter, 1913:41. Type-species: *Bostrichus fraxinus* Panzer = *Hylesinus varius* Fabricius, subsequent designation by Swaine 1918:70

Apidocephalus Wickham, 1916:18. Type-species: *Apidocephalus hydropticus* Wickham, monobasic

Diagnosis: Distinguished by the moderately ascending abdomen and costal margin on posterior part of elytra; ground vestiture of abundant scales, rows of erect interstitial setae usually present; eye oval, entire; antennal funicle 7-segmented, club distinctive.

Description: Frons sexually dimorphic, male variously impressed to deeply concave, female convex; eye oval, entire; scape elongate, funicle 7-segmented, club moderately flattened, slightly asymmetrical, with 2 or 3 sutures; pronotum wider than long, anterolateral areas armed by several crenulations; elytra striate, declivity convex, moderately steep, costal margin ascending on posterior third, abdomen ascending almost half distance to meet apex of elytra; vestiture of ground cover of short scales, interstitial rows of erect hair or scalelike setae usually present.

Distribution: There are 41 species listed worldwide by Wood & Bright (c1992:74–90), most of which occur from Europe and Asia to Australia and from North America south to Guatemala. Four species have been reported from South America, although only 1 of them appears to actually belong to this genus.

Biology: members of this genus breed in Oleaceae and Flindersiaceae hosts. All are monogynous and phloeophagous. The 20 or more species personally known to me form transverse, biramous parental galleries in the cambium area, which deeply engrave the wood. larval mines extend above and below the primary gallery, following the grain of the wood, and tend to be rather straight. It has been reported that some species pass seasons of stress (winter, dry season) in maturation tunnels in the outer bark at the base of their brood tree, others are reported from litter on the forest floor. It is probable that tropical species continue without interruption from 1 generation to the next.

Hylesinus toranio (Danthione)

Plate I

Hylesinus toranio (Danthione), 1788:270 (*Byrrhus*). Syntypes, sex?; Europe, not located (Synonymy and references in Wood & Bright c1992:83–85)

Bostrichus oleiperda Fabricius, 1792:366. Syntypes 2, sex?; Gallia meridionali; UZM, Copenhagen

Ips scaber Marsham, 1802:56. Syntypes, sex?; Horto Kensingtoniano, England; presumably BMNH, London

Hylesinus suturalis Redtenbacher, 1842:21. Syntypes, sex?; Europe; not located

Hylesinus esau Gredler, 1866:370. Syntypes, sex?; Tirol, Austria; not located

Hylesinus antipodus Schedl, 1951:17. Lectotype ♂; Rengo, Chile; Museo Nacional de Historia Natural, Santiago, present designation (References in Wood & Bright c1992:75). *New synonymy*

Diagnosis: This introduced species is the only member of the genus in South America; it is distinguished by characters presented in the key to genera.

Male: Similar to female except frons rather strongly, broadly concave from epistoma to slightly above upper level of eyes, with no indication of a median carina, punctures minute and setae almost obsolete.

Female: length 1.9–2.8 mm, 1.6 times as long as wide; color very dark brown, with vestiture somewhat variegated (pale, dark brown intermixed), vary individually and with age. Frons moderately impressed, median carina rather short, surface with at least some reticulation, punctures small, rather sparse. Pronotum with posterior area rather weakly projecting into scutellar notch; asperities in anterolateral areas moderately large and numerous, median half somewhat rugose, punctures large and with no reticulation; vestiture of fine, long hair, Elytra with about 12 larger basal crenulations; striae narrowly, rather deeply impressed; interstriae about 2–3 times as wide as striae, each armed on posterior half by a row of narrowly subcrenulate tubercles, these continue to base but increasingly confused cephalad, also with numerous fine punctures; vestiture conspicuous, moderately long, varying from pale to brown in color and from slender to rather stout hair.

Distribution: Europe, also to northern Africa, Asia Minor, and Japan. Introduced into South America (Argentina, Chile).

Argentina: “Argentina” (Wood & Bright c1992:80).

Chile: Marchigue, Colchagua, 2-XII-1977, ex olive, R. Charlin; Rengo, XII-1947.

Hosts: Recorded in Europe from *Fraxinus* spp., *Fagus* spp., *Olea Europea*, *Syringa* spp.

Notes: Much of the literature is recorded under the name *H. oleiperda* Fabricius, a junior synonym. The name *antipodius* Schedl, described from Chile, is also a synonym of *toranio*. Two male cotypes (actually syntypes) and 1 female of *antipodius* from the Museo Nacional de Historia Natural, Santiago, were examined and compared by me to my series from Europe. One of these male cotypes is here designated as the lectotype of *antipodius*. Although Schedl referred to a holotype, he never designated a holotype or lectotype.

Species Not Seen

Hylesinus bicolor Philippi & Philippi

Hylesinus bicolor Philippi in Philippi & Philippi, 1864:375. Syntypes; Prov. Valdivia invenit orn. Landbeck [Chile]; NHH, Santiago; pre-occupied by Brulle (1832:250)

Not located. If it is not a synonym of an introduced species, it probably belongs to another genus.

Excluded Species

Acacacis atomarius (Chapuis), n. comb.

Hylesinus atomarius Chapuis, 1860:29. Syntypes 2 ♂♂, 2 ♀♀; “Bresil”; IRSNB, Brussels (References in Wood & Bright c1992:75)

Acacacis abundans Lea, 1910:149. Syntypes, sex?; Hobart, Mt. Wellington, etc.; SAM, Adelaide (References in Wood & Bright c1992:192). *New synonymy*

Reported here for the first time is an error in identification and in labeling of an Australian species, *Acacacis abundans* Lea, which has been listed as thought it came from “Bresil.” The 2 male and 2 female syntypes were examined and were compared by me to a long series of this species I collected in Queensland, Australia, which was previously known as *Acacacis abundans*. Except for these 4 specimens, the species is not known from South America. The report from “Bresil” is regarded as an error in labeling. Therefore, this species is removed from the South American fauna. The genus *Acacacis* is a member of the tribe Diamerini that is known only from Asia in the Indo-Malayan and Austro-Malayan subregions, and from Africa.

GENUS *PHLOEOBORUS* ERICHSON

Phloeoborus Erichson, 1836:54. Type-species: *Phloeoborus rudis* Erichson, subsequent designation by Hopkins 1914:126 (Synonymy and references in Wood & Bright c1992:97–101)

Phloeotrupes Erichson, 1836:54. Type-species: *Phloeotrupes grandis* Erichson

Diagnosis: Recognized by the very large size and stout body form; by the modestly flattened, conical antennal club, with 2 sutures weakly marked; by the large female propleural mycetangium, which is ornamented by setae; and by the retractable metatarsi.

Description: Body length 5.0–14.0 mm, dark brown to black. Frons sexually dimorphic, male variously impressed, female convex; antennal scape elongate, funicle 7-segmented, club conical but moderately flattened, weakly marked by 2 sutures, closely, uniformly covered by abundant micropile; eye variously elongate (often subcontiguous above and below). Pronotum variable, with or without asperities; propleuron with a large mycetangium ornamented by hair in female, rarely present in male. Elytra with crenulations on bases poorly formed; striae usually impressed, punctures small to obsolete; declivity variously convex; vestiture usually obsolete.

Distribution: This exclusively neotropical genus is known from 24 species and is restricted to tropical rain

forests (Wood & Bright c1992:97–101) from Mexico (Veracruz) to northern Argentina.

Biology: Adults and larvae are xylophagous. They bore into broken, uprooted, or felled logs or limbs larger than 15 cm in diameter on the lower side at or near the site of contact with the ground. The radial tunnel extends inward about 2–5 cm into the xylem then branches into 2 to several short arms. The parental chambers are stained black by fungal growth, but the spores are apparently not used directly as food. Superficial studies suggest that the fungi act upon the xylem to soften and/or enhance its nutritional value. Eggs are placed in niches that are randomly distributed from which larvae bore long, meandering tunnels through the wood. Tissue decay is unusually rapid in

the vicinity of larval mines, but ambrosial growth does not appear inside the tunnels. Mycelial growth, however, is conspicuous inside of pupal chambers. Pupation may occur anywhere within the log, not necessarily near the surface. One generation each year appears synchronized with the dry season. By the time pupation occurs, tissue deterioration has advanced to the point where large logs can be torn apart by hand.

Notes: Because of the large size of specimens, this genus has attracted much attention and because erroneous identifications of species have listed occurrence of specimens taken from areas far beyond their natural distributions, all known species are treated here in the hope that order might be had in the classification of species.

Key to the Species of *Phloeoborus*

- 1. Pronotum unarmed by asperities; striae usually wider; punctures more distinct; pronotum somewhat triangular, surfaces of pronotum and elytra smooth, shining 2
- Pronotum armed by asperities at least on anterolateral areas, these usually accompanied by subasperate crenulations to or near base; pronotum somewhat quadrate; striae usually narrower; punctures minute to obscure; elytra and (usually) pronotum surfaces reticulate (1 exception) 10
- 2(1). Eyes narrowly separated above, spaced by distance equal to less than 3 diameters of a facet; interstitial crenulations on disc about half as wide as an interstriae, their posterior, subvertical faces marked by a puncture, most punctures bearing a tiny seta, its length shorter than diameter of a puncture 3
- Eyes more widely separated above by a distance equal to or greater than width of an eye; interstitial crenulations on disc more gently sloped, usually without a discernible puncture or seta . . . 7
- 3(2). Summits of interstitial crenulations on disc rounded, posterior face of each crenulation oblique 4
- Summits of interstitial crenulations on disc subacutely elevated, their posterior face vertical, particularly coarse near base 5
- 4(3). Interstriae mostly smooth, with almost no reticulation, crenulations more numerous, more closely spaced, their crest more conspicuously transverse; median carina in frontal impression more strongly, acutely elevated; Costa Rica to Bolivia, Paraguay, Argentina; 7.0–10.0 mm *signatus* **Strohmeyer**
- Interstriae weakly, minutely, mostly reticulate on disc and declivity, tubercles higher, less numerous, mostly less than twice as wide as thick; median carina on frontal impression weak, obtuse; Costa Rica; 7.8 mm *willei* **Wood**
- 5(3). Elytral declivity dull, rather strongly reticulate on both striae and interstriae, reticulation gradually reduced in disc until at base only interior of interstitial punctures with reticulation; color brown; Guiana; 6.6 mm *intermedius* **Eggers**
- Elytral surfaces mostly shining, weak reticulation often present on declivity and obscurely on posterior disc, interiors of punctures on discal interstriae never reticulate; color dark brown to black 6
- 6(5). Strial punctures on disc larger, interstriae twice as wide as striae; strial punctures within a row on disc separated by normal groove; interstitial crenulations on disc narrower, most less than one-third as wide as an interstriae, punctures behind crenulations usually present, distinct; reticulation on declivity obscure to absent; Belize to Argentina; 6.4–11.7 mm *rudis* **Erichson**

- Strial punctures on disc small, interstriae two and one-half to three times as wide as striae; strial punctures within a row mostly separated by a low, subacute, transverse partition; interstitial crenulations on disc larger, almost half as wide as an interstriae, crenulations averaging higher, more acute, punctures behind crenulations more obscure, often obsolete; reticulation on declivity usually present in some areas; (female not seen) Brazil (Sao Paulo to Rio de Janeiro); 8.3–8.5 mm
..... *freyi* Schedl
- 7(2). Frons with a strongly elevated, acute median carina extending from epistomal margin to upper level of eyes; pronotum smooth, shining, a puncture almost equal in width to combined diameters of four facets of an eye; antennal club wider than long, apex narrowly rounded; Brazil; 8.8–9.5 mm
..... *procerus* (Erichson)
- Frons with median carina extending from epistomal margin half distance to upper level of eyes; pronotum smooth, shining, largest punctures about equal in width to one facet of eye; interstitial surface undulating or with crenulations low, confused 8
- 8(7). Pronotum at or near anterior margin with punctures very small (diameter about equal to 1 facet of eye), circular in outline; discal interstriae 1–8 with rather close, transverse impressions at each puncture causing surface to undulate from base to declivity, none of these undulations crenulate; antennal club as wide as long, its apex broadly rounded; Brazil (Sao Paulo) to Paraguay; 7.9–12.5 mm *grandis* (Erichson)
- Punctures at and near anterior margin of pronotum larger (at least equal in diameter to 3 facets of an eye), at least one-third of them transversely elongate (each 2–4 times as wide as long); discal interstriae on basal one-third either smooth, with minute, simple punctures (no undulation or crenulation) or else closely, subacutely crenulate; antennal club longer than wide, its apex pointed 9
- 9(8). Pronotum minutely reticulate (80X); basal half of discal interstriae (weakly reticulate at 80X) essentially smooth, sparse minute, round punctures confused (no crenulations, calluses, or other elevations), posterior disc and declivity with widely spaced, uniseriate, subvulcanate pustules; male frons with subcrenulate rugae to upper level of eyes; Brazil (Nova Fribourg in Sao Paulo); 8.1–8.3 mm *mamillatus* Chapuis
- Pronotum smooth, shining (80X); discal interstriae minutely reticulate, with numerous, confused, subacute, transverse crenulations (transverse length of some crenulations equal to two-thirds width of an interstriae; frons broadly convex, smooth, shining from epistoma to vertex, with fine, shallow, round punctures; Brazil; 8.2–9.0 mm *ellipticus* Chapuis
- 10(1). Body 1.6–1.7 times as long as wide; eyes usually more widely separated above (1.8–3.6 times width of an eye); male frontal concave impression extending three-fourths distance from epistoma to upper level of eyes or to well above eyes; female pronotum unarmed by crenulations in 2 species (*punctatorugosus*, *nitidicollis*), crenulations present in males of all species 11
- Body more slender, 1.8–2.0 times as long as wide; eyes usually more narrowly separated above by 1.0 times width of an eye (except 2.0–2.5 in 3 species); male frontal impression more irregular, not always concave, restricted to about lower half of area below upper level of eyes 15
- 11(10). Male frons rather shallowly impressed on lower two-thirds of area below upper level of eyes; declivital tubercles absent or nearly so on interstriae 1–3; male pronotum mostly reticulate, with abundant, small asperities, female pronotum smooth, entirely devoid of asperities 12
- Male frons strongly impressed to upper level of eyes; declivital interstriae 1–3 tuberculate or crenulate to apex 13
- 12(11). Male frons more strongly, more broadly impressed, with tubercles extending well above eyes, pronotal asperities larger, extending to middle of pronotum, anterolateral angles much more prominently produced; female frons more strongly convex, particularly on middle half, punctures slightly larger; convexity from male and female upper frons to vertex gradual, uniform; surface of

- pronotum mostly smooth, shining, less reticulation seen only with greater magnification (80X); crenulations on posterior half of pronotum narrower, each less than one-third width of an interstriae, reticulate to their summits, fewer tubercles on lower half of declivity; Mexico (Veracruz) to Colombia; 4.6–8.1 mm *punctatorugosus* Chapuis
- Male frons much less strongly, less extensively impressed, tubercles less numerous, more rounded, ending above at upper level of eyes; anterolateral angles of pronotum much less strongly produced, smaller, sparse asperities confined to less than anterior one-third of pronotum; female frons more broadly convex, particularly on lower half, punctures slightly smaller; convexity on female frons on definite line between upper frons and vertex conspicuously more strongly, more abruptly convex; most of pronotum obscurely reticulate, seen with less magnification (40X); crenulations on posterior half of pronotum broader, most one-half as wide as an interstriae, their apical half (or more) smooth, brightly shining, slightly more tubercles on lower half of declivity; French Guyane to Brazil; 7.0–7.2 mm *nitidicollis* Chapuis
- 13(11). Male frons with margins of impressed area acutely elevated on upper one-third and lower one-fourth; interstitial crenulations wider, uniseriate, more widely spaced; Panama; 5.2 mm *minusculus* Wood
- Male frons with lateral crests of impressed area subacute to acute, lower half of impressed area with an acutely elevated median carina; interstitial crenulations on disc small, close, confused, occasionally uniseriate on declivity 1–3, surfaces rather coarsely reticulate 14
- 14(13). Male frons rather strongly impressed to slightly above level of eyes, a slight elevation on floor of impressed area near middle, median carina more strongly elevated on its dorsal one third, lateral crests not as high, summit more obtuse; pronotum more narrowly convex; elytral striae slightly wider, less abruptly impressed, interstriae more strongly convex, crenulations larger, transversely longer on disc and declivity; Mexico (Veracruz) to Brazil; 5.6–9.0 mm *asper* Erichson
- Male frons much more strongly impressed well above upper level of eyes, floor of concavity deeper, without a distinct elevation near middle, upper third of median carina less strongly elevated, lateral crests higher, more acute, a cluster of rather long setae on median surface near lower area; pronotum more broadly convex; elytral striae narrower, more abruptly impressed, interstriae weakly convex, crenulations lower, most less than one-fourth as wide as an interstriae; French Guyane to Brazil (Goias); 5.5–7.1 mm *ovatus* Eggers
- 15(10). Eyes more widely spaced above (2.0–2.5 times width of an eye); female frontal carina very short, often obscure (extending from epistoma to level of antennal insertion); pronotum with asperities restricted to anterior half or at least anterior from discal area 16
- Eyes more narrowly spaced above (less than 1.0 times width of an eye); median female frontal carina extending well above middle of area below upper level of eyes; pronotum with asperities on disc extending to base 20
- 16(15). Pronotal asperities confined to anterior half (including median area), posterior half closely, coarsely punctured (including lateral areas), spaces between punctures smooth, shining; discal striae wider; punctures distinct, interstitial crenulations more numerous, confused, forming close, uniseriate rows of pointed tubercles on declivity; elytra without any reticulation; Venezuela; 6.5 mm *marahuaci* Wood
- Pronotal disc punctured to base, crenulations in lateral areas extending to base, surface reticulate (except shining and finely punctured in *niger*), asperities mostly absent on median half from anterior to posterior margins 17
- 17(16). Asperities absent on median half of pronotum from anterior to posterior margin, punctures rather small, shallow, widely spaced, surface between punctures smooth, shining, asperities in lateral areas mostly small, except anterolateral angles each armed by 3–4 coarse asperities; discal striae more narrowly, deeply impressed, punctures obscure, strongly transverse interstitial crenulations less numerous, poorly formed tubercles on declivity much less numerous; color black; elytra with obscure reticulation at 40X; Costa Rica; 7.6 mm *niger* Wood

- Anterior part of pronotum (female only?) with a median groove (asperities absent at and near groove), a smooth, shining median line on basal one-fourth; surface of pronotum and elytra reticulate; larger, more slender species 18
- 18(17). Median groove on pronotum longer, occupying anterior one-fourth of pronotum length; interstitial setae short, stout, abundant, conspicuous; Guatemala; 9.0 *opacithorax* Schedl
- Median groove on female pronotum shorter, limited to anterior one-eighth of pronotum length (not evident in male); interstitial setae short, stout, sparse, inconspicuous 19
- 19(18). Median line of pronotum punctured on basal third; declivital interstriae 2 with a row of fine tubercles to apex; Peru; 7.3 mm *irregularis* Eggers
- Median line of pronotum without punctures on basal third; declivital interstriae 2 without tubercles; Colombia; 9.0–10.5 mm *grossus* Chapuis
- 20(15). Crenulations and asperities on pronotum weak, restricted to anterior half, punctured on posterior half 21
- Crenulations on pronotum continue to base at least in lateral areas, larger and closer 22
- 21(20). Female frons much more strongly impressed on lower half, median carina extending one half distance from epistoma to upper level of eyes; punctures on disc of pronotum subcircular, never confluent, their interiors reticulate; declivital interstriae 2 not impressed, tubercles continue to apex; color dark brown; Venezuela; 9.4–11.0 mm *orinocensis* Wood
- Female frons weakly impressed on lower half, median carina extending from epistoma to upper level of eyes; punctures on disc of pronotum mostly of irregular shape, at least half of them confluent, their interiors mostly smooth; declivital interstriae 2 modestly impressed, punctures absent on lower half; color reddish brown; Nicaragua; 7.5 mm *belti* Blandford
- 22(20). Crenulations on interstriae 2 and 4 on disc confused, strongly transverse, subacutely elevated; interstitial tubercles on declivity averaging smaller; Mexico (Veracruz) and Jamaica to Bolivia and Brazil; 7.3–9.2 mm *scaber* Erichson
- Crenulations on interstriae 2 and 4 uniseriate on at least posterior half of disc 23
- 23(22). Elytral disc obscurely reticulate, declivity weakly, distinctly reticulate; epistomal area weakly impressed; pronotum much more finely sculptured, crenulations low especially on basal half; tubercles on disc rather narrow, moderately high, acute, confused only near base of disc except on 3; Venezuela; at MV light; 10.4 mm *araguensis* Wood
- Elytral surface strongly reticulate on disc and declivity; epistomal area more strongly impressed; pronotum more coarsely sculptured, crenulations rather coarse to base; interstitial crenulations on disc from dorsal aspect each appearing one-fourth spherical in female, hemispherical in male, shining, confused at least on basal half; Colombia and Venezuela to Peru; 7.9–10.3 mm *cristatus* Chapuis

Phloeoborus signatus Strohmeyer
Plate III

Phloeoborus similis Eggers, 1942:272. Lectotype; Goyaz, Brazil; USNM, Washington, designated by Anderson & Anderson 1971:30 (References in Wood & Bright c1992:101)

Phloeoborus signatus Strohmeyer, 1909:248. Holotype; Jatahy, Brazil; DEI, Munchenberg (References in Wood & Bright c1992:101)
Phloeoborus bodei Eggers, 1930:164. Lectotype; Bolivia; USNM, Washington, designated by Anderson & Anderson 1970:6 (References and synonymy in Wood & Bright c1992:98). *New synonymy*
Phloeoborus guayanensis Eggers, 1942:268. Holotype; French Guyane; NHMW, Wien (References in Wood & Bright c1992:97). *New synonymy*

Diagnosis: Pronotal asperities absent; interstitial crenulations on disc less numerous, smaller, their crests rounded, accompanying punctures with minute setae (absent in rudis Erichson); area at base of declivity between crest of interstriae 9 and costal margin with two rows of punctures.

Male: Similar to female except smaller; impressed area of frons more distinct, dorsolateral margins slightly higher.

Female: Length 8.0–10.0 mm (male 7.0–8.3 mm), 1.9 times as long as wide; color very dark reddish brown; vestiture of very minute interstitial setae, each shorter than diameter of its puncture. Frons similar to rudis, except eyes separated above by half to full width of an eye. Pronotum and elytra similar to rudis, except for the following: striae punctures slightly larger; interstriae more convex, with crenulations less numerous and more nearly (but not) uniseriate, crests of crenulations not acute, most almost rounded, punctures at posterior face of crenulations usually with a minute bristle (shorter in length than diameter of its puncture); area between apex of interstriae 5 and crest of 9 more convex (not impressed); at base of declivity between costal margin and crest of interstriae 9 with two rows of punctures.

Distribution: Costa Rica to Argentina.

Costa Rica: 3 km SE Rio Naranjo, Guanacaste, 1-4-IV-1995, F.O. Parker (new record for Central America).

Argentina: Misiones Iguazu, 30-I-13-III-1945, Hayward-Wilink-Golbach.

Bolivia: Loma Alta, 23-XI-1956, G. Pinckert.

Brazil: Jatai in Goias; Minas, Seratao de Diamantina, Faz. das Melancias, 11-X-1902, E. Gounella; Santa Catarina.

Paraguay: Bernardino, K. Fiebrig.

Peru: Santi Beni, Dep. Junin, 18-IX-1935, 840 m, F. Woytkowski.

Notes: This report is based on the male holotype of *signatus* Strohmeier, on 1 male from Argentina, on 3 males from Bolivia, on 7 males and 7 females from Brazil (including 1 cotype), on 1 male and 2 females from Paraguay, and on 1 male and 1 female from Peru. I compared 2 males to the lectotype of *bodei* Eggers.

Phloeoborus willei Wood, n. sp.

Phloeoborus willei Wood: Holotype ♀; 6 km S San Vito, Puntarenas, Costa Rica; USNM, Washington, designated below

Diagnosis: Distinguished from *signatus* Strohmeier by the low, much weaker median carina on the female frons; by the less numerous, isolated, higher, narrower crenulations on the interstriae; and by the fine, weak reticulation uniformly distributed on the disc and declivity.

Female: Length 7.8 mm, 1.8 times as long as wide; color dark reddish brown. Frons less strongly, less extensively impressed than in *signatus*, a few weak punctures on upper third, median carina very weak, weakly acute; eye much narrower than in *signatus*, separated above by three fourths width of an eye; antennal club less strongly flattened, sutures more distinctly impressed, and micropubescence much less abundant than in other members of this genus. Pronotum 0.7 times as long as wide, outline from dorsal aspect obscurely subquadrate, transverse impression on anterior fourth more distinct

than in *signatus*, spaces between punctures less smooth. Elytra 1.4 times as long as wide, 2.2 times as long as pronotum; anterior margin of each elytron with about seven separate, small crenulations between bases of interstriae 2 and 5 (a weak non-crenulate costa in *signatus*); striae shallowly impressed on basal two-thirds of disc, punctures moderately large, rather shallow, interstriae two to almost four times as wide as striae, surface weakly, very finely reticulate, crenulations modestly confused, smooth, shining, moderately high, less than twice as wide as thick, crest narrowly rounded, posterior face on 1–4 on posterior half of disc each bearing a minute, slender seta. Declivity steep, broadly convex; sculpture with apex of interstriae 4–5 weakly elevated, then a weak impression from this summit to interstriae 9; crenulations smaller than on disc.

Distribution: Costa Rica.

Type material: The female holotype was taken 6 km S San Vito, Puntarenas Prov., Costa Rica, 19-21-III-1967, O.T.S. Course. The holotype is in the U.S. National Museum, Washington.

Phloeoborus intermedius Eggers

Phloeoborus intermedius Eggers, 1930:165. Holotype ♂; Guiana; NHMW, Wien (References in Wood & Bright c1992:99)

Diagnosis: Size, color, and body proportions as in *signatus* Strohmeier; differing from *signatus* by the more nearly crenulate interstitial tubercles (with their posterior faces usually vertical); by the strongly reticulate declivity on both striae and interstriae, reticulation continuing to base of disc at least in the interiors of interstitial punctures.

Male: Length 6.6 mm, 1.8 times as long as wide; color brown. Frons with sculpture as in *signatus*, vestiture more slender, distinctly longer. Pronotum about as in *signatus*, except interiors of punctures reticulate. Elytra similar to *signatus*, except posterior face of each subacute crenulation vertical (crenulations not as high or as sharp as in *rudis*); reticulation on basal one-third of disc confined to interiors of interstitial punctures, gradually spreading until at base of declivity entire interstriae and striae covered by reticulation. Declivital interstriae less strongly convex than in *signatus*, striae and interstriae continuously, strongly reticulate.

Distribution: Guiana: "Guiana."

Notes: The above treatment was based on the male holotype of *Phloeoborus intermedius* Eggers.

Phloeoborus rudis Erichson

Plate III

Phloeoborus rudis Erichson, 1836:55. Lectotype ♀; Brazil; MNB, Berlin, designated by Wood 1982:127 (Synonymy and references in Wood & Bright c1992:100)

Phloeoborus elongatus Chapuis, 1869:13. Holotype ♂; Brazil; IRSNB, Brussels

Phloeoborus rugipennis Eggers, 1942:271. Holotype ♀; San Salvador, Costa Rica; USNM, Washington

Diagnosis: Pronotal asperities absent; distinguished from *signatus* Strohmeier by presence of only one row of punctures at base of declivity between crest of interstriae 9 and costal margin; and by the much more acutely elevated interstitial crenulations.

Male: Similar to female except smaller; lower frons more strongly, more broadly impressed.

Female: Length 10.0–11.7 mm (male 6.4–9.0 mm), 1.8 times as long as wide; color very dark reddish brown to black. Frons below eyes more evenly, more strongly convex on upper half, shallowly impressed on less than lower half, an acutely elevated median carina (on lower one-third of area from epistoma to upper level of eyes) on impressed area; surface shining, punctures and vestiture obscure; eyes separated by a distance equal to width of 3 facets of eye. Pronotum 0.68 times as long as wide; anterolateral areas without asperities; surface smooth, shining except slight reticulation in anterior areas of some specimens; punctures rather large, deep, irregular but close in most areas; vestiture of a few minute bristles in anterior and lateral areas; propleura with a large mycetancium. Elytra 1.3 times as long as wide, 2.1 times as long as pronotum; striae impressed, punctures coarse, shallow; interstriae less than three times as wide as striae, feebly reticulate, crenulations moderately low, close, each one-fourth to two-thirds as wide as an interstriae, their crests acute; declivity convex, steep; vestiture restricted to a few short bristles, each about equal in length to diameter of a striae puncture.

Distribution: Belize to Argentina.

Argentina: Cited in Wood & Bright (c1992:100).

Brazil: Espirito Santo, 11-X-1920, No. 921, F. Hoffmann; Iguane, Sao Paulo, A.C. Brad; Mangaratiba, Rio de Janeiro, 19-XI-1914, R. Fischer; Roraima, Serra Grande, 11-20-X-1992, D.W. Davis; Val. du Rio Pardo, Sao Paulo, 12-1898, E. Gounelle; ys. Selviria, Fazenda, UNESP, 26-X-1989, *Psidium guajava* root, F. Movarao.

French Guyane: Cited in Wood & Bright (c1992:100).

Guiana: Cited in Wood & Bright (c1992:100).

Paraguay: "1932"; "K. Fiebrig."

Peru: Sani Beni in Junen, 18-IX-1935, 15-X-1935, F. Woytkowski.

Venezuela: 40 km E Canton, Barinas, 8-III-1970, 70 m, *Pouteria anibaefolia*, SLW; Campamento Rio Grande 30 km E Palmar, Barinas, 19-VI-1970, 200 m, *Licania densiflora*, SLW.

Hosts: *Licania densiflora*, *Pouteria anibaefolia*, *Psidium guajava*.

Biology: Monogynous, female apparently initiates the attack. On under side of large logs lying on the ground. One series in a root. New tunnels observed; oviposition had not started.

Notes: I examined 3 males and 6 females from Venezuela; 3 males and 25 females from Brazil; 2 males and 1 female from Paraguay. I also compared 2 females to the lectotype of *rudis* and 1 to the holotype of *rugipennis* Eggers. The male holotype of *elongatus* Chapuis was examined and compared to my series

Phloeoborus freyi Schedl

Phloeoborus freyi Schedl, 1955:274. Holotype ♂; Rio de Janeiro, Brazil; Frey Museum, subsequently transferred to NHMBS, Basel, Switzerland (References in Wood & Bright c1992:99)

Diagnosis: Distinguished from *rudis* Erichson by the distinctly smaller striae punctures on the disc, these punctures are separated within a row on the disc by low, transverse, subacutely elevated partitions; interstitial crenulations wider, higher, and punctures behind crenulations more obscure, often obsolete.

Male: Length 8.3–8.5 mm, 1.9 times as long as wide; color dark brown, almost black. Frons as in male *rudis*. Pronotum about as in *rudis*. Elytra 1.4 times as long as wide, 2.4 times as long as pronotum; striae rather strongly, narrowly impressed, punctures small, impressed; interstriae slightly more than twice as wide as striae, convex, obscurely reticulate in some areas, most crenulations half as wide as an interstriae, acute, subvertical behind, punctures often present, most obscure to obsolete. Declivity resembling *rudis*, except interstriae 9 from junction with 10 to middle of declivity much more narrowly, evenly costate, less acute to interstriae 1; punctures on crest of all interstriae much smaller, crests of rugae narrower, more acute, more consistently present.

Distribution: Brazil: Rio de Janeiro (Schedl 1955:274); Pau d'Alho itu, Sao Paulo, 15-XI-1960, U. Martins; Hansa Humboldt, Santa Catarina (Reitter paratype).

Notes: The above treatment was based on the Schedl paratype of *Phloeoborus freyi* Schedl at NHMW, Wien.

Phloeoborus procerus (Erichson)

Plate II

Phloeoborus procerus (Erichson), 1836:54 (*Phloeotrupes*). Holotype ♀; Brazil: MNB, Berlin (Synonymy and references in Wood & Bright c1992:99)

Phloeoborus sipolisii Fairmaire, 1887:16. Holotype, sex?; Minas-Geraes, Brazil; MNHN, Paris

Diagnosis: Pronotum unarmed by asperities; eyes above separated by twice width of an eye; frontal carina extending to upper level of eyes.

Female: Length 8.8–9.6 mm, 1.9 times as long as wide; color black. Frons similar to *rudis* Erichson except eyes separated above by twice width of an eye; convex, epistoma broadly, shallowly emarginate, surface coarsely, rather deeply punctured, median carina acutely elevated from epistoma to upper level of eyes; vestiture hairlike, sparse, moderately long below, inconspicuous. Pronotum 0.70 times as long as wide; without any asperities or other irregularities, surface smooth, brightly shining, punctures coarse, deep, spaced by 1–3 diameters of a puncture; glabrous. Elytra with striae narrowly, moderately impressed, punctures obscure; interstriae about three times as wide as striae, smooth, shining, crenulations mostly two-thirds as wide as an interstriae, somewhat uniseriate, their summit abrupt but not acute, punctures on their posterior slope not evident;

glabrous; declivity broadly, evenly convex; interstitial tubercles narrower, more widely spaced.

Distribution: Brazil: Encruzilhada, Bahia, XI-1972, 960 m, M. Alverenga; Ubatula, Sao Paulo, 22-X-1964, Moses 25392.

Notes: The above treatment was based on the female holotype of *Phloeotrupes procerus* Erichson and on 2 other females from Brazil.

Phloeoborus grandis (Erichson)

Plate II

Phloeoborus grandis (Erichson), 1836:54 (*Phloeotrupes*). Syntypes, 2 ♀♀; Brazil; MNB, Berlin (References in Wood & Bright c1992:99)

Phloeotrupes punctatus Schedl, 1976:64. Holotype ♀; Santo Leopoldina, Espirito Santo, Brazil; NHMW, Wien (References in Wood & Bright c1992:100). *New synonymy*

Diagnosis: Distinguished by the smooth, shining pronotum with very minute punctures; by the almost non-existent interstitial crenulations; and by the large, stout body form.

Male: As in female except frons more strongly impressed; pronotum with punctures much smaller, propleural fovea absent; interstitial elevations smaller.

Female: Length 7.9–12.5 mm, 1.7 times as long as wide; color black. Frons with upper half of area below upper level of eyes convex, smooth, with sparse, fine punctures, lower area moderately impressed (broadly, somewhat flattened), median half of epistomal margin modestly emarginate, a median carina present (somewhat inflated at its middle in 1 specimen), surface weakly reticulate, rather finely, obscurely punctured. Antennal club slightly wider than long, apex broadly rounded. Pronotum 0.78 times as long as wide, subquadrate; surface smooth, shining, punctures sparse, minute, largest about equal in diameter to 1 facet of eye, glabrous; pleural areas reticulate. Elytra 1.1 times as long as wide, 1.7 times as long as pronotum; crenulations on basal margins very poorly developed, submarginal crenulations not evident; striae narrowly, rather deeply impressed, punctures small, obscure; interstriae two to three times as wide as striae, surface smooth, shining, transversely impressed at obscure punctures, areas between punctures rounded (not at all crenulate). Declivity convex, steep; striae and interstriae narrower than on disc, low, obscure tubercles evident. Glabrous.

Distribution: Brazil to Paraguay.

Brazil: "Brasil 48404" (syntypes); Espirito Santo, Fruhstorker; Rio de Janeiro, Felipe; Ypiranga, cap., Sao Paulo, 4-I-1933, 1612, F. Halik.

Paraguay: San Bernardino, W. Eisenlohr V.

Notes: The above treatment was based on 1 female from Paraguay and on 1 male and 7 females from Brazil (two were syntypes).

Phloeoborus mamillatus Chapuis

Phloeoborus mamillatus Chapuis, 1869:14. Holotype ♂; Nova Fribourg, Brazil; IRSNB, Brussels (References in Wood & Bright c1992:99)

Diagnosis: Distinguished from *grandis* (Erichson) by the smaller size; by the subcrenulate upper frons; by the larger, transversely elongate, anterior pronotal punctures; and by the very different sculpture of the discal interstriae.

Male: Length 8.1–8.3 mm, 1.6 times as long as wide; color black, essentially glabrous. Frons triangularly impressed on lower three-fifths of area below upper level of eyes, lower half of impressed area with a median carina; area from dorsal end of carina to upper level of eyes, rather closely, moderately crenulate, a few small punctures above, surface reticulate; a few fine, short, hairlike setae in impressed area. Antennal club longer than wide, apex pointed. Pronotum 0.70 times as long as wide; subquadrate, without any crenulations; surface finely reticulate (40X), punctures on basal half small (each equal to twice diameter of a facet of eye), those on anterior half distinctly larger and most transversely elongate (four or more times as wide as long, a few at anterior margin transversely confluent). Elytra 1.1 times as long as wide, 1.7 times as long as pronotum; striae narrowly, moderately impressed; interstriae four or more times as wide as striae, surface obscurely reticulate (40X), weakly convex on basal half of disc and without any impressions or crenulations, sparse, minute punctures present; interstriae on posterior half of disc with central row of low obscurely submammiform or subvulcanate isolated elevations form a row increasing in size to declivity, height of largest equal to less than one-fifth of an interstriae. Declivity broadly convex, steep; elevations end at base of declivity except two on lower one-fourth on 1, one on 3, 5 with several, 9 carinate to junction with 2. Glabrous.

Distribution: Brazil: "Bresil, Deyr."; "N. Fribg." [Nova Fribourg, Sao Paulo].

Notes: The first of 2 male specimens in the Chapuis Collection (IRSNB, Brussels) is here designated as the lectotype of *P. mamillatus* Chapuis. Both specimens were used to prepare the above treatment.

Phloeoborus ellipticus Chapuis

Phloeoborus ellipticus Chapuis, 1869:15. Lectotype ♀; Brazil; IRSNB, Brussels, present designation (References in Wood & Bright c1992:99)

Diagnosis: Distinguished from *mamillatus* Chapuis by the smooth, shining, punctured frons and pronotum; by the finely, closely crenulate discal interstriae; and by the larger striae punctures.

Female: Length 8.2–9.0 mm, 1.6 times as long as wide; color black, essentially glabrous. Frons broadly convex from level of antennal insertion to vertex, smooth except limited reticulation at vertex, punctures rather large, moderately deep, with no granules or crenulation; area from epistoma to level of antennal insertion distinctly impressed and divided by a short median carina; a few hairlike setae in impressed area; antennal club longer than wide, apex pointed. Pronotum 0.67 times as long as wide; somewhat triangular; surface smooth, shining (40X),

punctures rounded on disc, distinctly impressed, each about equal to twice diameter of a puncture, twice as large toward anterior margin, a few near anterior margin transversely elongate (mostly no more than twice as wide as long). Elytra 1.1 times as long as wide, 1.4 times as long as pronotum; striae moderately, rather narrowly impressed, punctures rather small, obscure; interstriae about three times as wide as striae, moderately convex, finely reticulate (40X), transverse crenulations low, confused, wide (most at least half as wide as an interstriae), rather close, minute confused punctures scattered among crenulations. Declivity broadly convex, steep; crenulations end uniseriately at or near base of declivity, lower half of declivity without crenulations or tubercles, minute punctures present; striae narrower and deeper than on disc; interstriae 9 carinate to junction with 3.

Distribution: Brazil: "Bresil, Deyr."

Notes: The above treatment was based on the 3 female syntypes in the Chapuis Collection. The first of these female syntypes is here designated as the lectotype of *Phloeoborus ellipticus* Chapuis.

Phloeoborus punctatorugosus Chapuis

Phloeoborus punctatorugosus Chapuis, 1869:14. Holotype ♂; Nouvelle Grenada (now Colombia); IRSNB, Brussels (Synonymy and references in Wood & Bright c1992:98–100)

Diagnosis: Sexually dimorphic; male with frons impressed, pronotum partly asperate, elytral crenulations larger, more widely spaced, mostly uniseriate; female frons convex, pronotum entirely without asperities, elytral crenulations smaller, closer, confused.

Male: Frons convex above, a rather shallow, triangular, concave impression extending from epistomal margin about three-fourths of distance to upper level of eyes; a weak median carina in impressed area; surface minutely reticulate, dull, area below eyes (except in concave area) bearing low, isolated, transversely elongate tubercles. Pronotum with anterior two-fifths finely asperate except anterolateral angles unarmed; posterior areas with shallow, poorly formed punctures. Elytra with interstitial tubercles not as high as in female but wider, mostly uniseriate, much less numerous, more widely spaced within a row.

Female: Length 4.6–8.1 mm, 1.6 times as long as wide; color very dark brown, almost black. Frons broadly convex, almost smooth, shining (feebly reticulate at 80X), lower fourth moderately, transversely impressed, with a weak median carina on middle half of impressed area; punctures deep, rather coarse, uniformly distributed; eyes separated above by four times width of an eye; glabrous, except a few hairlike setae near epistoma. Pronotum 0.68 times as long as wide, quadrate, without any asperities, surface smooth, shining, rather finely, deeply, somewhat closely punctured. Elytra 1.1 times as long as wide; striae narrowly, abruptly, not deeply impressed, punctures fine, distinct; interstriae four times as wide as striae, minutely reticulate, crenulations rather small, sub-

acute, each about one-third to one-half as wide as one interstriae, close and confused on basal third of disc on 2–5, becoming uniseriate by declivital base, punctures not evident; declivity broadly convex; lower two-thirds with interstriae devoid of punctures and tubercles, except each with one or two very small tubercles irregularly placed.

Distribution: Mexico (Veracruz) to "Colombia."

Colombia: Calarca, Caldes, IX-X-1956, 57-2754, F.L. Gallego.

Hosts: *Coffea arabica*, *Inga* sp., *Psidium guajava*.

Notes: The population from Mexico to Colombia appears to represent 1, uniform species. The population from French Guyane to southern Brazil, named *nitidicollis* Chapuis, does not appear to be conspecific, and for this reason it is removed from synonymy and treated as a distinct species. Examined were 55 specimens from Mexico (Veracruz) to Panama. At the time this species was named, Panama was part of Colombia. It is possible that the "Nouvelle Grenada" (=Colombia) type locality for this species was actually in what is now Panama. Subsequent collections that actually came from Colombia are cited above.

Phloeoborus nitidicollis Chapuis, n. status

Phloeoborus nitidicollis Chapuis, 1869:14. Lectotype ♀; Nova Fribourg, Rio de Janeiro, Brazil; IRSNB, Brussels (References in Wood & Bright c1992:100)

Phloeoborus brevisculus Chapuis, 1869:14. Holotype ♂; Cayenne, Suriname; IRSNB, Brussels (References in Wood & Bright c1992:100)

Diagnosis: Very closely allied, but distinguished from *punctatorugosus* Chapuis by the more broadly (weakly) convex female frons, with punctures slightly smaller and with transition from upper frons to vertex much more abruptly rounded; and by the less numerous, larger interstitial crenulations, each crenulation on posterior half smooth and brightly shining.

Male: Frons shallowly, rather broadly impressed on lower half, a few granules between eyes. Pronotum finely, sparsely asperate near anterior margin, sparse, rather small granules on anterior third; posterior two-thirds smooth, minutely reticulate, small punctures moderately close. Elytra with interstitial crenulations smaller and not as close as in *punctatorugosus*.

Female: Length 7.0–7.2 mm, 1.7 times as long as wide; dark reddish brown (fully mature?); elytra glabrous. Frons as in female *punctatorugosus*, except more broadly (less strongly) convex, more distinctly impressed on lower half; punctures averaging distinctly smaller; median carina longer (almost half as long as distance from epistoma to upper level of eyes; about one-third as long in *punctatorugosus*); transition from upper frons to vertex conspicuously more abruptly rounded on a definite line. Pronotum 0.70 times as long as wide; about as in *punctatorugosus*, except reticulation on disc clearly visible at 40X (visible at 80X in *punctatorugosus*), glabrous. Elytra 1.3 times as long as wide, 2.0 times as long as pronotum; as in *punctatorugosus*, except interstitial crenulations

slightly larger, less numerous, crenulation surface usually smooth and shining to their base (usually reticulate to summit in *punctatorugosus*); crenulations near base of declivity usually wider, those on lower two-thirds of declivity mostly smaller.

Distribution: French Guyane to southern Brazil.

Brazil: Nova Fribourg, Rio de Janeiro; Jatai in Goias.

French Guyane: Cayenne.

Notes: The above treatment was based on the 2 female syntypes of *Phloeoborus nitidicollis* Chapuis in the Chapuis collection and on the male holotype of *P. brevisculus* Chapuis.

Phloeoborus minusculus, Wood, n. sp.

Phloeoborus minusculus Wood: Holotype ♂; Barro Colorado Island, Canal Zone, Panama; USNM, Washington, designated below

Diagnosis: The very small size and unusual male frons distinguish this species.

Male: Length 5.2 mm, 1.9 times as long as wide; color dark reddish brown. Frons strongly concave from epistoma to slightly above upper level of eyes, eye to eye on upper half (eyes separated by twice width of an eye), impressed area much wider on lower half, lateral margins acutely elevated on lower fourth, then subacute to middle, acute on lower portion of upper half of impression; surface in impressed area reticulate, punctures not evident; vestiture sparse, short, hairlike. Pronotum 0.65 times as long as wide; obscurely subquadrate; anterolateral angles with 1 large and 2 smaller crenulations, anterior fourth with small, confused crenulations, anterior margin armed on median third by an irregular row of small serrations; posterior areas almost smooth, obscurely reticulate, punctures shallow, moderately close, somewhat irregular in shape. Elytra 2.3 times as long as pronotum, 1.3 times as long as wide; striae narrowly, rather deeply impressed, small punctures obscure; interstriae weakly convex, reticulate, about 4 times as wide as striae; acute crenulations half to two-thirds as wide as an interstriae, confused at base on 2–5, uniseriate elsewhere, spaced within row by half to full width of an interstriae, narrower and closer near declivity. Declivity broadly convex; interstriae narrower; crenulations reduced to small tubercles or absent, a puncture on lower slope of each; vestiture mostly obsolete, a few minute interstitial setae on declivity.

Distribution: Panama.

Type material: The male holotype was taken at Barro Colorado Island, in the Canal Zone, Panama, 17-I-1953. Presumably taken at light. The holotype is in the U.S. National Museum, Washington.

Phloeoborus asper Erichson

Phloeoborus asper Erichson, 1836:55. Holotype ♂; Brazil; MNB, Berlin (Synonymy and references in Wood & Bright c1992:98)

Phloeoborus imbricornis Eichhoff, 1868:148. Holotype ♂; Mexico; Hamburg Museum, lost

Phloeoborus rugatus Blandford, 1897:153. Lectotype ♀; Chontales, Nicaragua; BMNH, London

Diagnosis: Male frontal impression extended to upper level of eyes, pronotum more coarsely sculptured than *punctatorugosus* Chapuis, elytra reticulate and with crenulations more numerous.

Male: Length 5.9–7.9 mm. Similar to female except most slightly smaller; frons strongly impressed to well above eyes, lateral margins subacutely elevated on lower fourth, strongly elevated but rounded on middle half, median carina acute, strongly elevated on lower half.

Female: Length 5.6–9.0 mm, 1.6 times as long as wide; color black. Frons convex, reticulate; punctures of moderate size, close, rather deep; median carina strong, extending from epistoma more than half distance to upper level of eyes; a few hairlike setae on lower fourth; eyes separated by distance equal to twice width of an eye. Pronotum 0.73 times as long as wide; anterolateral angles elevated, each armed by three basally contiguous, coarse, crenulations; anterior half finely asperate; a row of basally contiguous asperities arm median half of anterior margin. Elytra 1.07 times as long as wide, 1.9 times as long as pronotum; striae narrowly, deeply impressed, punctures obscure; interstriae about four or more times as wide as interstriae, moderately convex, reticulate, crenulations acutely elevated, close, each one-third to one-half as wide as an interstriae, punctures on posterior slope of crenulations very small, each bearing a tiny, short bristle. Declivity convex; interstriae narrower; asperities reduced in size, rounded, most replaced by a coarse puncture.

Distribution: Mexico (Veracruz) to Brazil.

Brazil: "Brazil" (holotype of *asper*).

Venezuela: 40 km E Canton, Barinas, 8-III-1970, No. 400, *Protium tenuifolium*, No. 371, *Pouteria anibaefolia*, SLW; Campamento Rio Grande 30 km E Palmar, Bolivar SLW.

Notes: Examined were 24 specimens from Venezuela. The male holotype of *Phloeoborus imbricatus* Eichhoff was lost in 1944 with the Hamburg Museum. It had been previously placed in synonymy by Chapuis (1869:8) and Strohmeyer (1909:25). Their placement is accepted as correct. It is probable that *P. granosus* Eichhoff and *P. sulcifrons* Eichhoff, treated below, are also synonyms of this species.

Phloeoborus ovatus Chapuis, n. status

Phloeoborus ovatus Chapuis, 1869:15. Lectotype ♂; Cayenne, Suriname; IRSNB, Brussels, designated by Wood 1982:123 (References in Wood & Bright c1992:98)

Phloeoborus granulatus Eggers, 1943:243. Holotype ♂; French Guyane; DEI, Muncheberg (References in Wood & Bright c1992:99). *New synonymy*

Diagnosis: Very similar to *asper* Erichson but clearly distinguished by characters presented in the above key and in the following description.

Male: Length 5.5–7.1 mm, 1.6 times as long as wide; color black. Frons rather deeply, broadly concave from well above upper level of eyes (15 percent of its length above eyes, less than 10 percent in *asper*), concavity

deeper than in *asper*, without a significant elevation on floor at middle of concavity, upper half of median carina less strongly elevated, lateral convexities more abrupt, higher, crest more acute, with 6–10 long setae on lower end on mesal surface; lateral margin below level of antennal insertion more acutely elevated. Pronotum 0.66 times as long as wide, more broadly convex; sculpture resembling *asper*. Elytra 1.07 times as long as wide, 1.9 times as long as pronotum; striae narrowly, abruptly, rather deeply impressed, punctures obscure to obsolete; interstriae three times as wide as striae, weakly convex (much less convex than *asper*), strongly reticulate, crenulations shining, most one-fourth as wide as an interstriae, some up to one-third as wide as an interstriae, all acute but not high (much lower and narrower than in *asper*). Declivity steeper and more broadly convex than in *asper*; interstriae less strongly convex and crenulations smaller than in *asper*.

Distribution: French Guyane and Guiana to Brazil.

Brazil: Jatai in Goias.

French Guyane: "Cayenne, Deyr."

Guiana: Brit. Guiana, Bartica District, IV-1957, E.J. Duffy, BM 1957-394; Maroni.

Notes: The above treatment was based on the male lectotype of *ovatus* Chapuis, on 2 male paralectotypes, and on my male homotype of *ovatus*, which I compared directly to the holotype, on the holotype of *granulatus* Eggers, which was also compared to my homotype of *ovatus*, and on 1 male from Brazil. These names represent synonyms of one another. It is not a synonym of *asper* Erichson.

Phloeoborus marahuaci Wood, n. sp.

Phloeoborus marahuaci Wood: Holotype ♀; N slope, Mt. Marahuaca, Amazonas, Venezuela; USNM, Washington, designated below

Diagnosis: Distinguished by the small size and slender body form; by the absence of reticulation on the pronotum and elytra; and by the restriction of asperities to the anterior third of the pronotum.

Female: Length 6.5 mm, 1.9 times as long as wide; color dark brown. Frons convex above level of antennal insertion; moderately, transversely impressed below level of antennal insertion, an obscure median carina in impressed area; surface smooth, shining, punctures close, coarse, deep; obscure hairlike setae restricted to impressed area. Antennal club weakly flattened; 2 transverse sutures on basal half. Pronotum 0.73 times as long as wide; subquadrate; asperities small, rather numerous, restricted to slightly more than anterior one-third; posterior areas smooth, shining, rather coarsely, closely, deeply punctured; glabrous. Elytra 1.3 times as long as wide, 2.0 times as long as pronotum; striae moderately impressed, punctures rather small, distinct; interstriae about three times as wide as striae, surface smooth, shining, crenulations less than one-third as wide as interstriae, each crenulation moderately high, its posterior face about vertical, crenulations confused except uniseriate

on posterior half of 1 and 4. Declivity convex, steep; striae not impressed, punctures larger and deeper than on disc; interstriae smooth, shining, each with a uniseriate row of moderately large, subacute, closely set tubercles, slightly smaller below; interstriae 9 finely serrate (dorsal aspect) from middle of disc to apex. Vestiture of minute setae, each arising from posterior margin of crenulations.

Distribution: Venezuela (Amazonas)

Type material: The female holotype was taken at the Benitez Camp, N slope Mt. Marahuaca, Amazonas, Venezuela, 1-25 May 1950. The holotype is in the U.S. National Museum, Washington.

Phloeoborus niger Wood, n. sp.

Phloeoborus niger Wood: Holotype ♀; 3 km SE Rio Naranjo, Guanacaste, Costa Rica; USNM, Washington, designated below

Diagnosis: Distinguished by the rather widely spaced eyes; by the absence of asperities on the median half of the pronotum, but with about 3 coarse asperities on lateral areas; and by the distinctive sculpture of the elytra.

Female: Length 7.6 mm, 1.7 times as long as wide; color black, dorsal areas glabrous. Frons moderately convex on dorsal 80 percent of area below upper level of eyes, moderately, transversely impressed from epistomal margin to level of antennal insertion, impressed area with a short, low, subacute median carina on slightly more than lower 20 percent; upper convex areas shining, weakly reticulate below, reticulation stronger above eyes, punctures rather small, moderately close, glabrous except sparse hair on impressed area below. Pronotum 0.63 times as long as wide; median half (median one-third anteriorly) smooth, shining (at 40X) punctures small, shallow, spaced by 2–5 diameters of a puncture from anterior margin to base; lateral areas mostly finely asperate, except anterolateral angles each armed by 4 coarse asperities; glabrous except on basal margin. Elytra 1.2 times as long as wide, 2.0 times as long as pronotum; striae narrowly, abruptly impressed, punctures small, obscure; interstriae about 4 times as wide as striae, surface shining, obscurely reticulate at 40X, crenulations low, rather sparse except at base, a few up to half as wide as an interstriae, some represented by fine punctures. Declivity convex, steep; striae deeper than on disc, interstriae more strongly convex, poorly formed crenulations rather broad, closer than on disc. Glabrous.

Distribution: Costa Rica (Guanacaste).

Type material: The female holotype was taken 3 km SE Rio Naranjo, Guanacaste, Costa Rica, VII-1992, at light, F.D. Parker. The holotype is in the U.S. National Museum, Washington.

Phloeoborus irregularis Eggers

Phloeoborus irregularis Eggers, 1942:270. Holotype ♂; Peru; BMNH, London (References in Wood & Bright c1992:99)

Diagnosis: Distinguished from *grossus* Chapuis by the punctured median line on the basal third of the

pronotum; and by the presence of a row of small tubercles on declivital interstriae 2.

Male: Length 7.3 mm, 1.7 times as long as wide; color dark reddish brown. Frons broadly impressed near epistoma, continuing (rather strongly) on median half to two-thirds distance from epistoma to upper level of eyes, an obscure, feeble, median elevation indicated on lower and upper thirds; surface obscurely reticulate to vertex, punctures small to irregular; rather obscure; impressed area with fine, short, sparse, hairlike setae. Pronotum 0.63 times as long as wide; anterior one-fourth of median line distinctly, shallowly sulcate; crenulations low, obtuse (none large or acute); punctures rather small, deep, close, their interiors and general surface rather strongly reticulate, crests between punctures and low asperities smooth, shining, sparse, short, hairlike setae present. Elytra 1.3 times as long as wide, 2.3 times as long as pronotum; striae narrowly impressed, small punctures mostly obscure; interstriae two to three times as wide as striae, convex, surface strongly reticulate, crenulations close, rather high (summits narrowly rounded, never acute) each transverse crenulation about two-thirds as wide as an interstriae. Declivity broadly convex, steep; strial punctures much larger than on disc, distinctly impressed; interstitial tubercles uniseriate on upper third, almost to entirely obsolete below. Vestiture restricted to declivity, of sparse, minute, interstitial hair.

Distribution: Peru: "Peru."

Notes: The above treatment was based on the male holotype.

Phloeoborus grossus Chapuis

Phloeoborus grossus Chapuis, 1869:13. Lectotype ♀; Colombie; IRSNB, Brussels, present designation (References in Wood & Bright c1992:99)

Diagnosis: Distinguished from *opacithorax* Schedl by the much shorter median groove near the anterior margin of the female pronotum; and by the smaller, much less abundant, less conspicuous interstitial setae.

Male (?): Smaller; median sulcus near anterior margin of pronotum absent; interstitial tubercles on declivity smaller, present on 2 to its apex.

Female: Length 10.5 mm (male 9.0), 1.9 times as long as wide; color dark reddish brown, vestiture sparse, minute, inconspicuous. Frons with lower half of area below upper level of eyes transversely impressed and divided by a median carina; upper half reticulate, irregularly, rather coarsely punctured; sparse vestiture mostly restricted to impressed area; eyes separated above by 1.15 times width of an eye; area above eyes more strongly reticulate, sparse punctures moderately coarse, shallow; antennae missing from type (in male longer than wide, a bit asymmetrical, apex blunt). Pronotum 0.68 times as long as wide; asperities absent on central area (median one-fourth at anterior margin, expanding to median three-fifths at base), small, except somewhat larger at anterolateral angles; median line on anterior one-eighth mod-

erately sulcate, basal one-third with median line impunctate; surface reticulate, punctures moderately coarse, irregular in size, spacing, and outline, more widely spaced on basal half of disc; vestiture minute, sparse, almost hairlike. Elytra 1.4 times as long as wide, 2.2 times as long as pronotum; striae distinctly impressed, punctures small, distinctly impressed; interstriae rather weakly convex, strongly reticulate, punctures minute, confused, sparse, transverse crenulations low, subacutely elevated, confused at base, uniseriate before base of declivity, each up to half as wide as an interstriae at base, less than one third as wide at base of declivity. Declivity broadly convex, steep; striae slightly wider, interstriae narrower than on disc; interstriae 1–8 each with a sparse row of moderately coarse tubercles (absent on lower one-third of 2). Vestiture of sparse, very short, slender, inconspicuous setae.

Distribution: Colombia: "Colombie, Dejean."

Notes: The above treatment was based on the 2 syntypes in the Chapuis collection. The first of these syntypes, a female, is here designated as the lectotype of *Phloeoborus grossus* Chapuis. The second syntype, a lectoparatype, is thought to be a male.

Phloeoborus opacithorax Schedl, n. status

Phloeoborus opacithorax Schedl, 1940:205. Lectotype ♀; Panzos, Guatemala; DEI, Munchenberg, present designation (References in Wood & Bright c1992:101)

Diagnosis: Resembling *scaber* Erichson but distinguished by having the eyes separated by twice the width of an eye; by the short, stout, abundant yellow setae on the pronotum and elytra; by the narrower (transversely), much more numerous, more strongly confused interstitial crenulations; and by the stouter body form.

Female: Length 9.0 mm, 1.7 times as long as wide; color dark reddish brown, vestiture very short, abundant, pale yellow. Frons with eyes separated by distance equal to twice width of an eye; lower one-third transversely impressed, divided by a rather strongly elevated, acute carina (equal in length to one-third distance from epistoma to upper level of eyes); middle one-third moderately convex, with reticulate, impunctate median line distinctly impressed; lateral areas of lower two-thirds subshining, rather coarsely, irregularly, subrugosely punctured, with rather abundant, recumbent, fine and coarse, hairlike setae; area above upper level of eyes convex, reticulate, rather coarsely punctured. Pronotum 0.64 times as long as wide; subquadrate, anterolateral angles each with 4–5 rather coarse serrations, anterior one-third moderately, coarsely asperate, basal half more finely, closely asperate; areas between crenulations strongly reticulate; median line on anterior one-third moderately, rather narrowly sulcate, part of this groove without crenulations, its surface reticulate; basal one-third with broad median line smooth, shining, impunctate, 2 similar shining and impunctate areas in lateral areas at

middle of pronotum about half distance from median line to lateral margin; vestiture of conspicuous, short, stout, recumbent setae of moderate abundance. Elytra 1.25 times as long as wide, 2.2 times as long as pronotum; striae narrowly impressed, minute punctures obscure; interstriae about six times as wide as striae, surface rugose-reticulate between crenulations, crenulations narrow (mostly less than one-third as wide as an interstriae), close, confused, sharply elevated, their upper half smooth shining, each with a short, stout, yellow seta arising from its posterior slope (collectively these setae conspicuous). Declivity steep, convex; interstitial crenulations becoming mostly uniseriate and decrease in size posteriorly. Vestiture as described above.

Distribution: Guatemala: Panzos, Staudinger & Bang-Hass.

Notes: The female syntype at DEI, Muncheberg, is here designated as the lectotype of this species. Because occasional females of *scaber* resemble this species, it was placed in synonymy (Wood 1974:285); however, the larger, stouter body form, more widely spaced eyes, and the abundant, yellow vestiture suggest that it should be restored to full species status.

Phloeoborus orinocensis Wood, n. sp.

Phloeoborus orinocensis Wood: Holotype ♀; Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela; USNM, Washington, designated below

Diagnosis: Eyes separated above by less than half width of an eye; pronotum subquadrate, with very small asperities restricted to anterior fourth; elytra reticulate, crenulations small, abundant, confused.

Female: Length 9.4–11.0 mm, 1.8 times as long as wide; color almost black, a slight reddish brown cast. Frons convex above, modestly, transversely impressed on lower half, with an acute median carina in impressed area; surface above smooth, with moderately close, deep punctures, in impressed area surface irregular; punctures obscure; vestiture of sparse, short, inconspicuous hair. Pronotum 0.66 times as long as wide; subquadrate; crenulations small, restricted to anterior fourth, punctures gradually decreasing in rugosity toward middle (crenulations not larger on anterolateral angles); posterior area (including punctures) obscurely reticulate, punctures moderately coarse, close, oval, interspaces mostly equal to not more than half diameter of a puncture. Elytra 1.3 times as long as wide, 2.0 times as long as pronotum; striae moderately, narrowly impressed, punctures small, distinct; interstriae about four times as wide as striae, weakly convex, reticulate, crenulations acute, each one-fourth to one-third as wide as an interstriae, rather close, confused, shining. Declivity steep, broadly convex; crenulations on interstriae 1–3 reduced in size to tubercles and uniseriate, obsolete on lower third; vestiture consisting of minute bristles arising from puncture on posterior slope of each crenulation or tubercle from base

of elytra to apex, their length equal to less than diameter of a striae puncture.

Distribution: Venezuela (Bolivar).

Type material: The female holotype and 7 female paratypes were taken at Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela, 12-VI-1970, 200 m, No. 551, *Licania densifolia*, S.L. Wood. The holotype and paratypes are in the U.S. National Museum, Washington.

Phloeoborus belti Blandford

Phloeoborus belti Blandford, 1897:151. Holotype ♀; Chontales, Nicaragua; BMNH, London (References in Wood & Bright c1992:98)

Diagnosis: Distinguished from *orinocensis* Wood by the smaller size; by the long female frontal carina; by the largely confluent punctures on the basal half of the pronotum; and by the distinctly impressed declivital interstriae 2 on which tubercles are absent from the lower half.

Female: Length 7.5 mm, 1.7 times as long as wide; color reddish brown. Frons weakly impressed on lower two-thirds, a distinct median carina from epistoma to upper level of eyes. Pronotum 0.66 times as long as wide; surface smooth, shining; asperities on lateral fourths low, obtuse (none large or sharp); punctures deep, rather small, of irregular shape, about half of them confluent, their interior almost smooth; glabrous. Elytra 1.25 times as long as wide, 2.2 times as long as pronotum; striae rather deeply, narrowly impressed, punctures small, distinct; interstriae about three times as wide as striae, surface obscurely reticulate, mostly shining, crenulations on basal two-thirds of disc confused, rather high, each about one-third as wide as an interstriae, becoming narrower and uniseriate toward declivity. Declivity rather steep, convex; interstriae 2 weakly, distinctly impressed, devoid of tubercles on lower half, uniseriate tubercles on 1 and 3–9; surface more strongly reticulate than on disc. Vestiture limited to declivital interstriae, short, hair-like, sparse.

Distribution: Nicaragua: Chontales, T. Belt.

Notes: The above treatment was based on the female holotype.

Phloeoborus scaber Erichson

Phloeoborus scaber Erichson, 1869:13. Lectotype ♀; Bahia, Brazil; MNB, Berlin, designated by Wood 1982:126 (Synonymy and references in Wood & Bright c1992:98–99)

Phloeotrupes caelatus Blanchard, 1846:204. Syntypes, sex?; Bolivia; MNHN, Paris

Phloeoborus sericeus Chapuis, 1869:13. Lectotype ♂; Cayenne; IRSNB, Brussels, designated by Wood 1982:126

Phloeoborus lumatulus Eggers, 1943:242. Lectotype ♀; Brazil; USNM, Washington, designated by Anderson & Anderson 1971:18 (References in Wood & Bright c1992:99). *New synonymy*

Diagnosis: Pronotal crenulations extend to base, larger; interstitial crenulations on disc more numerous, confused, transversely elongate, neither hemispherical nor one-fourth spherical (as seen from dorsal aspect).

Male: Similar to female except smaller; frons impressed more extensively than in *cristatus* Chapuis, with lateral areas less strongly elevated.

Female: Length 7.3–9.2 mm (male 6.3–7.5 mm), 1.7 times as long as wide; color dark reddish brown. Frons about as in *cristatus*, except upper half rugose, punctures obscure. Pronotum similar to *cristatus*, except asperities larger, more numerous, anterolateral angles more prominent, their crenulations much larger. Elytra 1.2 times as long as wide, 2.1 times as long as pronotum; similar to *cristatus*, except interstitial crenulations wider, half to two-thirds as wide as an interstriae, their main axis transverse (not one-fourth or half of a sphere); declivity similar to *cristatus*, except interstitial tubercles smaller.

Distribution: Mexico and Jamaica to Peru and Brazil.

Jamaica: Bonnie View, Port Antonio, 25-VII-1952, at light, A.M. Laessle (New record).

Bolivia: "Bolivia."

Brazil: Espirito Santo, 11-X-1920, No. 921, F. Hoffmann; Iguane, Sao Paulo, A.O. Brada; Jatai in Goias; Rondonia 62 km SE Ariquemes, 7-18-XI-1995, W.J. Hanson; Bahia; Santa Catarina.

French Guyane: "Cayenne."

Guiana: 1929, W. Robinson.

Venezuela: 8 km SW Bumbum, Barinas, 11-II-1970, 150 m, No. 319, *Ficus*, SLW; 40 km E Canton, Barinas, 3-III-1970, 70 m, No. 400, *Protium tenuifolium*, SLW; 10 km SE Miri, Barinas, 8 II-1970, 150 m, No. 304, *Brosimum*, SLW.

Trinidad: Simia, 1–15 July 1962, J. Maldonado C. (New record).

Hosts: *Brosimum* sp., *Ficus* sp., *Protium tenuifolium*.

Notes: The above treatment was based on 48 specimens; I compared 1 of these females to the holotype of *scaber* Erichson, 1 male to the holotype of *sericeus* Chapuis, and 1 female to the female lectotype of *lunatulus* Eggers. The "male holotype" and 11 paratypes of *lunatulus* were also examined. This "male holotype" (syntype) is here designated as the lectoallotype of *lunatulus* Eggers.

Phloeoborus araguensis Wood, n. sp.

Phloeoborus araguensis Wood: Holotype ♀; Rancho Grande, Aragua, Venezuela; USNM, Washington, designated below

Diagnosis: Eyes separated above by distance equal to width of an eye, an acutely elevated carina on lower half of area below eyes; asperities on pronotum poorly formed, punctures indistinct; interstitial crenulations mostly uniseriate, punctures not evident; lower declivity with some reticulation.

Female: Length 10.4 mm, 1.9 times as long as wide; color black, with a slight reddish brown cast (not fully mature?). Frons moderately convex, surface obscure, an acutely elevated median carina on slightly more than lower half. Pronotum 0.70 times as long as wide, somewhat subquadrate in outline; asperities small, poorly

formed, numerous on anterior half, rugosities continuing on median third to base; punctures in lateral areas obscure. Elytra with striae narrowly, moderately impressed, punctures small, distinct; convex, interstriae about five times as wide as striae, moderately convex, crenulations small, subacute, each about one-third as wide as interstriae, moderately confused on 3 and 4 on disc, all smaller and uniseriate on declivity; declivity broadly convex, all interstriae about equally convex, tubercles of moderate size, uniseriate; surface finely reticulate except shining tubercles; glabrous, except most tubercles on declivity bearing a very short, stout, inconspicuous bristle.

Distribution: Venezuela (Aragua).

Type material: The female holotype was taken at Rancho Grande, Aragua, Venezuela, 9-IV 1970, No. 402, at mercury vapor light, SLW. The holotype is in the U.S. National Museum, Washington.

Phloeoborus cristatus Chapuis

Phloeoborus cristatus Chapuis, 1869:13. Holotype ♂; Bogota, Colombia; IRSNB, Brussels (Synonymy and references in Wood & Bright c1992:98–99)

Phloeoborus radulosus Blandford, 1897:153. Syntypes, sex?; Ecuador; BMNH, London, Fry Collection at Basel, and Schaufuss Collection
Phloeoborus aspericollis Strohmeier, 1909:248. Holotype ♂; Llanos, Ecuador; DEI, Munchenberg (Synonymy and references in Wood & Bright c1992:98). *New synonymy*

Diagnosis: Pronotal crenulations extend to base; interstitial crenulations on disc much more numerous, apparently forming one-fourth of a sphere in female, hemispherical and less numerous in male.

Male: Similar to female except smaller; frontal impression extending almost to eyes, lateral margins much more strongly elevated above level of antennal insertion; crenulations on discal interstriae hemispherical, less numerous.

Female: Length 10.3 mm (male 7.9–8.3 mm), 1.8 times as long as wide; color black, with a slight reddish brown cast. Frons convex above, moderately, transversely impressed on lower fourth, impressed area with an acutely elevated rather strong, median carina; surface reticulate, coarsely, closely punctured above, punctures obscure in impressed area; vestiture sparse, short, hairlike; eyes separated above by a distance equal to slightly more than half width of an eye. Pronotum 0.66 times as long as wide, subquadrate; surface reticulate, asperate to base, asperities slightly larger on anterior half, punctures accompany some rugae on posterior half of disc; asperities not larger at anterolateral angles. Elytra 1.3 times as long as wide, 2.1 times as long as pronotum; striae rather weakly impressed, punctures moderately large, deep; interstriae weakly convex, about three times as wide as striae; surface strongly reticulate, crenulations acute, smooth, shining, each appearing to form one-fourth of a sphere, one-third to half as wide as an interstriae, close, confused, their posterior slope subvertical, with puncture often visible. Declivity convex, steep;

interstriae narrower, crenulations narrower and uniseriate, largely absent on lower third; vestiture of minute bristles at posterior margin of most crenulations and tubercles.

Distribution: Colombia and Venezuela to Brazil and Peru.

Brazil: "Brasilien."

Colombia: Bogota.

Ecuador: "Llanos."

Peru: Chanchamyo [River].

Venezuela: Rancho Grande, Aragua, 14-II-1969, blacklight, P. & P. Spangler, and 9-IV 1970, 1100 m, log, SLW.

Notes: The above treatment was based on 5 males and 1 female. The male holotype of *Phloeoborus cristatus* Chapuis was examined and compared by me to the other 4 males. These 5 specimens were also compared to the holotype of *P. aspericollis* Strohmeyer. I also compared to this type 1 male from Brazil and 1 from Peru; other males were unlabeled. Eggers (1929:53) cites *radulosus* Blandford as a synonym. He also placed *Phloeoborus aspericollis* Strohmeyer in synonymy with this species (Eggers 1943:241).

Species Not Seen

Phloeoborus gaujonii Fairmaire

Phloeoborus gaujonii Fairmaire, 1887:16. Holotype, sex?; Loja, Equateur; MNHN, Paris, not found (References in Wood & Bright c1992:99)

Holotype: Length 9 mm, black in color; near *asper* and *ovatus*; eyes approximate; frons with an obtuse median carina.

Notes: The type of *Phloeoborus gaujonii* Fairmaire should be in the Paris Museum; however, an effort to locate it was not successful. The probability is high that it is a synonym of either *asper* or *ovatus*. The above notes were gleaned from the original description of the type (Fairmaire 1887:16).

Phloeoborus granosus Eichhoff

Phloeoborus granosus Eichhoff, 1868:148. Holotype ♀ ♂?; Brazil; Hamburg Museum, lost (References in Wood & Bright c1992:99)

The original description of the holotype of *Phloeoborus granosus* Eichhoff is quoted from Eichhoff (1868:148) as follows:

"Subcylindricus, piceus, sericeo-nitens, fronte punctata convexa, rostro carinato, utrinque leviter impresso; thorace rugolis creberrimis tuberculisque levis scabro; elytris cylindricus subtiliter punctato-striatus, interstitiis planis tuberculisque subtransversis apice subseriatus crebre rugosis. Long. 4 line (about 9 mm)—Patr.: Brasilia."

Notes: This description could apply to several known Brazilian species. The type is presumed to have been lost with the Eichhoff collection in the Hamburg Museum. Before the type was lost, Eggers (1942:166) associated it with *asper* Erichson. Because the species is not identifiable, due to the loss of the unique type, I consider it to be a probable synonym of *asper* Erichson.

Phloeoborus sulcifrons Eichhoff

Phloeoborus sulcifrons Eichhoff, 1868:148. Holotype ♂; Brazil; Hamburg Museum, lost (References in Wood & Bright c1992:101)

The original description of the male holotype of *Phloeoborus sulcifrons* Eichhoff is quoted from Eichhoff (1868:148) as follows:

"Ovalis, convexus, piceus subnitidus, fronte profunde excavata, rostro medio argute, carinato utrinque profunde impresso; rugoso antice utriusque subimpresso, tuberculatoque, puncto utrinque discoidali laevi, basi medio impressa carinulata; elytris striatis, interstitiis planis creberrime rugoso-scabris—Long. 3 1/2 lin.—Patr. Brasilia int. (Mus. Dr. Haag)."

Eggers associated this type with *asper*. Without a type this species is unidentifiable. I consider it to be a probable synonym of *Phloeoborus asper* Erichson.

TRIBE TOMICINI

Frons weakly to moderately sexually dimorphic, male usually impressed, female usually convex; eye oval to ovate, entire; antennal scape elongate, funicle 5- to 7-segmented, club symmetrical, weakly to moderately flattened, usually with three or four sutures; pronotum unarmed by asperities (rare exceptions in some *Xylechinosomus* and *Xylechinus*); procoxae contiguous to narrowly separated, precoxal carinate costa absent; sutural groove on mesal surface of elytra continued to base without interlocking nodules and cavities; tibiae armed on lateral and apical margins by socketed teeth.

Biology: All species are monogynous; all are phloeophagous (except *Hylurgonotus*?). Parental galleries are biramous, except monoramous in *Dendroctonus*, *Hylurgus*, and some *Tomicus*. Those of *Sinophloeus* and *Hylurgonotus* are unknown. Eggs are placed in niches and packed individually in frass, except some *Dendroctonus* may place many eggs together in long grooves. Larval mines usually show on the surface of peeled bark. Symbiotic relationships with fungi are important in most genera as a means of overcoming host resistance to attack, not as a primary food source.

Key to the Genera of Tomicini

- | | | |
|-------|--|-----------------------|
| 1. | Metepisternal setae scalelike or plumose; antennal funicle 7-segmented | 2 |
| — | Metepisternal setae except <i>Xylechinus</i> (bifid in one <i>Hylurgonotus</i> having a 7-segmented funicle); antennal funicle 5- to 7-segmented | 3 |
| 2(1). | Anterolateral areas of pronotum often asperate; male frons moderately to strongly impressed; host <i>Araucaria</i> ; 1.3–3.4 mm scutellum, visible, large | <i>Xylechinosomus</i> |
| — | Anterolateral areas of pronotum unarmed; frons concavely impressed in both sexes and with a strongly developed, subacute, median carina; scutellum not visible, host <i>Araucaria</i> ; 2.4–3.1 mm | <i>Sinophloeus</i> |
| 3(1). | Ground vestiture on elytra scalelike; antennal funicle 5-segmented; median, frontal carina present or not; procoxae rather widely separated; coniferous and broadleaf hosts; 1.5–3.5 mm | <i>Xylechinus</i> |
| — | Ground vestiture on elytral disc hairlike, metepisternal setae hairlike except bifid in one <i>Hylurgonotus</i> (but funicle 7-segmented) | 4 |
| 4(3). | Protibiae armed on distal and lateral margins by 3 or 4 socketed teeth; male frons feebly to strongly impressed; antennal funicle 7-segmented; host <i>Araucaria</i> ; 2.7–4.6 mm | <i>Hylurgonotus</i> |
| — | Protibiae armed on distal and lateral margins by 5 or more socketed teeth; antennal funicle 5- or 6-segmented; male frons convex; introduced species in Pinaceae | 5 |
| 5(4). | Antennal funicle 5-segmented, club moderately flat with sutures at least slightly procurved; procoxae contiguous; hosts <i>Pinus</i> , <i>Picea</i> , <i>Pseudotsuga</i> | <i>Dendroctonus</i> |
| — | Antennal funicle 6-segmented, club conical, sutures straight | 6 |
| 6(5). | Procoxae contiguous; pronotum more slender, 0.95–1.1 times as long as wide, only slightly constricted on anterior third; erect interstitial setae abundant, confused; a short median carina from epistomal margin to level of antennal insertion; host <i>Pinus</i> ; 3.1–5.3 mm | <i>Hylurgus</i> |
| — | Procoxae moderately separated; pronotum stouter, less than 0.85 times as long as wide, strongly constricted on anterior third; erect interstitial setae in uniseriate rows; a fine median carina from epistoma to middle of frons; hosts <i>Pinus</i> and other Pinaceae; 2.5–4.5 mm | <i>Tomicus</i> |

GENUS *XYLECHINOSOMUS* SCHEDL

Xylechinosomus Schedl, 1963:209. Type-species: *Xylechinus taunayi* Eggers = *Hylastes contractus* Chapuis, original designation (References in Wood & Bright c1992:4104–105)

Diagnosis: Metepisternal setae scalelike; antennal funicle 7-segmented, club apparently with four or more sutures; male frons impressed.

Description: Frons sexually dimorphic, male shallowly to strongly impressed, female convex to shallowly

concave; eye oval, entire; antennal scape elongate, funicle 7-segmented, club weakly flattened, apparently with four or more sutures; pronotum usually unarmed by crenulations, a few small crenulations or rugosities in two species; precoxal ridge entirely absent; basal crenulations on elytra low, rather well formed; vestiture hairlike, with ground vestiture of scales in some species.

Distribution: Eight species have been reported from southern Brazil, Chile, and Argentina.

Biology: All species breed in *Araucaria* species. Apparently all species are phloeophagous.

Key to the Species of *Xylechinosomus*

- 1. Interstitial setae consisting of short, scales or hair, and long, erect, hairlike setae, long setae present on all declivital interstriae 2
- Interstitial setae consisting of short, recumbent scales and long, erect, hairlike setae; erect setae absent from most or all of declivital interstriae 2 and 4 4
- 2(1). Body larger; interstitial ground setae on declivity abundant, short, each scale about twice as long as wide; male frons with a strong, transverse impression near middle, a feeble, median carina often present; Brazil; *Araucaria brasiliensis*, *A. Angustifolia*; 3.0–3.4 mm ***brasiliensis*** (Schedl)
- Body smaller than 2.4 mm; interstitial ground setae either hairlike or sparse (subscalelike), each at least six times as long as wide 3
- 3(2). Discal interstriae at least three times as wide as striae, stria punctures very small; all elytral setae hairlike, very long and abundant, confused, particularly on declivity; frontal impression not as strong, a weak, median carina on lower half; Brazil; *Araucaria brasiliensis*; 2.4 mm ***hirsutus*** Schedl
- Discal interstriae about twice as wide as striae, stria punctures distinctly larger; elytral setae with long, erect setae confused on disc, almost uniseriate on declivity, short, ground setae present on declivity; lower half of male frons with no indication of a median carina; Brazil; *Araucaria angustifolia*; 2.3–2.4 mm ***pilosus*** Wood
- 4(1). Body larger; pronotum and elytra closely clothed by an abundant ground cover of scales; declivital interstriae 1 and 3 moderately elevated, 2 impressed; frons conspicuously concave and armed by a strongly elevated median carina; Argentina, Chile; *Araucaria araucana*; 2.5–3.0 mm ***valdivianus*** (Eggers)
- Body usually smaller than 2.5 mm; pronotum without scales, its vestiture hairlike; declivital interstriae about equally convex; frons without a median carina 5
- 5(4). Elytral declivity somewhat flattened on lower half, ventrolateral margin subacutely elevated from sutural apex to apex of interstriae 7; Brazil; *Araucaria angustifolia*; 2.1–2.8 mm ***contractus*** (Chapuis)
- Elytral declivity more narrowly convex, ventrolateral margin normally rounded, not conspicuously elevated; smaller species 6
- 6(5). Discal interstriae as wide as striae, crenulations absent; declivital interstriae 2 weakly convex, not impressed; ground setae on elytra minute, as wide or wider than long; male lower frons flat, area above frontal impression rugose-reticulate; Brazil (Rio Grande do Sul); 1.3 mm ***lucianae*** Mecke
- Discal interstriae almost twice as wide as striae, crenulations weakly to moderately elevated; declivital interstriae 2 weakly impressed, flat; ground setae on elytra of small scales, most longer than

- wide; male lower frons shallowly concave, surface smooth and brightly shining from epistoma to vertex 7
- 7(6). Discal interstriae about twice as wide as striae, punctures with anterior margin forming a fine tubercle, each tubercle about half as wide as an interstriae; erect interstitial setae rather stout, each about equal in length to half distance between rows; Brazil; *Araucaria angustifolia*; 1.3–1.5 mm *minimus* Schedl
- Discal interstriae about as wide as striae, crenulations rather coarse at base, as wide as an interstriae, becoming more nearly tuberculate at base of declivity; erect, interstitial setae more slender, each distinctly longer than distance between rows; Brazil; *Araucaria angustifolia*; 1.9–2.0 mm *sachtlebeni* Schedl

Xylechinosomus brasiliensis (Schedl)

Xylechinosomus brasiliensis (Schedl, 1951:95 (*Pseudohylesinus*). Syn-types, sex?; Nova Teutonia, Santa Catarina, Brazil; 2 ♀ in NHMW, Wien, others in Plaumann Collection (Synonymy and references in Wood & Bright c1992:105)

Xylechinosomus araucariae Schedl, 1963:210. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien

Diagnosis: Erect, declivital, hairlike setae present on interstriae 2 and 4; declivital ground vestiture of short, abundant scales; a larger species.

Female: Length 3.0–3.4 mm, 2.1 times as long as wide; color brown, vestiture pale. Frons convex, a weak interocular impression near middle, a weak, median carina from epistoma to upper level of eyes; surface very closely, coarsely, deeply punctured, becoming subgranulate on upper fourth; vestiture of fine, short hair. Pronotum 0.74 times as long as wide; widest at base, sides weakly arcuate on basal half, a strong constriction on anterior fourth; surface densely, rather coarsely, deeply punctured, subgranular on anterior fourth and basal third; vestiture of fine, short, recumbent hair of moderate abundance. Elytra 1.3 times as long as wide, 2.1 times as long as pronotum; striae weakly impressed, punctures small, deep; interstriae about three times as wide as striae, weakly convex, with numerous, confused, sharp crenulations, largest one-fourth as wide as an interstriae, numerous, confused, very small punctures also present; declivity broadly convex, steep, crenulations reduced in size and number to rows of uniseriate tubercles; vestiture of short ground vestiture (hairlike on disc, short scales on declivity, each scale about as long as wide) and long, erect, confused hair on disc, uniseriate bristles on declivity at least on interstriae 1–4.

Male: Similar to female except interocular frontal impression deeper, longer (occupying lower half of upper half of area below upper level of eyes); elytral interstriae more nearly granular, few very small crenulations present.

Distribution: Brazil: Curitiba, Parana, 13-I-1969, C.W. & L. O'Brien; Santa Catarina, Nova Teutonia; Rio Negro, Parana, 9-VI-1973, *Araucaria angustifolia*, Schoenherr.

Hosts: *Araucaria angustifolia*, *A. brasiliana*.

Notes: Seven specimens were examined. Two of these males were compared to the male holotype of *Pseudo-*

hylesinus araucariae Schedl. I compared 2 syntypes of *X. brasiliensis* Schedl directly to the type series of *araucariae* by. I regard them as 1 species.

Xylechinosomus hirsutus Schedl

Xylechinosomus hirsutus Schedl, 1963:211. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:105)

Diagnosis: Subcrenulate pronotal granules and very long, abundant, confused, hairlike, interstitial setae distinguish this species.

Male: Similar to female except lower third of frons flattened, carina absent; pronotal punctures normal, lateral margins not elevated; elytral vestiture less abundant, some setae shorter (one-fourth as long) and resembling a ground cover.

Female: Length 2.3–2.4 mm, 2.0 times as long as wide; color dark reddish brown, vestiture pale. Frons convex on upper third, transverse interocular impression rather long (on lower half of upper half), almost flat to weakly convex on lower third; a weak median carina on upper half of lower half; shining, with fine, sparse punctures on upper half, slightly larger and closer below; vestiture of fine, rather short, inconspicuous hair. Pronotum 0.75 times as long as wide; sides convergently arcuate on basal three-fourths, moderately constricted on anterior fourth; surface shining, very closely, rather deeply punctured, lateral margin of each puncture elevated, becoming subtuberculate in lateral areas; vestiture of fine, rather long, moderately abundant hair. Elytra 1.3 times as long as wide, 2.0 times as long as pronotum; striae not impressed, punctures small, deep; interstriae indistinctly convex, about three times as wide as striae, shining, with closely set, confused, rather high rugae, each about one-third as wide as an interstriae; declivity broadly convex, steep; interstriae with uniseriate tubercles; vestiture of abundant, confused, hairlike setae from base to apex, longest setae equal in length to width of two interstriae on disc and sides, equal to width of one interstriae on declivity.

Distribution: Brazil: Curitiba, Parana, 13-I-1969, C.W. & L. O'Brien; Telemaco Borba, Parana, *Pinus taeda*, Pedrosa-Macedo.

Hosts: *Araucaria angustifolia*, *A. brasiliana*.

Notes: I compared 1 male and 1 female to the Nova Teutonia type series of *X. hirsutus* Schedl.

Xylechinomus pilosus Wood

Xylechinomus pilosus Wood, 1985:274. Holotype ♂; Curitiba, Parana, Brazil; USNM, Washington (References in Wood & Bright c1992:105)

Diagnosis: Distinguished from *hirsutus* Schedl by the less abundant, shorter pronotal and elytra hair; by the absence of granules on the lateral margins of female pronotal punctures; and by other characters mentioned in the above key and below.

Male: Similar to female except frons rather strongly impressed from upper level of eyes to one-fourth frons length above epistoma, transversely flat, deepest near middle; hairlike setae on elytral disc slightly longer and interstitial crenulations on disc larger (each up to half width of an interstriae).

Female: Length 2.3–2.4 mm, 2.1 times as long as wide; color brown. Frons weakly convex from epistoma to upper level of eyes, without an interocular impression or carina; surface shining, punctures moderately large, shallow, obscure in central area, deeper on lower third; vestiture of short, sparse hair. Pronotum 0.76 times as long as wide; widest at base, sides subparallel on basal half, a moderate constriction on basal half; surface as in male *hirsutus*. Elytra 1.4 times as long as wide, 2.1 times as long as pronotum; striae weakly impressed, punctures rather coarse, deep; interstriae about twice as wide as striae, shining, crenulations very small, less than one-fourth as wide as striae, subacute, a setiferous puncture on posterior slope of each; declivity convex, steep, interstriae each armed by a row of small tubercles; vestiture on disc of moderately abundant hair, each seta about equal in length to width of an interstriae, on declivity a sparse ground cover of pointed scales (each about six times as long as wide) and uniseriate rows of long hairlike, bristles (length of each equal to distance between rows).

Male: Similar to female except frons rather strongly impressed from upper level of eyes to one-fourth frons length above epistoma, deepest (transversely flat) near middle; hairlike setae on elytral disc slightly longer and interstitial crenulations on disc larger (each up to half width of an interstriae).

Distribution: Brazil: Curitiba, Parana, 13-I-1969, C.W. & L. O'Brien.

Hosts: *Araucaria angustifolia*.

Notes: The above treatment was based on the male holotype and female allotype of *X. pilosus* Wood.

Xylechinomus valdivianus (Eggers)

Plate IV

Xylechinomus valdivianus (Eggers), 1942:15 (*Xylechinus*). Holotype, sex?; Valdivia, Chile; Hamburg Museum, lost (References in Wood & Bright c1992:15)

Diagnosis: This species is distinguished by having both pronotum and elytra densely clothed by variegated scales; by having declivital interstriae 1 and 3 modestly elevated; and by the strong, median, frontal carina in both sexes.

Male: Similar to female except frons moderately, broadly concave from upper level of eyes to level of antennal insertion, concavity deep in some specimens; scales on frons less numerous, carina higher; some specimens with a long, median, subcarinate crest on pronotum.

Female: Length 2.5–3.0 mm, 2.2 times as long as wide; color dark brown, clothed by a variegated pattern of dark and pale scales. Frons basically, weakly convex except central third with a circular, concave impression, a median carina from epistoma to deepest point in concavity, carina very strong on its lower half, weak above; surface finely, closely punctured; vestiture mostly scale-like in concavity to above eyes, hairlike elsewhere, short. Pronotum 0.82 times as long as wide; outline as in *pilosus* Wood except constriction on anterior fourth distinctly deeper; surface very closely, rather deeply punctured, lateral areas sparsely asperate, a few small granules continued to disc; vestiture of abundant scales, each slightly longer than wide, color variegated dark and pale. Elytra 1.5 times as long as wide, 2.1 times as long as pronotum; striae weakly impressed, punctures moderately large, deep, close; interstriae about twice as wide as striae, weakly convex on disc, 1 and 5 slightly, 3 more strongly convex toward declivity, each bearing a small, pointed, bristle-bearing tubercle; declivity moderately steep, basically convex, with interstriae 1, 3, 5, 9 moderately elevated, 3 and 9 join apically; vestiture of abundant dark and pale scales in a variegated pattern, each scale about as wide as long; tubercles on interstriae bearing erect, stout bristles on all discal interstriae and all except 2 and 4 on declivity.

Distribution: Chile: Caramavida, 5-II-1953, 20-XII-1956, 1000 m, *Araucaria* ramas, L.C. Pena; Cautin, Conguillio, 13-II-1979, J. Solervicens; Parque N. Nahuelbuta, 38 km W Angol, 4300 ft., 13-II-1968, C.W. & L. O'Brien; Pemehue, I-1896; Malleco, P.H. Nahuelbuta, Pehuenco, 22-I-1985, corteza de *Araucaria araucana*, S. Rottman; Malleco, Nahuelbuta, 4-II-1980, J. Solervicens. Argentina (specimens not seen).

Hosts: *Araucaria araucana*.

Notes: The above treatment was based on 34 specimens, 6 of which were compared to the type series of *Xylechinus valdivianus* Eggers.

Xylechinomus contractus (Chapuis)

Plate IV

Xylechinomus contractus (Chapuis), 1869:23 (*Hylastes*). Syntypes, sex?; St. Paul, Brazil; IRSNB, Brussels (Synonymy and references in Wood & Bright c1992:105)

Xylechinus taunayi Eggers, 1928:84. Lectotype, sex?; Campos do Jordao, Sao Paulo, Brazil; USNM, Washington, designated by Anderson & Anderson 1971:33

Diagnosis: Distinguished by the absence of erect setae on flattened declivital interstriae 2 and 4; and by the subacutely elevated ventrolateral margin of the declivity.

Male: Similar to female except upper half of frons rather strongly, subconvexly impressed; erect bristles on declivity shorter.

Female: Length 2.1–2.8 mm, 2.2 times as long as wide; color brown, vestiture pale. Frons convex from epistoma to above eyes; surface shining, punctures close, moderately large, deep; vestiture of short, sparse, fine, hairlike setae. Pronotum 0.77 times as long as wide; sides subparallel on basal half, a moderate constriction on anterior third; surface smooth, shining, punctures close, deep, moderately large; vestiture of short, sparse, hairlike setae, a few longer, coarse setae in lateral areas. Elytra 1.4 times as long as wide, 2.3 times as long as pronotum; striae weakly impressed, punctures rather coarse, deep, close; interstriae slightly less than twice as wide as striae, shining, crenulations acute, almost uniseriate, each about three-fourths as wide as an interstriae, posterior slope abrupt, more or less concavely impressed by large, bristle-bearing puncture; declivity convex above, rather steep, moderately impressed on lower half, interstriae 1, 3, 5 each bearing a row of fine tubercles, 2 and 4 unarmed, ventrolateral margin moderately elevated from suture to apex of 7; vestiture on disc and sides of ground cover of fine, short, recumbent hair; ground cover on declivity of abundant, short scales, each scale as long as wide, and interstitial rows of erect bristles (except absent on 2 and 4 on declivity), each bristle as long as distance between rows, spaced within a row by length of a bristle.

Distribution: Brazil: Curitiba, Parana, 13-I-1969, C.W. & L. O'Brien; Caieras, Sao Paulo, 30-VII-1955, H.F.G. Sauer.

Hosts: *Araucaria angustifolia*.

Notes: The above was based on the 2 female syntypes in the Chapuis Collection that were compared to my 21 specimens from Brazil.

Xylechinosomus lucianae Mecke

Xylechinosomus lucianae Mecke, 2004:217. Holotype, sex?; San Francisco de Paula Pro-Mata, Rio Grande do Sol, Brazil; Zool. Inst. Universitat Tubingen, Germany

Diagnosis: Distinguished from *minimus* Schedl by having the discal interstriae as wide as the striae and without crenulations; by the weakly convex declivital interstriae 2; by the minute ground setae on the elytra, each scale as wide or wider than long; and by the male frons being almost flat on the lower half, the area above the eyes rugose-reticulate.

Male: Length 1.3 mm, 2.2 times as long as wide; elytra dark brown, pronotum very dark brown. Frons feebly concave (almost flat on lower half, moderately concave on upper area to vertex), reticulate below, becoming rugose-reticulate toward vertex; punctures very small, shallow, moderately close; sparse, minute, hairlike setae from upper level of eyes to epistoma, longer and more numerous on epistoma. Pronotum 0.85 times as long as wide; sides on basal two-thirds moderately arcuate, a slight constriction before rather broadly rounded ante-

rior margin; surface strongly reticulate, weakly rugose on posterior half of disc, punctures small, shallow, close, uniformly distributed; vestiture of fine, short, recumbent hair uniformly distributed, about four stout erect setae on anterolateral area. Elytra 1.5 times as long as wide, 2.4 times as long as pronotum; disc occupying 66 percent of elytra length; striae feebly impressed, punctures rather large, deep; interstriae as wide or slightly wider than striae, almost smooth, shining, punctures minute, close, confused. Declivity steep, broadly convex; striae 1–3 about as on disc, punctures slightly smaller; interstriae 1–3 equally, weakly convex, without tubercles. Vestiture of minute ground scales on declivity, each scale as wide or wider than long; longer, erect, stout setae on interstriae 5–9 on posterior half of elytra.

Female: Similar to male except frons moderately, evenly convex; striae punctures on disc mostly longer; striae 1 and 2 on lower declivity more distinctly impressed, these punctures distinctly smaller.

Distribution: Brazil (Rio Grande do Sul): San Francisco de Paula Pro-Mata, 22-XI-1999, *Araucaria angustifolia*, R. Menke.

Notes: The above treatment was based on 2 male and 2 female paratypes.

Xylechinosomus minimus Schedl

Xylechinosomus minimus Schedl, 1963:212. Holotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:105)

Diagnosis: This species is distinguished from others in the genus by the very small size; and by the short, erect interstitial setae.

Male: Similar to female except frons broadly, shallowly concave from level of antennal insertion to upper level of eyes, surface smooth, shining, punctures rather small; pronotal punctures slightly smaller.

Female: Length 1.3–1.6 mm, 2.2 times as long as wide; color dark brown, vestiture pale. Frons moderately concave from level of antennal insertion to vertex; punctures coarse, deep, surface between punctures smooth, shining below, obscurely reticulate above; a distinct transverse impression from epistomal margin to level of antennal insertion; hairlike vestiture fine, short, inconspicuous. Pronotum 0.82 times as long as wide; sides on basal half subparallel, feebly arcuate, anterior third moderately constricted; surface smooth, shining, punctures coarse, rather close (spaced by diameter of a puncture), rather deep; vestiture of short, fine, recumbent hair. Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; striae rather weakly impressed, punctures coarse, deep, close; interstriae only slightly wider than striae, shining, subtuberculate crenulations uniseriate, each crenulation about three-fourths as wide as an interstriae, posterior face of crenulation abrupt, marked by a setiferous puncture; declivity broadly convex, rather steep, striae narrower than on disc, interstriae 2 and 4 devoid of tubercles, those on 1, 3, 5–9 minute; vestiture of ground cover of

moderately coarse, short, recumbent setae on disc and sides, on declivity of abundant short scales, and rows of erect interstitial bristles (except absent on declivital interstriae 2 and 4), each bristle about half to two-thirds as long as distance between rows, spaced within a row by length of a bristle.

Distribution: Brazil: Curitiba, Parana, 13-I-1969, C.W. & L. O'Brien; Nova Teutonia, Santa Catarina; Santa Catarina, 1930, W. Ehrhardt; Rio Negro, Parana, 9-VI-1973, *Araucaria angustifolia*, J. Schoenherr; Telemaco Borba, Parana, 31-X-2003, Klabin Papel e Cellulose, a-pinene + ethanol + sulcitol trap, *Pinus taeda* stand, C.A.H. Flechtmann.

Notes: The above treatment was based on my female homotype of *X. minimus* Schedl and on 9 other specimens to which it was compared.

Xylechinosomus sachtlebeni Schedl

Xylechinosomus sachtlebeni Schedl, 1963:209. Holotype ♀; Nova Teutonia, Santa Catarina; NHMW, Wien (References in Wood & Bright c1992:105)

Diagnosis: Distinguished from allied species by the absence of erect bristles on declivital interstriae 2 and 4; by the large punctures on the discal striae; by the rounded (normal) ventrolateral margin of the declivity; and by the much longer interstitial bristles that are uniseriate from base to apex.

Male: Similar to female except frons with a very slight, small impression at middle; interstitial setae slightly shorter; on declivity slightly stouter.

Female: Length 1.9–2.0 mm, 2.1 times as long as wide; color dark brown, elytra somewhat reddish brown. Frons moderately convex from weak epistomal impression to upper level of eyes; surface smooth, shining, punctures rather small, mostly spaced by one to two diameters of a puncture; vestiture short, sparse, hairlike. Pronotum 0.75 times as long as wide; widest at base, sides weakly arcuate, subparallel on basal half, anterior third with a moderate constriction; surface smooth, shining, punctures small, deep, spaced by one to two diameters of a puncture; vestiture of fine, moderately long, recumbent hair. Elytra 1.5 times as long as wide, 2.2 times as long as pronotum; striae distinctly impressed, punctures large, deep, close; interstriae slightly narrower than striae, shining, tuberculate crenulations uniseriate, almost as wide as interstriae, posterior face of each tubercle steep, marked by a setiferous puncture; declivity broadly convex, rather steep; striae narrower; interstriae 2 and 4 unarmed, tubercles on 1, 3, 5–9 much smaller than on disc, 2 feebly impressed; ground vestiture on disc very sparse, of fine, short hair, on declivity of abundant scales, each scale as long as wide; erect interstitial setae in uniseriate rows, each seta 1.5 times as long as wide on disc, slightly longer on declivity, spaced within a row by half length of a bristle, absent on declivital interstriae 2 and 4.

Distribution: Brazil: Curitiba, Parana, 13-I-1969, C.W. & L. O'Brien; Nova Teutonia, Sao Paulo.

Hosts: *Araucaria angustifolia*.

Notes: One male and 1 female were examined; these were compared to Schedl's type series.

Species Not Seen

Xylechinosomus humilus (Blanchard)

Xylechinosomus humilus (Blanchard), 1851:427 (*Hylesinus*). Holotype, sex?; Iles Valdives, Chile; not located (References in Wood & Bright c1992:105)

Efforts to locate this species have not been successful. The original description given by Chapuis 1869:24 is as follows:

"*H. humilus* Blanchard: Oblongus, opacus, niger; antennis et tarsi flavis; capite coriaceo-punctato, rostro brevi, fortiter et acute carinato; prothorace longitudine latiori, fortiter constricto, versus basin subtiliter reticulato-punctato, ad apicem punctato, linea media obsoleta; elytris subtiliter striato-punctatis, interstitiis rugoso-punctatis, parce pubescentibus, setis brevibus, latis, squammaeformibus uniseriatum ornatis, declivitate granulatis." Length 2.5 mm, Chili, Iles Valdives.

Blanchard (in Gay 1851/1852, p. 428) states that this species "fue hallada en los arboustos de la provincia de Coquimbo." The "Chili Iles Valdives" cited by Chapuis (1869:24) was either an error or else "Isles Valdives" must be a minor locality in Coquimbo Province which is not cited in atlases available to me. Chapuis gave no indication as to why he replaced "Coquimbo Province" of Blanchard with "Iles Valdives." Because the type apparently came from the beating of shrubs in Coquimbo Province, not from a definite host, it is possible the species belongs to another genus. I have not seen Gay's illustration of the type.

Xylechinosomus paranaensis (Schoenherr)

Xylechinosomus paranaensis (Schoenherr), 1994:63 (*Pteleobius*). Holotype, sex?; Telemaco-Borba, Parana, Brazil; DZUFF, Curitiba

Requests for a loan of type material were not answered.

GENUS *SINOPHLOEUS* BRETHES

Sinophloeus Brethes, 1922:433. Type-species: *Sinophloeus porteri* Brethes, monobasic (References in Wood & Bright c1992:105)

Diagnosis: Frons with a strongly developed, median carina, surface of frons strongly impressed in male, moderately impressed in female; antennal funicle 7-segmented; pronotum unarmed by asperities, not constricted on anterior third.

Description: Frons sexually dimorphic, strongly concave to vertex in male, moderately to below upper level of eyes in female, a strong median carina in both sexes; antennal funicle 7-segmented, club slightly flattened, marked by four sutures; pronotum wider than long, devoid of asperities; elytra with striae punctures present.

Distribution: Western parts of southern South America.

Biology: Breeds in branches of *Araucaria* spp. It is said to be phloeophagous (Schedl 1966:43).

Notes: The type-species, *porteri* Brethes, was found (see pp. 53, 57). A second, much smaller species (about 2.1 mm) was incorrectly named by Schedl as *Xylechinus spathifer* Schedl (see below on page 57). Unfortunately, the page of my notes containing the name and details of the transfer were lost during travel before a record could be made. (This species was from southern Chile or adjacent Argentina and is from *Nothofagus*). It is in the NHMW, Wien collection under a different generic name, and in the USNM, Washington.

Sinophloeus destructor Eggers

Plate IV

Sinophloeus destructor Eggers, 1942:15. Holotype, sex?; Chile; Hamburg Museum, lost

Diagnosis: Easily recognized by the distinctive frons; by the presence of subtuberculate nodules between punctures in a stria row; by the very coarse, long setae on the anterolateral areas of the pronotum; and by the host.

Male: Similar to female except frontal concavity extending from vertex to lower fourth of frons, much wider; deeper; carina higher and longer; anterolateral areas of pronotum with several low rugae, long bristles more numerous.

Female: Length 2.4–3.1 mm, 2.2 times as long as wide; color almost black, elytra usually reddish brown, vestiture often pale, especially on elytra. Frons with median half moderately concave from distinctly below upper level of eyes to middle of frons; an acutely elevated median carina from deepest point of concavity to two-thirds distance toward epistomal margin; surface obscurely subreticulate, punctures moderately large, close, deep, finer below; vestiture of fine, sparse, short, inconspicuous hair, a modest epistomal brush arising immediately above epistomal margin. Pronotum 0.73 times as long as wide; widest on weakly arcuate, subparallel basal half, moderately constricted on anterior fourth; surface smooth, shining, without any tubercles or granules, punctures moderately coarse, very close, deep; vestiture of fine, short hair at base of disc, becoming longer anteriorly, anterior margin and anterior half of lateral margin bearing several (about 40) very long, coarse, dark bristles. Elytra 1.6 times as long as wide, 2.3 times as long as pronotum; basal margin of each elytron armed by about 10 coarse, marginal crenulations, bases of interstriae 2–5 armed by several (total of 15) submarginal crenulations; striae not impressed, punctures small, deep, obscure, spaces between punctures within a row armed by conspicuous subtuberculate nodules to base of declivity; interstriae about twice as wide as striae, shining, closely subcrenulate, some crenulations subacute, their posterior slope steep and marked by a setiferous pore; declivity very broadly convex (somewhat flattened), moderately steep, stria punctures much larger than on disc,

interstriae narrower, each armed by a row of moderately large, pointed tubercles, interstriae 1 feebly elevated; vestiture of ground cover of short setae, slender, almost hairlike on disc, stout, almost scalelike on declivity, a few irregularly placed, very long interstitial bristles on disc and sides (on interstriae 3 and 5 only?).

Distribution: Argentina to Chile.

Argentina: Cited by Bright & Skidmore (1994:24).

Chile: Alto Caicupil, 12-I-1953, L.E. Pena; Arauco Caramavida, 20-XII-1956, 1200 m, *Araucaria* (ramas), G. Kushel; Cautin, Conquillio, 13-V-1979, J. Solervicens; Cautin, P.N. Los Paraguas, 20-II-1962, N. Elgueta; Cautin, P.N., Las Paraguas, 20-III-1962, N. Elgueta; Chillan, Elng Nr. 115, 1927, W. Zirk (cotype); Malleco, 30-I-1962, 1200 m, T. Valencia; Prov. Malleco, Lonquimay, 22-XII-1956, *Araucaria* (ramas), G. Kushel; Malleco, Nahuelbuta, 7-II-1980, *Araucaria araucana*, J. Solervicens; Malleco Galleque, 8-II-1991, *Araucaria araucana*, J. Solervicens; Malleco La Fusa, Lonquimay, 31-XII-1967, 900–1200 m, L.E. Pena; Malleco Liucura, Lonquimay, 1-9-I-1969, L.E. Pena; Pichinahuel, 8-II-1953, L.E. Pena; Prov. Malleco, Pemehue, 1350 m, 26-I-1946, *Araucaria*, G. Kushel; Malleco, 30-I-1962, 1200 m, T. Valencia; Pemehue, II-1894, 1896, Germain; Prov. Cautin, II-1921, Roble (= *Nothofagus obliqua*), C.E. Porter; Pemehue, 1894, II-1896, Germain; Nahuelbuta (Sudchile), 12-XI-1961, *Araucaria araucana*, in phloem von beblatterten Asten, W. Ruhm (Schedl 1966:43); P.N. Villarica, 2-II-1977, Solervicens.

Hosts: *Araucaria araucana*.

Biology: Schedl (1966:43) states “in phloem von beblatterten Asten.”

Notes: The report by Porter from Roble (= *Nothofagus obliqua*) in Brethes (1922:433) and Schedl (1966:43) must represent either an error in recording the host, or else Porter’s species was not the same as the one reported here. All other records are from *Araucaria araucana*. The above treatment was based on 41 specimens (see p. 57).

GENUS *XYLECHINUS* CHAPUIS

Xylechinus Chapuis, 1869:36. Type-species: *Dendroctonus pilosus* Ratzeburg, monobasic (Synonymy and references in Wood & Bright c1992:114–115)

Pruiniphagus Murayama, 1958:930. Type-species: *Pruiniphagus gumensis* Murayama, original designation

Squamasinus Numberg, 1964:431. Type-species: *Squamasinus chilensis* Numberg, original designation

Xylechinops Browne, 1973:283. Type-species: *Xylechinus australis* Schedl, original designation

Diagnosis: This genus is distinguished from other Tomicini genera by the 5-segmented antennal funicle and scalelike setae on the metepisternum.

Description: Frons usually not sexually dimorphic; median frontal carina sometimes present; antennal funicle 5-segmented, club conical, slightly flattened; pronotum unarmed or armed by asperities; procoxae moderately

separated; elytral striae indicated, sculpture rather simple.

Distribution: There are 36 species listed worldwide on all inhabited continents (Wood & Bright c1992:114–119), 12 of which were cited from South America and 9 from adjacent Central America.

Biology: All species are monogynous and phloeophagous. They breed in both coniferous and broadleaf hosts in biramous parental galleries in branches, seedlings, or small diameter tops of their hosts. In the dozen or more species known to me, attacks were made in unthrifty parts of standing trees near green tissue. I have never seen them in slash or felled trees.

Key to the Species of *Xylechinus*

- 1. Anterolateral areas of pronotum armed by seven or more acute, rather high asperate crenulations on each side (see also *huapiae*) 2
- Anterolateral areas of pronotum entirely unarmed by acutely pointed asperities (see also couplet 16) 6
- 2(1). Elytral ground cover of short, very stout scales, each scale about as wide as long, their apex rounded; erect interstitial bristles entirely absent; declivital striae 1 and 2 with punctures as large as on disc; punctures on pronotum very fine, shallow; female frons strongly convex, distinctly protuberant above epistoma; elytral declivity broadly sulcate between left and right interstriae 3; Chile; 2.2–2.4 mm (*variegatus* very much like this but lower frons more distinctly impressed) *chiliensis* (Nunberg)
- Elytral interstriae each with a row of erect bristles, each bristle about one and one-half to twice length of ground scales; punctures on declivital striae 1 and 2 conspicuously smaller than on disc 3
- 3(2). Scutellar notch at suture at base of elytra unusually deep, posterior margin of pronotum at median line armed by a large, acutely pointed spine projecting into scutellar notch; setae on pronotum stout, each about four to five times as long as wide, interstitial ground setae pale, each two to three times as long as wide, erect setae mostly dark in color, each about six times as long as wide; Argentina; 2.5 mm *nigrosetosus* Hagedorn
- Scutellar notch normal; posterior margin of pronotum unarmed by a large median spine 4
- 4(3). Basal area of each elytron with 12 or more coarse, submarginal crenulations on interstriae 2 to 5; discal interstriae each with a row of many tubercles, tubercles larger toward declivity; female frons with a very slight, short median carina at level of ocular sinuation; Chile; 2.3 mm *tuberculifer* Wood
- Basal area of elytra with few if any submarginal crenulations; interstriae without tubercles on disc or declivity, an occasional small granule present; frons with no indication of a median carina 5
- 5(4). Elytral ground cover of slender, often pointed scales, each scale about three to six times as long as wide; erect interstitial bristles in rows, almost scalelike, each about one and one-half to two times as long as ground scales, spaced within a row by almost twice length of a bristle; scales about 60 percent dark, 40 percent pale, variagated; punctures on pronotum moderately coarse, close, deep; female frons weakly convex, somewhat impressed above epistoma; elytral declivity convex; Chile; 1.8–2.0 mm *maculatus* Schedl
- Elytral interstriae with ground cover of short scales, each scale only slightly longer than wide, their apices rounded, each interstriae with a row of erect bristles, each bristle slightly longer than scales; pronotum with very small, shallow, close punctures; elytral declivity impressed as in *chiliensis* except punctures on striae 1 and 2 much smaller than on disc; Chile; 2.4 mm *squamatilis* Wood
- 6(1). Body stouter, 1.8–2.1 times as long as wide, elytra 1.6 to 1.7 times as long as pronotum; vestiture on pronotum slender, mostly hairlike; elytra sexually dimorphic, declivital interstriae 2 and 4 impressed and unarmed, 3 (and sometimes 1) armed by denticles in both sexes, larger and higher in male 7

TOMICINI

- Body more slender, 2.3 times as long as wide, elytra 2.3 times as long as pronotum; vestiture on pronotum clearly scalelike, varying from as long as wide to six times as long as wide; elytral interstriae without any tubercles on disc or declivity 8
- 7(6). Male frons concave; pronotum disc smooth, shining, more coarsely punctured; 11 crenulations on basal margin of each elytron coarser; discal interstriae without tubercles; male declivital interstriae 3 armed by a row of pointed, moderately coarse denticles, 1 unarmed; Argentina; 2.0 mm *squamiger* Schedl
- Male frons convex; pronotum reticulate near base, punctures much smaller; 15 smaller crenulations on basal margin of each elytron; discal interstriae each armed by tubercles; male declivital interstriae 3 and base of 1 elevated and armed by tubercles; Argentina; 2.1–2.6 mm *imperialis* (Schedl)
- 8(6). Vestiture on pronotum slender, almost hairlike; elytral declivity rather uniformly convex, interstriae 1 higher than 3 9
- Vestiture on pronotum stout, scalelike, each less than four times as long as wide; elytral declivity variously impressed, interstriae 3 distinctly higher than 1 (except striae 1 and interstriae 2 impressed in *freiburgi* but interstriae 1 higher than 3) 10
- 9(8). Interstriae with ground cover on basal half of disc of fine, short hair, of short scales on posterior half of disc and declivity; erect interstitial setae of fine, short hair on disc and declivity; declivital striae 1 to 4 narrowly, rather deeply impressed; pronotum surface granular; punctures small, close, obscure; Brazil; 1.7 mm *minor* Eggers
- Interstitial ground setae of stout, pointed subscales; erect interstitial setae scalelike, each about four to six times as long as wide; pronotum surface almost smooth, punctures close, shallow, rather large; funicle 7-segmented; Chile; 2.3 mm *Sinophloeus porteri* Brethes
- 10(8). Elytral declivity convex, interstriae 2 not impressed (feebly in *freiburgi*), interstriae 1 at least as high as 3; frons flattened to concave, never armed by a median tubercle or carina 11
- Elytral declivity shallowly to moderately sulcate, interstriae 2 impressed, 3 higher than 1; frons with a median tubercle or carina in both sexes 12
- 11(10). Male frons planoconcave from epistoma to upper level of eyes; Brazil; 2.1 mm *freiburgi* Schedl
- Male frons rather strongly concave on median half from level of antennal insertion to upper level of eyes; Argentina; 1.7–2.1 mm *nahueliae* (Schedl)
- 12(10). Scales in ground cover on pronotum and elytra rather slender, each seta about four times as long as wide; median tubercle on frons at or slightly below middle; impression on elytral declivity very shallow; punctures on declivital striae 1 and 2 rather coarse; Chile; 2.4 mm *aconcaguensis* Wood
- Scales in ground cover on pronotum and elytra very stout, almost as wide as long; tubercle or carina on frons above middle; punctures on declivital striae 1 and 2 smaller 13
- 13(12). Ground scales on pronotum and elytra large, more abundant, concealing about 80 percent of surface; frons more broadly, more strongly flattened, median carina on upper half weak, somewhat obscure; declivital interstriae 3 more strongly elevated, scales covering summit profusely abundant; Chile; 2.6 mm *vittatus* Schedl
- Ground scales on pronotum and elytra smaller, less abundant, concealing no more than 50 percent of surface; frons more narrowly, less broadly impressed, median carina and/or tubercle stronger; declivital interstriae 3 less strongly elevated, scales on its summit not more abundant than elsewhere 14

- 14(13). Body more slender, 2.3 times as long as wide; elytral declivity not as steep, less strongly impressed below; female frons almost flat below upper level of eyes, a very weak median carina from just below upper level of eyes to well above eyes; Chile; 2.2 mm *declivis* Wood
- Body less slender, 2.2 times as long as wide; elytral declivity slightly steeper, more strongly impressed below; male (?) with denticle on upper frons strongly developed 15
- 15(14). Strial punctures on disc rather coarse, interstriae very slightly wider than striae; base of interstriae 2 and 3 (combined) armed by about five submarginal crenulations; Chile; 1.9 mm *variegatus* (Chapuis)
- Strial punctures on disc smaller, interstriae twice as wide as striae; bases of interstriae 2 and 3 (together) with one or two submarginal crenulations; female with obscure asperities on pronotum 16
- 16(15). Declivity less strongly, more narrowly impressed, especially on lower half; ground setae on discal interstriae as wide as long (subcircular), erect setae more slender, at least eight times as long as wide; frontal setae finer, slightly shorter, more numerous; Chile; 2.6 mm *solervicensi* Wood
- Declivity more strongly, more broadly impressed, especially on lower half; interstitial ground setae on disc slightly longer than wide (elongate), erect setae stouter, about four to six times as long as wide; frontal setae coarser, longer, less numerous; Chile; 2.0 mm *huapiae* (Schedl)

Xylechinus chiliensis (Nunberg)

Xylechinus chiliensis (Nunberg), 1964:432 (*Squamosinus*). Holotype, sex?; Chili; NHMB, Budapest (Synonymy and references in Wood & Bright c1992:114–115)

Xylechinus sulcatus Schedl, 1966:100. Holotype ♀; El Hoyo, Chubut, Argentina; NHMB, Budapest (References in Wood & Bright c1992:119). *New synonymy*

Diagnosis: Anterolateral area of pronotum armed by several acutely pointed crenulations; punctures on pronotum fine, shallow; elytral scales about as wide as long; elytral declivity impressed between interstriae 3, broadly, shallowly sulcate.

Female: Length 2.2 mm, about 2.1 times as long as wide; color very dark brown, scalelike vestiture in variegated pattern (60 percent dark, 40 percent pale). Frons moderately convex, a slight impression at level of antennal insertion; surface obscurely reticulate, punctures rather fine, close, obscured by numerous scales. Pronotum 0.82 times as long as wide; widest at base, sides arcuately converging to weak constriction on anterior fourth; anterolateral areas armed on each side by about 5–7 acutely elevated crenulations, surface minutely reticulate-granulate, punctures fine, shallow, close, obscure; vestiture of rather abundant scales, each scale slightly longer than wide; elytra 1.6 times as long as wide, 1.9 times as long as pronotum; about three submarginal crenulations at base of interstriae 2–3; striae not impressed, punctures small, deep, very close; interstriae about twice as wide as striae, smooth, shining, punctures small, close, confused; vestiture of abundant scales, each scale as wide as long, without rows of erect bristles. Declivity steep, broadly impressed between broadly rounded interstriae 3; surface sculpture similar to disc.

Distribution: Argentina to Chile.

Argentina: Chubut, El Hoyo.

Chile: B. de Canquenes, Rancagua, E.P. Reed.

Notes: One female specimen was examined that was compared to Schedl's paratype of *sulcatus*. Schedl compared the holotype of *chiliensis* (Nunberg) and *sulcatus* Schedl and labeled them as the same species, although he never reported the synonymy. I confirmed this observation at NHMW, Wien in 1982.

Xylechinus nigrosetosus Hagedorn

Xylechinus nigrosetosus Hagedorn, 1909:737. Holotype ♂?; Argentina, Gebirge Neuquem; Hamburg Museum, lost (1 damaged syntype removed by Eggers in 1944, purchased by USNM, Washington, in 1945, taken on loan in 1945 by Schedl, now on loan to NHMW, Wien (References in Wood & Bright c1992:116)

Diagnosis: Distinguished by the absence of pronotal asperities; and by the presence of a large, pointed median spine on posterior margin of pronotum (no other scolytid with a similar spine).

Male (?): Length 2.4 mm, 2.2 times as long as wide; color medium brown (mature color?). Head missing from type. Pronotum 0.84 times as long as wide; surface largely obscured by oils and resin; posterior margin at median line extended slightly caudad (into scutellar notch) and armed by a large, conspicuous, sharply pointed spine, dorsal crest of spine longitudinally carinate; asperities absent; vestiture short, moderately abundant, rather stout (somewhat hairlike) on anterior one-third, very stout on posterior areas, about three times as long as wide. Elytra about 1.5 times as long as wide, about 1.9 times as long as pronotum; scutellar notch deeper than normal (to accommodate pronotal spine); apparently without submarginal crenulations;

striae narrow, slightly impressed, punctures small, rather deep; interstriae about three times as wide as striae, surface shining, punctures subgranulate, small, confused, central row of granules not larger. Declivity convex, rather steep; striae 1 to 4 deeply, narrowly impressed, shining, punctures obsolete; interstriae narrower than on disc, without tubercles. Vestiture of ground cover of slender scales, each about four to six times as long as wide, and central rows of erect scales, each about 1.5 times as long as ground setae, and varying from three to six times as long as wide, each less than half as long as distance between rows, spaced within a row by length of a seta; erect setae mostly darker in color, ground setae mostly pale (very poor condition); setae on declivity may consist mostly of erect scales.

Distribution: Argentina: Neuquen mountains.

Notes: The above treatment was based on the holotype, probably a male. This species was based on a syntypic series in the Hamburg Museum. During World War II, Eggers removed this and other selected specimens of other species and placed them in his personal collection because he feared the Hamburg Museum might be destroyed. This syntype became the holotype by survival, all others were destroyed when the Hamburg Museum was lost. It is in very poor condition.

Xylechinus tuberculifer Wood, n. sp.

Xylechinus tuberculifer Wood: Holotype ♀; Valparaiso, La Campana, Chile; MNHN, Santiago, designated below

Diagnosis: Anterolateral areas of pronotum with asperities; basal areas of each elytron with 12 or more coarse, submarginal crenulations at bases of interstriae 2–5; each discal interstriae with a row of tubercles that become larger toward the declivity.

Female: Length 2.3 mm, 2.0 times as long as wide; color very dark brown, scales variegated (about 50 percent dark, 50 percent pale). Frons moderately convex; epistoma with a small median tubercle at margin; weakly impressed at level of antennal insertion; surface rather coarsely reticulate, several small, subgranulate punctures, a feeble, shining longitudinal carina on central fourth; vestiture rather coarse, short, rather sparse. Pronotum 0.83 times as long as wide; widest at base, sides weakly arcuate, moderately converging cephalad from base; crenulations in lateral areas rather small; surface finely granulate, punctures rather small, shallow; vestiture of rather sparse scales, each 3–4 times as long as wide. Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; bases of interstriae 2–5 armed by about 12 coarse, submarginal crenulations; striae narrow, weakly impressed, punctures deep, close; interstriae about three times as wide as striae, shining, closely, rather deeply punctured, punctures near center subtuberculate, becoming tuberculate by base of declivity; vestiture of rows of scales (each almost as wide as long) on both margins, central row bearing erect bristles (each about four times as long as wide, almost twice as long as ground scales),

not longer on declivity. Declivity steep, convex; striae more deeply impressed than on disc; interstriae narrower, as wide as striae on lower half, 2–4 more strongly convex, their tubercles larger, in rows.

Distribution: Chile.

Type material: The female holotype was taken at Valparaiso, La Campana, Chile, 27-X-1978, 700 m, ex bosque higrofilo, I. Solervicens. The holotype is in the Museo Nacional de Historia Natural, Santiago.

Xylechinus maculatus Schedl

Xylechinus maculatus Schedl, 1951:18. Syntypes ♀; Chile, Quillota; MNHN, Santiago, and NHMW, Wien (References in Wood & Bright c1992:116)

Diagnosis: Anterolateral area of pronotum armed by crenulations; elytral ground scales slender, each about six times as long as wide, erect bristles present; elytral declivity convex, not impressed.

Male: Similar to female except frons shallowly impressed from epistoma to upper level of eyes, course setae on margins more abundant, longer; pronotal asperities small, obscure.

Female: Length 1.8–2.0 mm, about 2.1 times as long as wide; color very dark brown, variegated scales (60 percent dark, 40 percent pale). Frons essentially convex, a moderate, transverse impression from just above epistoma to just below upper level of eyes, its deepest point transversely, weakly convex, feebly concave longitudinally; surface apparently reticulate, punctures fine, close, obscure, sparse vestiture apparently not scalelike. Pronotum 0.84 times as long as wide; lateral crenulations coarse, in two clusters, one at anterolateral margin, another in lateral area about one-third pronotum length from anterior margin; surface shining, punctures rather coarse, close, deep; vestiture of abundant, slender scales, each scale three to six times as long as wide. Elytra about 1.7 times as long as wide, about 2.5 times as long as pronotum; submarginal crenulations obsolete at base of interstriae 2–4; striae feebly impressed, punctures rather coarse, close, deep; interstriae less than twice as wide as striae, shining, punctures small, confused, ground cover of slender scales, each scale four to six times as long as wide, erect bristles stout, each one and one-half to two times as long as ground scales, about half as long as distance between rows, spaced within a row by about twice length of a bristle. Declivity evenly, rather steeply convex; striae punctures distinctly smaller than on disc; vestiture similar to disc.

Distribution: Chile: Cord. Chillan, 1899, Germain; Choapa, 272 km N Panam, 19-XI-1985, 23-I-1986, *Sena comingii* var. *coquimbensis*, M. Elgueta; Quillota; Cerro Robles, P. Santiago, 7-IV-1968, 6100 ft., C.W. & L. O'Brien; Pucocuai, 20-XI-1940, No. 449, G.H. Schwabe; Talco, La Varga (E. Carrizall), 3-XI-1991, M. Elgueta; Valparaiso, L. Penueles, 12-XI-1975, E. Vasquez.

Hosts: *Nothofagus pumilis*, *Sena comingii* var. *coquimbensis*.

Notes: The above treatment was based on 17 specimens from Chile. I compared 1 female directly to a female syntype in NHMW, Wien.

Xylechinus squamatilis Wood, n. sp.

Xylechinus squamatilis Wood: Holotype ♀; Banos de Cauquenes, Rancagua, Chile; USNM, Washington, designated below

Diagnosis: Distinguished from *maculatus* Schedl by the smaller, less numerous pronotal asperities; by the shorter, broader scales in ground cover of the pronotum and elytra; by the steeper, moderately sulcate elytral declivity; and by the larger size.

Female: Length 2.4 mm, 2.0 times as long as wide; color very dark brown, vestiture of scales in variegated pattern (50 percent dark, 50 percent pale). Frons about as in *chiliensis* (Nunberg). Pronotum about as in *chiliensis* except surface smoother, shining, punctures shallow, small to minute punctures intermixed, close. Elytra as in *chiliensis* except 1.4 times as long as wide, 1.9 times as long as pronotum; ground scales on disc about as wide as long, erect bristles much more slender (each about eight times as long as wide), separated within a row by length of a bristle; declivity steeper, a bit more narrowly impressed.

Distribution: Chile.

Type material: The female holotype was taken at Banos de Cauquenes, Rancagua, E.P. Reed. The holotype is in the U.S. National Museum, Washington.

Xylechinus squamiger Schedl

Xylechinus squamiger Schedl, 1979:60. Holotype ♂; Cordoba, Dep. de Calamuchita, El Sauce, Argentina; MACN, Buenos Aires (References in Wood & Bright c1992:119)

Diagnosis: Distinguished from *imperialis* (Schedl) by the smaller size; by the stouter body; and by an entirely different sculpture of the elytra and elytral vestiture.

Male: Length 2.0 mm, about 1.8 times as long as wide; color dark brown, pronotum almost black, vestiture pale. Frons moderately concave from epistoma to upper level of eyes on median three-fourths, central area smooth, shining, becoming closely, deeply, rather coarsely punctured toward margins; median line on lower half with a fine carina; vestiture of fine, moderately long, inconspicuous hair on all margins. Pronotum 0.83 times as long as wide; surface smooth, shining, punctures rather coarse, deep, close, spaced by less than half diameter of a puncture, smaller near anterior margin; vestiture sparse, hairlike. Elytra 1.1 times as long as wide, 1.4 times as long as pronotum; basal margin of each elytron armed by 11 coarse crenulations; striae narrowly, modestly impressed, punctures rather small, partly to mostly obsolete; interstriae almost four times as wide as striae, shining, with small, confused punctures, punctures bearing erect setae very feebly granulate. Declivity occupying slightly less than posterior half, rather steep, basically convex except shallowly sulcate between left and right

interstriae 3; interstriae 1 and 2 slightly impressed, unarmed, 3 slightly elevated, armed by a uniseriate row of about seven, moderately large, sharply pointed denticles; interstriae 4, 6, 8, and 9 unarmed, 5 and 7 each with one or two small denticles. Vestiture of fine, moderately abundant hair on most of disc, becoming scalelike on declivity, each scale rather short, four to six times as long as wide; erect rows of bristles not evident.

Distribution: Argentina: Cordoba, Dep. de Calamuchita, El Sauce.

Notes: According to the original description, this species was based on the male holotype that was deposited in MACN, Buenos Aires (publication), but a holotype is also at NHMW, Wien (see Wood & Bright c1992:3). The original description was probably based on the specimen at NHMW, Wien. The above treatment was based on the Wien specimen.

Xylechinus imperialis (Schedl)

Plate V

Xylechinus imperialis (Schedl), 1958:39 (*Pseudochramesus*). Syntypes ♂; Buenos Aires, Tigre, Argentina; NHMW, Wien (Synonymy and references in Wood & Bright c1992:116)

Xylechinus calvus Schedl, 1979:60. Holotype ♂; Buenos Aires, Pilar Island, Argentina; NHMW, Wien

Diagnosis: Antennal club more strongly flattened, slightly asymmetrical; pronotum larger; its vestiture almost all hairlike; elytra sexually dimorphic; all interstriae armed by tubercles in female, male declivity with interstriae 3 and base of 1 moderately elevated and armed by denticles, 2 impressed and unarmed.

Male: Similar to female except upper third of interstriae 1 on declivity elevated and armed by coarse denticles, lower 1 and all of 2 and 4 impressed, unarmed, 3 moderately elevated and coarsely armed, lower elevated area less extensive but higher and armed.

Female: Length 2.1–2.6 mm, 2.1 times as long as wide; color dark brown, vestiture 40 percent dark, 60 percent pale. Frons broadly convex, rugose-reticulate above eyes, smooth, shining below, punctures fine, close, deep; vestiture hairlike, fine, short, inconspicuous. Pronotum 0.85 times as long as wide; widest at base, sides convergently arcuate from base to anterior margin, constriction not evident; unarmed by asperities; surface reticulate, punctures shallow, close, moderately coarse; vestiture rather short, hairlike, a bit stouter in posterolateral areas. Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; three crenulations on basal row in humeral (lateral) area unusually coarse; many submarginal crenulations at bases of interstriae 2–3; striae moderately impressed, punctures small, deep, close; interstriae three times as wide as striae, punctures small, deep, confused, each bearing a scalelike seta (slender, pointed on disc, broadly scalelike toward declivity), also armed by many small, confused, narrow, acutely elevated crenulations, becoming uniseriate toward declivity, each tuberculate crenulation about equal in width to one-fifth width on an interstriae. Declivity rather steep, more or less broadly

convex; striae 1, 2, and 3 ending about one-third declivital length before apex, interstriae 3 elevated almost from base and joining large elevation on lower third extending from suture to apex of 7, tubercles uniseriate, continued to elevated area; scalelike vestiture abundant, each scale as wide as long.

Distribution: Argentina: Buenos Aires, Tigre; Buenos Aires, Pilar Island; San Salvador de Jujuy, 21-X-1968, C.W. & L. O'Brien; RA, Tucuman, 24-IV-1955, R. Golbach; Salta, Los Toldos, 19-21-II-1960, 2400 m, R. Golbach.

Notes: The above was based on 1 female and 2 male specimens. I compared 1 male directly to the holotypes of *Pseudochramesus imperialis* Schedl and *Xylechinus calvus* Schedl.

Xylechinus minor Eggers

Xylechinus minor Eggers, 1928:84. Holotype ♀?; Sao Paulo, Brazil; on loan to NHMW, Wien from USNM, Washington (References in Wood & Bright c1992:116)

Diagnosis: Distinguished from *spathifer* Schedl by the smaller size; by the hairlike setae on the elytral disc; and by details in sculpture of the elytral declivity.

Female (?): Length 1.7 mm, 2.1 times as long as wide; color brown, prothorax darker. Frons rather narrowly flattened from epistoma to upper level of eyes; reticulate-granulate on at least upper areas, punctures obscurely indicated; a partial median carina on lower half (visible only in part on type); vestiture of fine, short, sparse hair, inconspicuous. Pronotum 0.77 times as long as wide; pronotum surface granular, punctures not evident; vestiture of fine, short, moderately abundant hair. Elytra 1.5 times as long as wide, 2.2 times as long as pronotum; striae slightly impressed, punctures small, deep; interstriae almost twice as wide as striae, shining, each with a central row of rounded tubercles, punctures minute, obscure. Declivity convex, moderately steep; striae 1 to 4 more strongly, more narrowly impressed than on disc; interstriae shining, punctures more numerous, more clearly indicated, 1 and 3 with tubercles smaller than on disc, reduced in size toward apex, 2 and 4 without granules or tubercles. Vestiture on basal half of disc of fine, short, rather abundant interstitial hair in ground cover, becoming subplumose to scalelike on posterior disc and declivity, each interstriae with a central row of slightly longer, erect hair, each seta almost equal in length to one-third of distance between rows, separated within a row by one and one-half or more times length of a seta.

Distribution: Brazil: Sao Paulo.

Notes: The above treatment was based on the holotype, presumably a female, of *Xylechinus minor* Eggers.

Sinophloeus porteri Brethes, n. comb.

Sinophloeus porteri Brethes, 1922:434. Holotype, sex ?; Province de Cautin, Chile; Brethes Collection at MACN, Buenos Aires (Synonymy and references in Wood & Bright c1992:105).

Xylechinus spathifer Schedl, 1955:256. Lectotype ♀?; Laguna de Malleca, Prov. Malleca, Chile, 900 m; NHMW, Wien, designated by Wood 1985:270 (Synonymy and references in Wood & Bright c1992:118). *New synonymy*
Pteleobius lomatiae Schedl, 1975:2. Holotype ♂; Nahuel Huapi National Park, Argentina; NHMW, Wien. *New synonymy*

Diagnosis: Distinguished from *minor* Eggers by the larger size; by the continuation of scalelike ground vestiture almost to bases of elytra; by the scalelike erect interstitial bristles; and by sculpture of the pronotum.

Male: Length 2.3 mm, 2.2 times as long as wide; color black, vestiture rather pale. Frons essentially concave, except feebly planoconcave on upper half in median area; smooth, brightly shining; punctures fine, sparse in central area, more numerous and slightly larger toward margins; lower half with a moderately strong carina; vestiture of moderately abundant, rather long, fine hair; vestiture rugose-reticulate. Pronotum 0.80 times as long as wide; surface shining, punctures large, moderately deep, very close, of irregular shape, interspaces equal to less than one-fourth diameter of a puncture. Elytra 1.5 times as long as wide, 2.1 times as long as pronotum; striae moderately impressed; interstriae slightly less than twice as wide as striae, shining, small punctures bearing ground setae distinctly, finely tuberculate, those of erect setae in central rows more strongly tuberculate. Declivity broadly convex, rather steep; interstriae almost smooth, except each with a central row of small, rounded tubercles. Vestiture with ground cover of numerous hairlike setae on disc, less numerous on declivity, and central rows of erect scales, each almost twice as long as ground setae, each widest near its apical end, about four to six times as long as wide.

Distribution: Chile: Prov. Malleca, Laguna de Malleca, 24-I-1946, 900 m, "Huechel" log, and Prov. Curico.

Host: *Lomatia hirsuta*.

Notes: The above treatment was based on the lectotype of *Xylechinus spathifer* Schedl, a male, and on 14 other specimens.

Xylechinus freiburgi Schedl

Xylechinus freiburgi Schedl, 1972:56. Holotype ♂; New Freiburg [Island], Brazil; NHMW, Wien (References in Wood & Bright c1992:115)

Diagnosis: Distinguished by the stout body and broadly convex, unique elytral declivity; and by the absence of a median tubercle or carina on the frons.

Male: Length 2.1 mm, 1.9 times as long as wide; color very dark brown (vestiture abraded on type). Frons broadly planoconcave from epistoma to upper level of eyes; entire surface rugose-reticulate, punctures minute, moderately abundant; vestiture of coarse, rather short, moderately abundant setae (badly abraded on type); without any indication of a median tubercle or carina. Pronotum 0.90 times as long as wide; surface rugose-reticulate, punctures small, shallow, of irregular shape; vestiture of moderately abundant scales, each about twice as long as wide (badly abraded and incrustated on

type). Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; striae weakly impressed, punctures deep, coarse (except smaller toward base; interstriae as wide as striae, almost smooth, shining, punctures minute, moderately abundant, confused. Declivity broadly convex, steep; interstriae 1 distinctly elevated, 2 weakly impressed, 3 feebly elevated; striae 1 moderately, 2 weakly impressed, punctures rather strongly reduced in size from base toward apex; interstriae 4 to 6 (perhaps others) with obscure rows of very small granules near base. Vestiture mostly abraded on type, apparently of ground cover of scales (some pale, some tan), each about twice as long as wide on disc, only slightly longer than wide on declivity, and central rows of erect, slender bristles, each apparently one-half (disc) to two-thirds (declivity) as long as distance between rows, spaced within a row by length of a bristle.

Distribution: Brazil: Nova Friburgo (Rio de Janeiro).

Notes: The above treatment was based on the holotype of *Xylechinus freiburgi* Schedl, presumably a male.

Xylechinus nahueliae (Schedl), n.comb.

Xylechinus nahueliae (Schedl), 1979:59 (*Phthorophloeus*). Holotype ♀; Nahuel Huapi National Park, Argentina; NHMW, Wien (References in Wood & Bright c1992:225)

Diagnosis: Distinguished from *freiburgi* Schedl by the much more strongly, narrowly impressed frons above the level of the antennal insertions.

Male: Length 1.7–2.1 mm, 2.2 times as long as wide; color very dark brown, scales variegated, pale and dark. Frons broadly impressed from epistomal margin to level of antennal insertion, rather strongly impressed on median half from level of antennal insertions to upper level of eyes; surface shining, very finely, rather closely punctured on lower half, becoming rugose-reticulate above concavity; vestiture rather sparse, of coarse rather long hair mostly in lateral areas. Pronotum 0.74 times as long as wide; anterolateral areas with several small asperities; surface shining, punctures fine, irregular, close; vestiture scalelike, most scales about 4 times as long as wide, a few on anterior disc up to 8 times as long as wide. Elytra 1.5 times as long as wide; bases of interstriae 2 to 3 with a total of seven submarginal crenulations; striae not impressed, punctures rather coarse, deep; interstriae slightly wider than striae, almost smooth, shining, a central uniseriate row bearing erect setae, smaller punctures at margins bear ground setae. Declivity rather broadly convex, steep; interstriae 1 weakly elevated; sculpture about as on disc. Vestiture of suberect ground setae, each about twice as long as wide; erect bristles in uniseriate rows, each about 6 times as long as wide, each about half as long as distance between rows (irregular), spaced within a row by length of a bristle.

Female: Similar to male except frons irregularly convex; crenulations on pronotum distinctly larger.

Distribution: Argentina: Nahuel Huapi National Park, 15-X-1971, K. Naumann.

Notes: The above treatment was based on the female holotype, male allotype, and 1 female and 1 male paratype of *Phthorophloeus nahueliae* Schedl.

Xylechinus aconcaguensis Wood, n. sp.

Xylechinus aconcaguensis Wood: Holotype ♀; 10 km SE Zapallar, P. Aconcagua, Chile; USNM, Washington, designated below

Diagnosis: Pronotum unarmed by asperities; striae punctures on disc rather coarse, very close, interstriae only slightly wider than striae; interstitial scales slender; pronotal punctures dense, very close.

Female: Length 2.4 mm, 2.2 times as long as wide; color dark brown, scales 20 percent dark, 80 percent pale. Frons moderately convex, somewhat impressed above weakly elevated epistoma; a coarse, acutely pointed tubercle at center of frons; surface reticulate on upper half, becoming almost smooth below, punctures fine, partly obscured by rather stout, moderately long setae. Pronotum 0.90 times as long as wide; widest at base, sides convergently arcuate to weak constriction on anterior fourth; surface unarmed by asperities, densely, rather coarsely punctured, punctures separated by less than one-fourth diameter of a puncture; vestiture of scales, each scale about 4 times as long as wide (mostly pale, few dark). Elytra 1.7 times as long as wide, 2.3 times as long as pronotum; bases of interstriae 2–4 armed behind basal row by about 20 rather coarse, submarginal crenulations; striae punctures rather coarse, deep, spaced within a row by less than half diameter of a puncture; interstriae about one and one-half times as wide as striae, almost flat, confused punctures very small; vestiture of abundant scales in ground cover, each scale slender and about 4 times as long as wide, erect bristles in central rows slightly more slender than scales but only slightly longer (less than 1.5 times). Declivity steep, convex; only feebly, indistinctly impressed between left and right interstriae 3; interstriae 2 narrowed, apparently obsolete near apex; scales apparently reduced in size and number.

Distribution: Chile (Aconcagua).

Type material: The female holotype was taken 10 km SE Zapallar, P. Aconcagua, Chile, 23-XI-1967, C.W. & L. O'Brien. The holotype is in the U.S. National Museum, Washington.

Xylechinus vittatus Schedl

Xylechinus vittatus Schedl, 1966:100. Holotype ♂?; Chile; NHMW, Wien (References in Wood & Bright c1992:119)

Diagnosis: Distinguished by the comparatively large size; by the large, dense scales on pronotum and elytra; and by the rather strongly elevated declivital interstriae 3 that is ornamented by an abnormal profusion of scale-like setae.

Male (?): Length 2.6 mm, 2.2 times as long as wide; color dark brown, an abundance of pale and dark scales.

Frons broadly flattened above and below, a slight summit dividing frons transversely, a low median tubercle just above middle, with a low median carina extending from tubercle to above upper level of eyes; surface apparently subreticulate, with numerous small punctures; surface largely concealed by abundant, short, coarse setae. Pronotum 0.80 times as long as wide; surface apparently smooth, shining, with numerous fine, close punctures of various sizes; vestiture of numerous scales concealing most of surface; scales recumbent, each as wide as long, intermixed with less abundant, slightly longer, suberect, slender setae, setae forming a variegated pattern of pale and tan to brown scales. Elytra 1.4 times as long as wide, 2.0 times as long as pronotum; striae not impressed, punctures rather small, close, deep; interstriae about three times as wide as striae, surface smooth, shining, punctures minute, numerous, confused. Declivity basically convex except moderately sulcate on median one-third, rather steep; interstriae 3 rather broadly elevated on middle third, more narrowly, weakly elevated on upper one-third. Interstitial vestiture on disc of abundant scales, each slightly longer than wide, erect bristles almost twice as long as ground scales, rather stout; setae on middle one-third of interstriae 3 with scales erect and unusually dense; scales forming a variegated pattern of pale, tan, and brown.

Distribution: Chile: "867."

Notes: The above treatment was based on the holotype of *Xylechinus vittatus* Schedl, presumably a male.

Xylechinus declivis Wood, n. sp.

Xylechinus declivis Wood: Holotype ♀; 18 km W Rungue, P. Santiago, Chile, 4700 ft.; USNM, Washington, designated below

Diagnosis: Pronotum unarmed by asperities; striae punctures on disc small, spaced within a row by diameter of a puncture, interstriae twice as wide as striae; interstitial scales almost as wide as long; pronotal punctures much smaller, not as close.

Female: Length 2.2 mm, 2.3 times as long as wide; color dark brown, scales 40 percent dark, 60 percent pale. Frons feebly convex, almost flat on lower half, with areas of reticulation on upper half, somewhat smoother below; a very weak median carina on upper half; vestiture of moderately abundant, stout, almost scalelike setae; epistoma very weakly elevated. Pronotum 0.84 times as long as wide; widest at base, sides arcuately convergent to feeble constriction on anterior fourth; surface unarmed by asperities, obscurely reticulate, punctures rather fine, distinct, spaced by half to full width of a puncture; vestiture of abundant scales, each scale slightly longer than wide, about 40 percent dark, 60 percent pale. Elytra 1.7 times as long as wide, 2.2 times as long as pronotum; submarginal crenulations behind basal row minute to obsolete on interstriae 2–4; striae punctures small, deep, spaced within a row by half to full diameter of a puncture; interstriae twice as wide as striae,

weakly convex, smooth, shining, with numerous close, confused punctures; vestiture of ground cover of scales, each scale as wide as long, and erect bristles, each bristle about 6 times as long as wide and slightly less than twice as long as ground scales. Declivity rather steep, weakly impressed between interstriae 3 (almost transversely flat), interstriae 2 narrower, obsolete before apex, 3 feebly elevated, unarmed.

Distribution: Chile (Santiago).

Type material: The female holotype was taken 18 km W Rungue, P. Santiago, 24-XII-1967, 4700 ft., C.W. & L. O'Brien. The holotype is in the U.S. National Museum, Washington.

Xylechinus variegatus (Chapuis)

Xylechinus variegatus (Chapuis), 1869:40 (*Phloeosinus*). Holotype ♂; Chili; IRSNB, Brussels (References in Wood & Bright c1992:119)

Diagnosis: Anterolateral areas of pronotum unarmed by asperities; scales on pronotum and elytra stout, almost as wide as long; female frons armed at upper level of eyes by a small, laterally compressed tubercle; declivity moderately impressed, interstriae 3 obsolete on lower third.

Female: Length 1.9 mm, 2.3 times as long as wide; color dark brown. Frons with a weak, transverse impression just above epistomal margin, almost flat to upper level of eyes; surface smooth, shining, with minute, moderately abundant punctures; a laterally compressed, moderately large tubercle at or just below upper level of eyes. Pronotum about 0.96 times as long as wide; sides weakly arcuate, converging cephalad from base; anterolateral areas unarmed; surface shining, with moderately abundant micropunctures, setiferous punctures small; vestiture of ground cover of scales, each scale almost as wide as long, a few slender bristles on disc little longer than scales. Elytra 1.6 times as long as wide, 2.0 times as long as pronotum; bases of interstriae 2–3 with about six weak, submarginal crenulations; striae not impressed, punctures rather coarse, deep, close; interstriae as wide as striae, shining, each with a row of small scales (each scale as long as wide) on each margin, a central row of erect bristles (each less than twice as long as scales, each four to six times as long as wide), punctures small, not granulate. Declivity rather steep, broadly convex, shallowly impressed between interstriae 3; striae and interstriae narrower than on disc, interstriae 2 on right elytron attaining its apex, left side narrowed, almost obsolete by apex; vestiture about as on disc.

Distribution: Chile: Valparaiso, La Campana, 9-VIII-1979, 1000 m, B. esclerell., C. Vivar T.

Notes: The above treatment was based on the male holotype and on one female of *Phloeosinus variegatus* Chapuis. The type has declivital interstriae 3 a bit more strongly convex and interstriae 2 more strongly impressed. Sexual differences probably account for the differences.

Xylechinus solervicensi Wood, n. sp.

Xylechinus solervicensi Wood: Holotype ♂; Valparaiso, La Campana, Chile; USNM, Washington, designated below

Diagnosis: Anterolateral areas of pronotum unarmed by asperities; submarginal crenulations at base of interstriae 2–5 greatly reduced to obsolete; elytral declivity steeper, moderately impressed; male frons with a strong subacute carina at upper level of eyes.

Male: Length 2.6 mm, 2.2 times as long as wide; color very dark brown, scales variegated (50 percent pale, 50 percent dark). Frons broadly, very shallowly concave from epistoma almost to upper level of eyes; a moderately strong median carina from just below to just above upper level of eyes, highest near its lower end; surface apparently shining, finely, irregularly punctured (obscured by frass), vestiture rather coarse, long, moderately abundant except absent on median area above. Pronotum 0.88 times as long as wide; sides arcuately converging from base; anterolateral areas unarmed by crenulations; surface shining, punctures fine, close, shallow; vestiture of broad, short scales, each as wide as long, a few slightly longer, slender bristles also on disc. Elytra 1.6 times as long as wide, 2.0 times as long as pronotum; bases of interstriae 2 to 3 with about three to four submarginal crenulations (almost obsolete); striae not impressed, punctures small, deep, close; interstriae three times as wide as striae, shining, confused; vestiture of ground cover of short scales, each scale about as wide as long, and central rows of erect, slender bristles, each about half as long as distance between rows, spaced within a row by length of a bristle. Declivity steep, convex; moderately impressed between left and right interstriae 3; striae 1 and 2 distinct, interstriae 2 as wide as striae, moderately impressed, 1 feebly convex; no tubercles on interstriae; erect bristles shorter than on disc.

Distribution: Chile (Valparaiso).

Type material: The male holotype was taken at La Campana, Valparaiso, Chile, 20-IV-1979, 450 m, ex Mat. xerofilo, I. Solervicens; 1 paratype is from Rio Clarillo, Cordillera, Chile, 6/7-31/X-1989, C. Gonzales. The holotype and paratype are in the U.S. National Museum, Washington.

Xylechinus huapiiae (Schedl), n. comb.

Xylechinus huapiiae (Schedl), 1979:59 (*Phthorophloeus*). Holotype ♀; Nahuel Huapi National Park, Argentina; NHMW, Wien (References in Wood & Bright c1992:222)

Diagnosis: Distinguished from *solervicensi* Wood by the smaller size; by the interstitial ground setae on the disc being longer than wide while the erect setae are about four to six times as long as wide; and by the longer, coarser, less abundant frontal setae.

Male: Length 2.0 mm, 2.2 times as long as wide; color brown, pronotum darker, scales variegated, pale and tan. Frons broadly flattened from weakly elevated

epistoma to upper level of eyes, surface smooth, shining, with rather deep, moderately close punctures of moderate size; a strong median carina on upper half with its acutely pointed summit at its lower end; vestiture of long, rather fine hair of about uniform distribution. Pronotum 0.80 times as long as wide; surface mostly smooth, shining, shallow punctures of irregular small size; without asperities, a few very fine granules in lateral areas; setae of two kinds, most scalelike, each slightly longer than wide, a few slender, about 6 times as long as wide and about equal in length to scales. Elytra 1.5 times as long as wide, 2.1 times as long as pronotum; bases of interstriae 2 to 3 with two submarginal crenulations; striae weakly impressed, punctures rather coarse, deep; interstriae slightly less than twice as wide as striae, surface smooth except for obscurely impressed, subtransverse lines, punctures very small, moderately abundant, confused. Declivity rather broadly, moderately sulcate, steep; sulcus deepest on middle half, extending from deepest point at suture to interstriae 3, ending well before apical margin, striae and interstriae sculpture about as on disc. Vestiture of ground cover of short scales, each about one to two times as long as wide; erect bristles in central interstitial rows on and near declivity, each less than twice as long as a ground scale. Setae on pronotum and elytra a mixture of pale and tan.

Female: Similar to male except tubercles on lateral areas of pronotum distinctly larger and more numerous.

Distribution: Argentina: Nahuel Huapi National Park, 15-IX-1971, K. Naumann.

Notes: The above treatment was based on the female holotype and male allotype of *Phthorophloeus huapiiae* (Schedl).

Sinophloeus porteri Brethes

Sinophloeus porteri Brethes, 1925:202. Holotype, sex?; Loncoche, Chile; not given (References in Wood & Bright c1992:118)

Several attempts to locate authentic examples of this species were not answered. The original description is quoted as follows:

“Oblongus, piceus, funiculo pedibusque obscure ferrugineis, prothorace parum transverso, anterie subconstricto, supra subdense punctato, interstitiis politis, sat dense squamoso; elytris subcylindricis, grosse punctato-striatis, esquamis brevibus biseriatum ornatis. Long.: 1.8 mm.

“Oblong, d'un noir de poix, la tete lisse, sensiblement imprimee au front entre les yeux, avec ponctuation tres fine, le bord anterieur de l'epistome avec squamules relativement longues et fauves. Antennes avec la massue allongee, plus longue que la funicule, ses articles subegaux. Prothorax a peine plus large que long, progressivement retreci vers l'avant, sa surface assez densément ponctuee les espaces lisses; des squamules courtes et obscures assez denses, meles de quelques-unes fauves. Ecusson triangulaire transverse, avec ecailles fauves.

Elytres paralleles, de la largeur du prothorax et deux fois plus longues, ponctuees-striees, les points forts, les espaces luisants, couverts de squamules fauves en series de deux; declivite posterieure arrondie, sans sculpture speciale. Coxas anterieures non contigues; metasternum lisse, finement ponctue, une impression longitudinale en son milieu; premier segment de l'abdomen finement chagrine et luisant, aussi long que les deux segments suivants.

Note: See pp. 51, 53, and 57.

“Mr. le Dr. Porter recueillit cette espece a Loncoche [Cautin], en Febrier 1917” [Cautin, Chile].

GENUS *HYLURGUS* LATREILLE

Hylurgus Latreille, 1807:274. Type-species: *Bostrichus ligniperda* Fabricius, monobasic (References in Wood & Bright c1992:119)

Diagnosis: Metepisternal setae hairlike; antennal funicle 6-segmented; procoxae contiguous; pronotum as long as wide, only feebly constricted anteriorly; erect interstitial setae confused, abundant; a short median carina on lower frons.

Description: Frons not sexually dimorphic, a short median carina on lower fourth; antennal funicle 6-segmented, club conical, feebly flattened; pronotum as long as wide, weakly constricted anteriorly; elytra with erect setae confused, abundant.

Distribution: Three species are known. Two occur naturally in Europe, Asia Minor to northern Asia, and northern Africa; 1 occurs in northern India.; 1, *ligniperda*, has been introduced through commerce to Australia, South Africa, and South America.

Biology: All species attack *Pinus* spp. and are monogynous. Their monoramous parental galleries are made in the thick bark at the base of host trees.

Hylurgus ligniperda (Fabricius)

Plate V

Hylurgus ligniperda (Fabricius), 1787:37 (*Bostrichus*). Holotype, sex?; Germania; UZMC, Copenhagen (Synonymy and references in Wood & Bright c1992:119–122)

Bostrichus elongatus Herbst, 1793:117. Syntypes, sex?; Deutschland; not located

Hylesinus flavipes Panzer, 1795:61. Syntypes, sex?; article not seen; not located

Hylurgus longulus Kolenati, 1846:38. Syntypes, sex?; Shamlogh, territorii Airum, montis Kaepe-Dagh, provinciae Transcaucasicae Elizabethopol; not located

Male: Similar to female except frontal carina higher; hair on elytral declivity conspicuously longer and usually more abundant.

Female: Length 4.5–5.4 mm, 2.6 times as long as wide; color light brown to almost black (dependent on degree of maturity). Frons convex from vertex to weak constriction at level of antennal insertion, then feebly subinflated below, a rather strong median carina from epistoma almost to level of antennal insertion, its upper end more strongly, tuberculately elevated; surface shining, densely, coarsely punctured, becoming closely, finely

tuberculate on lower fourth; vestiture of sparse, fine, inconspicuous hair; antennal club conical, segment 1 occupying basal half, sutures straight. Pronotum 0.98 times as long as wide; widest at base, sides weakly, convergently arcuate on basal three-fourths, feebly constricted on anterior third; surface shining; punctures very close, rather coarse, deep; vestiture of short, sparse hair, longer at sides. Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; striae feebly impressed, punctures moderately large, deep; interstriae about twice as wide as striae, densely armed by acute crenulations, each crenulation at base about half as wide as an interstriae, smaller toward declivity (about one-fourth as wide as an interstriae), their posterior slope steep, each marked by a setiferous puncture; declivity very steep, basically convex, interstriae 2 rather strongly impressed, interstitial tubercles reduced in size and numbers, absent on 2; vestiture of abundant, confused hair, equal in length on disc to width of an interstriae, twice as long on disc and more abundant.

Distribution: Native to Europe, Asia, and northern Africa. Introduced through commerce to South America, Australia, New Zealand, and South America (Argentina, Brazil, Chile, Paraguay, Uruguay) in *Pinus* plantations.

Argentina: Oral report, not confirmed.

Brazil: Gravata, Rio Grande do Sul, 1-VIII-1991, *Pinus taeda* stand ethanol trap, A. Phulatka (Schoenherr & Pedrosa-Macedo 1981); Telemaco Borba, Parana, 7-XI-2003, Klabin Papel e Cellulose forest, sulcatol + ethanol trap, C.A.H. Flechtmann; “Code 026, R.A. Beaver,” Brazil.

Chile: Melipilla, Curacavi, X-1988, J. Solervicens; San Carlos, 29-IX-1985, pino-cortez, SAG; Valparaiso, II-1988, 20-III-1988, Trampa, J. Godoy; Piedra Comadres, 12-16-I-1991, Roitman (also Ciesla 1988, unpublished).

Paraguay: Cited in literature? (oral report, not confirmed).

Uruguay: “Uruguay” (Wood & Bright c1992:119).

Hosts: *Pinus* spp. (in Europe and Asia also in *Picea*, *Larix*, and *Pseudotsuga*).

Biology: Phloeophagous in fresh stumps, slash, and the lower bole of larger trees under thick bark. Three generations each year were reported by Cogollor (1991, Pest Risk Importation Assessment). Adults may be found in Chile during any month of the year.

Notes: The above treatment was based on 17 European specimens that were identified by Pfeffer, Eggers, and Schedl, and on 4 from Chile.

GENUS *HYLURGONOTUS* SCHEDL

Hylurgonotus Schedl, 1952:448. Type-species: *Hylurgonotus brunneus* Schedl = *Hylurgus tuberculatus* Eggers, monobasic (References in Wood & Bright c1992:186)

Diagnosis: Metepisternal setae hairlike (bifid in on1 species); antennal funicle 7-segmented; protibia armed

on apical margin by 3 or 4 socketed teeth; male frons shallowly to strongly impressed.

Description: Frons sexually dimorphic, male frons shallowly to strongly impressed, female usually convex; antennal funicle 7-segmented, club conical, segment 1 occupying basal one-fourth to one-third; pronotum unarmed by asperities; elytral sculpture simple; protibia armed by 3 or 4 socketed teeth; vestiture hairlike, except 1 species (*tuberculatus*, with ground cover of scales on elytral declivity). Closely allied to *Pachycotes* of Australia and New Zealand.

Distribution: Four species occur in southern South America.

Biology: Largely unknown. All species infest *Araucaria* spp. Their gallery systems are apparently partly in phloem and partly in xylem tissues (Schedl 1966:43). The tunnels are stained black by fungi, but the extent to which they have adopted the xylomycetophagous habit is not clear. They apparently do not feed directly upon the spores. The closely allied *Pachycotes* are apparently, exclusively xylophagous.

Key to the Species of *Hylurgonotus*

- 1. Body more slender, more than 2.4 times as long as wide; protibia armed by four socketed teeth; pronotum surface between punctures rather strongly reticulate; basal segment of conical antennal club longer, occupying about one-third of club length 2
- Body stouter, 2.0–2.2 times as long as wide; protibia armed by 3 socketed teeth; pronotum surface between punctures smooth, shining; basal segment of antennal club shorter, occupying one-fourth length of club, club distinctly flattened 3
- 2(1). Mature color brown; declivital interstriae 2 constricted, obsolete before apex, impressed, 1 and 3 convex, 1, 3, 5–7 armed by pointed tubercles in female, 1–3 without tubercles in male, lateral areas devoid of coarse spines; declivity with ground cover of small scales; *Araucaria araucana* Chile; 3.6–4.2 mm *tuberculatus* (Eggers)
- Mature color dark black; declivital interstriae 1–4 about equally convex, smooth, shining, with a few inconspicuous, minute tubercles, basal margin of declivity with one conspicuous tubercle each on interstriae 1–6, lateral margin from sutural apex to apex of 7 armed by a row of a total of four large, pointed, almost spinelike tubercles; declivity almost glabrous, a few minute, hairlike setae in lateral areas; Chile; 3.5–4.4 mm *armaticeps* Schedl
- 3(1). Body smaller, stouter, 2.0 times as long as wide; elytral declivity usually with large, conical tubercles on all interstriae, except absent on 2 and (rarely) 4 in some males; interstitial tubercles mostly closer, coarser; Chile; 2.9–3.6 mm *solidus* (Schedl)
- Body larger, 2.2 times as long as wide; elytral declivity with interstriae 1, 2, and 4 in male, 2 and 4 in female without tubercles, tubercles mostly smaller, not as close, on disc more nearly rounded; Chile; 3.5–4.6 mm *antipodus* (Eggers)

Hylurgonotus tuberculatus (Eggers)

Plate VII

Hylurgonotus tuberculatus (Eggers), 1942:13 (*Hylurgus*). Holotype ♀; Bolivia oder Chile; Hamburg Museum, lost (Synonymy and references in Wood & Bright c1992:187)

Hylurgonotus brunneus Schedl, 1952:448. Holotype ♂; Gob. Rio Negro, Argentina; NHMW, Wien

Diagnosis: Antennal club conical, basal segment largest; pronotum reticulate; protibia armed by 4 socketed teeth; color brown; elytral declivity sexually dimorphic, with ground cover of scales.

Male: Similar to female except frons smooth, shining, punctures much smaller, less abundant, slightly impressed (flat transversely, weakly concave longitudinally), median carina absent, transverse carina very obscure; declivital tubercles absent on interstriae 1–3 and smaller on 4–9.

Female: Length 3.6–4.2 mm, 2.5 times as long as wide; color brown. Frons convex from epistoma to vertex; obscurely constricted on anterior third, surface weakly reticulate, punctures replaced by uniformly distributed, subacute tubercles, a moderate, subacute median carina on lower half, a low transverse carina above upper level of eyes on median fourth; hairlike vestiture fine, short, inconspicuous. Pronotum as long as wide, unarmed; surface reticulate, punctures rather large, coarse, moderately deep; glabrous. Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; striae rather narrow, moderately impressed, punctures rather small, shallow, moderately, not clearly impressed; interstriae almost twice as wide as striae, moderately convex; surface obscurely subreticulate, numerous confused punctures obscurely indicated, a central row of them subtuberculate near base, becoming moderately tuberculate toward base of

declivity; declivity rather steep, basically concave but bisulcate, striae narrower, punctures larger, deeper; interstriae 1 and 3 moderately elevated, 2 impressed, constricted and eliminated before apex, each bearing a row of rather large, pointed tubercles on all interstriae except lower two-thirds of 2 (confused on 3); vestiture consisting of fine, short, sparse to absent hair on disc, of short, moderately abundant scales on declivity, each scale two to four times as long as wide, tubercles each bearing a hairlike bristle.

Distribution: Argentina to southern Chile.

Argentina: "Gob., Rio Negro."

Bolivia: Cited by Bright & Skidmore (1994:35).

Chile: Caramavida, 25-I-1953, L.E. Pena; Cautin, Conguillio, 6-II-1979, J. Solervicens; Cautin, Villarica, 20-VIII-1976, R. Genestier; Cherquenco, I-1954, L.E. Pena; Lago Icalma (Sudchile); Crest of Nahuelbuta, W of Angol, 29-I-1951, 1800 m, E.S. Ross; Lago Tromen (Sudchile); Malachuella/Lonquimay (Sudchile), W. Ruhm; Malleco, Nahuelbuta, 4-II-1980, J. Solervicens; Prov. Malleco, Pemehue, 17-I-1946, 1650 m, and 18-I-1946, 1550 m, G. Kushel; Pemehue, I-1896; Pininahuel, 23-VI-1954, L.E. Pena.

Hosts: *Araucaria araucana*.

Biology: Xylophagous, galleries apparently without ambrosial fungus (Schedl 1966:42–43).

Notes: The above treatment was based on 14 specimens. I compared 1 male to the male holotype of *brunneus* Schedl. The unique female holotype of *Hylurgus tuberculatus* Eggers was destroyed with the Hamburg Museum, but the species is easily recognized from the original description as a senior synonym of *brunneus*.

Hylurgonotus armaticeps Schedl

Hylurgonotus armaticeps Schedl, 1955:257. Holotype ♀; Llama, Cautin, Chile; NHMW, Wien (References in Wood & Bright c1992:187)

Diagnosis: Antennal club conical, basal segment largest; pronotum reticulate; protibia armed by 4 socketed teeth; mature color dark black; elytral declivity subglabrous, with 4 large spines on lateral margin, a transverse row of tubercles on interstriae 1–4 at basal margin.

Female: Length 3.5–4.4 mm, 2.4 times as long as wide; color black. Frons convex from epistoma to vertex; surface smooth, shining, rather coarsely, deeply, very closely punctured on upper half, more finely, deeply, less closely punctured on lower half; epistomal lobe with a very short, subcarinate median elevation; glabrous. Pronotum 0.91 times as long as wide, moderately constricted on anterior third, sides on basal half subparallel; surface obscurely reticulate, punctures rather coarse, moderately close on basal two-thirds, distinctly smaller anteriorly; glabrous. Elytra 1.4 times as long as wide, 1.7 times as long as pronotum, striae moderately impressed, punctures deep, rather small, spaced within a row by twice diameter of a puncture; interstriae almost twice as wide as striae, convex, smooth, shining, punc-

tures small, confused, moderately close, with no tubercles between basal subcrenulations and base of declivity; base of declivity rather abrupt, basal margin of each interstriae (1–4) armed by one obtusely pointed, moderately large tubercle; declivity very steep, broadly convex, interstriae 1–3 equally convex and unarmed, 2 ending before apex; a row of four very coarse, pointed tubercles on lateral margin from sutural apex to apex of interstriae 7, interstriae 4 with two small tubercles; glabrous except for a few fine hairlike setae in lateral areas.

Distribution: Chile: Llama, Cautin; Lonquimay, 10-11-I-1962, R.L. Usinger.

Hosts: *Araucaria* sp.

Notes: The above was based on 3 females, 1 of which I compared to the holotype of *Hylurgonotus armaticeps* Schedl.

Hylurgonotus solidus (Schedl)

Plate VI

Hylurgonotus solidus (Schedl), 1967:6 (*Blastophagus*). Holotype ♀; Nahuelbuta (W), Arauco, Caramavida, 720–1000 m, Chile; ZSSM, Munchen (References in Wood & Bright c1992:187)

Diagnosis: Antennal club distinctly flattened, segment 1 shorter, subequal in length to 2; pronotum with spaces between punctures smooth, shining; protibia armed by 3 socketed teeth; elytral declivity armed by closely set tubercles on all interstriae in female, some males with parts or all of 2 and 4 unarmed.

Male: Similar to female except frons shallowly concave from epistoma to upper level of eyes, punctures on lower fourth larger, deeper; discal crenulations lower, rounded, longitudinally thicker; declivital tubercles on interstriae 2 and 4 reduced in size and number, often partly to entirely obsolete; vestiture shorter, less abundant.

Female: Length 2.9–3.6 mm, 2.0 times as long as wide; color brown. Frons modestly convex on middle third, a distinct, transverse impression on lower third; surface shining, punctures mostly small, irregular, most not sharply impressed; an obscure median crest on middle third; vestiture sparse, hairlike, inconspicuous, a few coarse bristles in lateral areas. Pronotum 0.8 times as long as wide; widest at base, sides arcuately converging to moderate constriction on anterior third; surface smooth, shining, punctures irregular, very small to medium size, not uniformly distributed; subglabrous, a few large bristles in lateral areas. Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; striae not impressed, punctures irregularly obsolete to minute and obscurely impressed; interstriae about three times as wide as obscure striae, coarsely, closely crenulate, most crenulations as wide as interstriae, acute, steeper posterior face of crenulations often marked by a fine puncture; crenulations narrower and tuberculate toward declivity; declivity very steep, broadly convex; declivital interstriae armed by pointed tubercles, smaller and

more widely spaced toward apex, striae punctures minute when present; vestiture restricted to rows of erect, long setae, hairlike on disc, bristlelike on declivity.

Distribution: Chile: Caramavida, 1-I-1954, L.E. Pena; Sierra de Nahuelbuta W of Angol, 1200 m, 2-I-1951, E.S. Ross & Michelbacher.

Hosts: *Araucaria araucana* (Wood & Bright c1992:187).

Notes: The above treatment was based on 7 specimens. I compared 1 of the females to the holotype of *Blastophagus solidus* Schedl.

Hylurgonotus antipodius (Eggers)

Plate VI

Hylurgonotus antipodius (Eggers), 1942:14 (*Blastophagus*). Holotype ♂; Valdivia, Chile; Hamburg Museum, lost (References in Wood & Bright c1992:187)

Diagnosis: Antennal club distinctly flattened, segment 1 subequal in length to 2; pronotum with spaces between punctures smooth, shining; protibia armed by 3 socketed teeth; elytral declivity with interstriae 1, 2, and 4 unarmed in male, 2 and 4 in female, others with pointed tubercles, lateral margin of declivity without large spines.

Male: Similar to female except frons rather strongly, broadly concave from near epistoma almost to to upper level of eyes; discal interstitial crenulations reduced to small irregularities, except larger, tuberculate near base of declivity; declivital interstriae 1, 2, and 4 unarmed, 3 and 5 with fewer, larger tubercles; a few very long, hairlike setae on sides especially near declivity.

Female: Length 3.5–4.6 mm, 2.2 times as long as wide; color brown. Frons convex from just above epistoma to upper level of eyes; surface reticulate, punctures fine, moderately close; vestiture sparse, hairlike, inconspicuous, a few long, coarse hairs in lateral areas. Pronotum 0.87 times as long as wide; widest on moderately arcuate sides of basal half, moderately constricted on anterior half; surface smooth, shining, punctures rather small, close, irregular in spacing; largely glabrous, a few coarse, hairlike setae in lateral areas. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures small, deeply, regularly impressed; interstriae three or more times as wide as striae, smooth, shining, crenulations almost uniseriate, almost as wide as interstriae, spaced within a row by half to full width of an interstriae, not as high as *solidus*, subacute. Declivity convex, moderately steep; crenulations reduced in width to pointed tubercles; tubercles absent on interstriae 2 and 4 and reduced in size and number on lower half of 1 and 3, subglabrous, a few short, hairlike setae scattered irregularly.

Distribution: Chile: Alto Caicupil, 7-I-1954, L.E. Pena; Arauco, Cord. Nahuelbuta, Caramavida, 1-6-I-1954, 1200–1400 m, L.E. Pena; Butamala, 23-I-1954, L.E. Pena; Malleco Galletua, 8-II-1991, *Araucaria araucana*, J. Solervicens; Malleco, Lonquimay, 22-XII-1956, *Araucaria*

(ramas), G. Kushel; Malleco Nahuelbuta, 7-II-1980, J. Solervicens; Valdivia, *Araucaria*, Izquierdo; Pemehue (Sudchile), Garmain; Nahuelbuta, 5-XI-1961, *Araucaria araucana*, Aste, phloem, W. Ruhm; Llama, 17-IX-1951; Cautin, Codoceo, W of Angol, 1800 m, 23-I-1951.

Hosts: *Araucaria araucana*.

Biology: Taken from the phloem of branches of the host.

Notes: The above was based on 24 specimens. I compared 1 of the males to the holotype of *Blastophagus antipodius* Eggers.

GENUS *TOMICUS* LATREILLE

Tomicus Latreille, 1802/3:203. Type-species: *Hylesinus piniperda* Fabricius, monobasic (Synonymy and references in Wood & Bright c1992:122–136)

Blastophagus Eichhoff, 1864:25. Type-species: *Hylesinus piniperda* Fabricius = *Dermestes piniperda* Linnaeus, monobasic

Myelophilus Eichhoff, 1878:400. Type-species: *Hylesinus piniperda* Linnaeus, automatic

Diagnosis: Metepisternal and elytral setae hairlike; antennal club conical, not flattened, funicle 6-segmented; procoxae moderately separated; erect interstitial setae uniseriate; frons usually with a median carina.

Description: Length 2.5–4.5 mm. Frons not sexually dimorphic, a short median carina near epistoma in most species; antennal club conical, sutures straight; pronotum unarmed by asperities or other irregularities; procoxae moderately separated, protibiae armed by 5 or more socketed teeth; elytra with striae indicated, declivity convex, steep.

Distribution: Six species occur in Europe, northern Asia, the Canary Islands, and northern Africa. One species was introduced through commerce to North America and the Philippine Islands.

Hosts: *Pinus* spp., *Picea* spp.

Biology: These monogynous, phloeophagous species form monoramous or biramous parental tunnels in the bole in moderately large to large trees. Newly emerged adults may form maturation feeding tunnels in twigs of larger trees or in the stems of nursery stock. They are capable of inflicting severe economic damage.

Notes: No species of this genus have been reported from South America. However, due to the large plantations of *Pinus* that are vulnerable to injury by these species, plantation managers should be familiar with these species and with methods of their control before they are found.

GENUS *DENDROCTONUS* ERICHSON

Dendroctonus Erichson, 1836:52. Type-species: *Bostrichus micans* Kugelann, subsequent designation by International Commission on Zoological Nomenclature 1963 (China 1963:276–278); (References in Wood & Bright c1992:136–186)

Diagnosis: Distinguished from *Tomicus* by the 5-segmented antennal funicle; by the moderately flattened

antennal club with procurved sutures; by the contiguous procoxae; and by the absence of a median frontal carina and presence of a conspicuous epistomal process.

Description: Length 2.5–9.0 mm; frons at least weakly, sexually dimorphic, epistomal process more strongly elevated in male; antennal funicle 5-segmented, club moderately flattened, sutures modestly procurved; pronotum unarmed; elytra with striae indicated, declivity convex, steep.

Distribution: Fifteen species are native to North America south to Nicaragua; 1 occurs in Europe, Asia Minor to northern Asia and Japan, and 1 occurs in China.

Hosts: *Pinus* spp., *Picea* spp., *Larix* spp., and *Pseudotsuga* sp.

Biology: These monogynous, phloeophagous species form monoramous parental tunnels in the bole of mod-

erately large to large trees. They include the most destructive insect species in pine forests known in the world.

Notes: Breeding populations of this genus introduced outside of the normal range have been found and eradicated in Israel and Japan. None have yet been found in South American plantations of coniferous trees, although *D. rufipennis* is said to have been intercepted there. Extreme vigilance must be exercised in order to detect and eradicate introduced populations of these exceedingly destructive species from South American plantations of conifers if or when an introduced population is found. Because of the extremely serious economic losses that could occur, immediate emergency action is imperative.

TRIBE PHRIXOSOMINI

Description: Frons not sexually dimorphic, often with a fine median carina; eye completely divided into separate halves; antennal scape elongate, funicle 6-segmented, club rather strongly flattened, slightly asymmetrical, unmarked by sutures (in some species) except 1 partly septate, up to 3 sutures indicated by setae (and septum in 1) in others; procoxae contiguous; tibiae armed on apical and lateral margins by several socketed denticles.

Biology: These monogynous, phloeophagous tropical species occur only in Africa and tropical America where they make bi- or triramous parental galleries. All known American species and most African species breed exclusively in hosts of the Guttiferae. Five African species have been recorded from non-Guttiferae hosts, 1 each from Euphorbiaceae, Passifloraceae, Sapotaceae, and 2 from Apocynaceae; it is not yet known if these were normal hosts, accidental or emergency hosts, or errors in host identification. Of the 22 species recorded by Wood & Bright (c1992:189–190), 13 occur in America (Central and South), 9 of which are reported from South America.

GENUS *PHRIXOSOMA* BLANDFORD

Phrixosoma Blandford, 1897:148. Type-species: *Phrixosoma rude* Blandford, monobasic (Synonymy and references in Wood & Bright c1992:189–190)

Bothryperus Hagedorn, 1909:742. Type-species: *Bothryperus psaltes* Hagedorn, monobasic

Neohylesinus Eggers, 1920:118. Type-species: *Neohylesinus quadrioculatus* Eggers, monobasic
Sphaerosinus Eggers, 1920:40. Type-species: *Sphaerosinus striatus* Eggers, monobasic

Diagnosis: The stout body, dark color, divided eye, unique antenna, and hosts distinguish this genus from all others.

Description: Length 1.6–4.0 mm, 2.0–2.3 times as long as wide; color usually black, vestiture rather pale. The sexes are similar. Frons convex, usually granular and with a fine median carina, sculpture and hairlike vestiture simple; antennal scape elongate, funicle 6-segmented, club flat, usually unmarked by sutures except part of 1 septate, some species with one to three sutures variously marked by setae. Pronotum simple, unarmed, setae hairlike; scutellum visible. Elytra with striae narrowly, rather deeply impressed, interstriae finely, closely tuberculate-crenulate; costal margin ascending behind.

Distribution: Tropical lowlands where hosts (Guttiferae) grow.

Biology: Only the bole or larger limbs of moderately large trees that have been recently felled, broken, or uprooted are infested. All known species are monogynous. Parental galleries are almost always biramous, rarely triramous in species that are normally biramous. Parental galleries may be predominantly transverse or longitudinal. Larval mines tend to be short, nondirectional, and show on peeled bark.

SCOLYTIDAE OF SOUTH AMERICA

Key to the Species of *Phrixosoma*

1. Transition in sculpture on female head at vertex abrupt, marked by an abrupt line (impressed or elevated) 2
- Transition in sculpture on female head from upper frons to vertex gradual, not marked by an abrupt line of impression or elevation 3
- 2(1). Transition from upper frons to vertex on female head obtuse, not impressed in lateral area above eye; interstitial setae on disc of very fine, confused hair; Bolivia to French Guyane; 3.2–3.6 mm *magna* Blackman
- Transition from upper frons to vertex more abrupt, distinctly, subconcavely impressed in lateral area above eye; interstitial setae on disc very stout, setae organized into three ranks on each interstriae; Mexico (Oaxaca) to Venezuela; *Rheedia edulis*, *Symphonia* sp.; 1.6–2.0 mm *minor* Wood
- 3(1). Pronotum disc smooth, shining, punctures near median area distinct, isolated, tending toward confluence laterally; setae on anterior half of elytral disc fine, hairlike, central row not longer or coarser; all setae coarser on posterior disc and declivity; setae on pronotum fine; Peru; 1.9 mm *peruviana* Eggers
- Punctures on pronotum obsolete, impressed areas mostly reticulate; interstitial setae rather coarse (except *obesa* where central row much longer) 4
- 4(3). Ground vestiture on elytral disc hairlike and central row on each interstriae erect, much longer, bristlelike, each bristle at least two-thirds as long as distance between rows; Costa Rica to Colombia; *Rheedia edulis*, *Symphonia globulifera*; 1.8–2.5 mm *obesa* Blackman
- Ground vestiture on elytral disc hairlike, stout, central row of bristles on each interstriae either not evident or shorter, stouter 5
- 5(4). Anterior margin of female pronotum in lateral area adjacent to eye with a large subquadrate, semi-transparent extension; Colombia; *Rheedia madruno*; 2.5–3.2 mm *frustrata* Wood
- Anterior margin of female pronotum in pleural area without a conspicuous extension at level of eye 6
- 6(5). Interstitial setae on disc confused, without distinct organization into ranks; punctures on pronotum disc not clearly evident 7
- Interstitial setae on disc organized into three distinct ranks on each interstriae, at least some punctures distinctly impressed on disc of pronotum 9
- 7(6). Declivital interstriae 1–3 with central tubercles largely to entirely obsolete; interstitial crenulations in disc mostly rounded (somewhat beaded); Venezuela; *Rheedia madruno*; 2.3–2.8 mm *viriosa* Wood
- Declivital interstriae 1–3 each with a row of numerous fine tubercles; discal interstitial crenulations subacute 8
- 8(7). Pronotum disc small, mostly confluent, obscure punctures (punctures not reticulate or granulate), interspaces smooth, shining (not convexly elevated into ridges); pronotal vestiture of rather fine, long hair; declivital striae 8 continuing and joining striae 3, 4 meets 7; tubercles on declivital interstriae 1–3 close, isolated, not forming an almost continuous crest; setae on declivital interstriae 1–3 confused; Brazil; 1.7 mm *brasiliensis* Schedl
- Pronotum disc with basic surface strongly reticulate, dull, punctures obsolete, interspaces smooth, shining, forming short, convex, mostly longitudinal irregular ridges; pronotal vestiture stout, shorter; declivital striae 8 ending before apex, 7 almost joining 3; declivital interstriae 1–3 with

- central tubercles small, very close, almost forming continuous crests, setae on 1–3 clearly three-ranked; Venezuela; *Rheedia madruno*; about 2.1 mm *barinensis* Wood
- 9(6). Posterior half of pronotum with most punctures confluent, spaces between punctures mostly convex, anterior third with numerous minute granules (punctures not evident); transition from all granular areas to all reticulate areas near vertex much more abrupt; Venezuela; *Rheedia madruno*; 1.5–1.7 mm *rubra* Wood
- Pronotum on posterior half smooth, shining, clearly, distinctly punctured, a few punctures confluent, many spaced by diameter of a puncture, anterior third with punctures smaller, more widely spaced, without granules; transition in sculpture from frons to vertex very gradual, shining areas intermixed with reticulation; Colombia; *Rheedia madruno*; 1.8–1.9 mm *crebra* Wood

Phrixosoma magna Blackman

Phrixosoma magna Blackman, 1943:392. Holotype ♀; Bolivia; USNM, Washington (References in Wood & Bright c1992:189)

Diagnosis: Female head with abruptly marked separation in sculpture between upper frons and vertex but not subconvexly impressed in lateral areas above eye; interstitial setae on disc of fine hair.

Female: Length 3.2–3.6 mm, 1.9 times as long as wide; color dark reddish brown (mature color?). Frons broadly, evenly convex, a very fine, low median carina on lower half; surface on type obscured by incrustation, apparently reticulate, finely, closely, shallowly punctured; vestiture of very fine, short hair. Pronotum 0.76 times as long as wide, widest near base, sides arcuately converging to broadly rounded anterior margin; densely, finely, obscurely punctured, interiors of punctures reticulate, spaces between punctures smooth, shining, spaces equal in width to one-third diameter of a puncture; vestiture of fine, short, moderately abundant hair. Elytra 1.2 times as long as wide, 2.1 times as long as pronotum; striae deeply, narrowly impressed, punctures elongate, partly confluent; interstriae three times as wide as striae, moderately convex, surface minutely, densely, transversely crenulate, crenulations subacute, each crenulation less than one-fifth as wide as an interstriae; posterior slope of each crenulation steep, marked by a setiferous puncture; vestiture of fine, short, confused, moderately abundant hair. Declivity broadly, evenly, rather steeply convex; interstriae narrower than on disc, crenulations reduced in size and number, obscure; setae slightly stouter.

Distribution: Bolivia to French Guyana.

Bolivia: Beni; Cosincho Regn, VIII-1925, G.L. Harrington.

French Guyane: Maroni, Le Moul.

Notes: The female holotype of *Phrixosoma magna* Blackman was examined and compared by me directly to the smaller Maroni female.

Phrixosoma minor Wood

Phrixosoma minor Wood, 1956:248. Holotype ♂; La Ceiba, Honduras; USNM, Washington (References in Wood & Bright c1992:189)

Diagnosis: Female head with abruptly marked separation in sculpture between upper frons and vertex and

with lateral areas on this line subconvexly impressed; setae on discal interstriae stout, organized into three ranks.

Male: Similar to female except transition between upper frons and vertex normal, not marked by an impression.

Female: Length 1.6–2.0 mm, 2.0 times as long as wide; color black. Frons similar to *magna* Blackman, but surface more granular; line between upper frons and vertex more sharply marked, more strongly impressed in lateral areas, subconvex above eye; hairlike setae slightly longer. Pronotum 0.77 times as long as wide; outline as in the Maroni specimen of *magna*; surface rather coarsely beaded on posterior half, areas dull between smooth, shining, convex ‘beads,’ anterior third finely granulate; vestiture of fine, short, semirecumbent hair. Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; striae narrowly, rather deeply impressed, punctures small, obscure, spaced within a row by twice diameter of a puncture; interstriae at least twice as wide as striae, densely, acutely crenulate in three ranks, a seta arising from posterior base of each narrowly tuberculate crenulation; interstitial setae rather stout, close, each about equal in length to two-thirds width of an interstriae, in three ranks, those in middle rank slightly longer, especially on declivity. Declivity broadly convex, rather steep; sculpture about as on disc.

Distribution: Mexico (Oaxaca) to Venezuela.

Venezuela: 40 km SE Socopo, Barinas, 25-I-1970, No. 264, *Symphonia*, SLW; El Vigia, Merida, 19-XII-1969, No. 181, *Symphonia*, SLW.

Hosts: *Rheedia edulis*, *Symphonia globulifera*.

Biology: The bole and branches down to 3 cm in diameter were attacked. Egg galleries were biramous and transverse, although diagonal, triramous, and partly longitudinal egg galleries were not uncommon. Larval mines were short and wandered indiscriminantly.

Notes: The entire type series of *Phrixosoma minor* Wood and 216 other specimens were examined from Central America and 76 additional specimens from Venezuela.

Phrixosoma peruwiana Eggers

Phrixosoma peruwiana Eggers, 1951:148. Holotype ♂?; Peru, NHMW, Wien (References in Wood & Bright c1992:190)

Diagnosis: Distinguished by the distinctly punctured pronotum disc; and by the fine, hairlike setae on basal half of elytral disc, slightly coarser on posterior half and declivity.

Male: Length 1.9 mm, 2.0 times as long as wide; color almost black. Frons broadly convex, finely granular and with numerous close, small granules; a fine median carina on lower one-third; vestiture of fine, short, moderately abundant hair. Pronotum 0.75 times as long as wide; surface smooth, shining, median line smooth, shining, punctures near median line small, close, separate, becoming confluent in lateral areas toward base; vestiture of fine, short, moderately abundant hair. Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; rather narrowly rounded behind; striae abruptly, narrowly, moderately impressed, shining, punctures minute, distinct; interstriae about three times as wide as striae, surface partly, obscurely reticulate, subshining, armed by numerous, rather coarse, close, partly confused tubercles. Declivity convex, moderately steep; interstriae reticulate, tubercles mostly uniseriate, interstriae 8 ending before its normal apex, 3 and 7 somewhat join at their apices. Vestiture of fine hair on basal one-third of disc, gradually becoming coarser near and on declivity, central row on a discal interstriae not longer, often coarser than adjacent setae.

Distribution: Peru: "Kirsch."

Notes: The above treatment was based on the male holotype.

Phrixosoma obesa Blackman

Phrixosoma obesa Blackman, 1943:393. Holotype ♀; Gatun, Canal Zone, Panama; USNM, Washington (References in Wood & Bright c1992:190)

Diagnosis: Upper frons and vertex not clearly marked along a definite line; interstitial setae on disc finely hairlike, confused, middle row almost twice as long as others.

Male: Similar to female except for abdominal terga 7 and 8.

Female: Length 1.8–2.5 mm, 1.9 times as long as wide; color black. Frons as in *minor* Wood. Pronotum 0.80 times as long as wide; outline as in *minor*; surface densely, rather finely punctured, many confluent, interiors reticulate, interspaces smooth, shining, mostly equal in width to half diameter of puncture. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; surface similar to *magna* Blackman, except erect middle row of interstitial setae with each seta almost twice as long as others especially on declivity. Declivity broadly convex, rather steep; crenulations reduced in size and number.

Distribution: Costa Rica to Colombia.

Colombia: 8 km S Colonia (near Buenaventura), Valle del Cauca, 9-VII-1970, No. 639, *Rhedia madruno*, SLW.

Hosts: *Rhedia edulis*, *R. madruno*, *Symphonia globulifera*.

Biology: The bole of felled trees 25–35 cm in diameter were attacked. Parental galleries in the phloem were

biramous and transverse. Larval mines destroyed entirely the phloem tissues but did not engrave the wood.

Notes: The above treatment was based on 36 Central American specimens, 1 of which I compared directly to the holotype, and on 1 specimen from Colombia.

Phrixosoma frustrata Wood

Phrixosoma frustrata Wood, 1971:3. Holotype ♀; 8 km S Colonia (near Buenaventura), Valle de Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:189)

Diagnosis: This is the only known member of this genus in which the anterior margin of the female prothoracic pleuron at eye level bears a large, quadrate process that projects forward over the piece that separates the upper and lower halves of the eye.

Male: Similar to female except process absent on anterolateral margin of prothorax.

Female: Length 2.5–3.2 mm, 1.6 times as long as wide; color almost black. Frons essentially as in *minor* Wood. Pronotum 0.70 times as long as wide, posterolateral angles one-third pronotum length from basal angle at scutellum; granulation on disc similar to *virtuosa* Wood except with granules smaller, closer; vestiture of fine, short, moderately abundant hair; anterior margin bearing a large semitransparent, quadrate extension on lateral area that fits over area between upper and lower halves of eye. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; striae narrowly impressed, punctures small, separated within row by twice diameter of a puncture; interstriae about as in *magna* Blackman, crenulations small, close, confused, setae short, stout, of uniform length. Declivity rather steep, broadly convex; sculpture similar to disc.

Distribution: Colombia: 8 km S Colonia (near Buenaventura), Valle del Cauca, 9-VII-1970, 30 m, No. 639, *Rhedia madruno*, SLW.

Biology: The biramous parental galleries were longitudinal.

Notes: The above treatment was based on the type series of 93 specimens.

Phrixosoma viriosa Wood

Plate VIII

Phrixosoma viriosa Wood, 1971:2. Holotype ♀; 40 km SE Socopo, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:190)

Diagnosis: Setae on discal interstriae confused, of subequal length; anterior margin of female pronotum in lateral area without a large, subquadrate extension.

Male: Similar to female except for abdominal terga 7 and 8.

Female: Length 2.4–2.7 mm, 1.8 times as long as wide; color almost black. Frons and pronotum about as in *frustrata* Wood except disc a bit less rugose; anterolateral margin without a large extension. Elytra 1.1 times as long as wide, 1.7 times as long as pronotum; interstriae with

general surface more strongly rugose-reticulate, confused crenulations distinctly larger than in *frustrata*, setae distinctly shorter, confused, of more uniform length. Declivity similar to *frustrata* except tubercles mostly obsolete, setae shorter.

Distribution: Venezuela: 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 254, *Rheedia madruno*, SLW.

Biology: Parental galleries were biramous and longitudinal.

Notes: The above treatment was based on the type series of 98 specimens.

Phrixosoma brasiliensis Schedl

Phrixosoma brasiliensis Schedl, 1959:546. Holotype ♂?; Rio Caraguata, Mato Grosso [Brazil]; NHMW, Wien (References in Wood & Bright c1992:189)

Diagnosis: Distinguished by the small size; by the distinctive pronotum; and by details of the elytral declivity.

Male (?): Length 1.7 mm, 2.1 times as long as wide; color very dark brown (mature?).

Frons largely covered by glue (not visible), apparently somewhat flattened on lower one-third, median carina not evident. Pronotum 0.80 times as long as wide; median area on anterior one-third with numerous small tubercles; posterior areas smooth, shining, with fine, confluent punctures (almost no isolated punctures), interspaces not convex or elevated, with no reticulation or granulation on posterior half; vestiture of rather fine, long hair of moderate abundance. Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; striae shining, abruptly, narrowly, moderately impressed, punctures small, distinct, interstriae 3 joining 9, 4 joining 5, 7, and 9. Declivity convex, rather steep; surface apparently, obscurely granulate, each interstriae with a central, uniseriate row of tubercles. Vestiture of rather coarse, moderately abundant, confused, hairlike setae of about uniform length.

Distribution: Brazil: Rio Caraguata, 21°48'.B, 52°27'.L, 400 m, F. Plaumann.

Notes: The above treatment was based on the holotype that is thought to be a male.

Phrixosoma barinensis Wood, n. sp.

Phrixosoma barinensis Wood: Holotype ♀; 40 km SE Socopo, Barinas, Venezuela; USNM, Washington, designated below

Diagnosis: Distinguished from *viriosa* Wood by having declivital interstriae 1–3 each with a central row of fine tubercles, by the stouter interstitial setae; and by the smaller size.

Female: Length 2.1 mm, about 1.8 times as long as wide; color almost black. Frons and pronotum about as in *viriosa* except posteromedian area of pronotum projecting less strongly into scutellar notch. Elytra similar to *viriosa* except interstitial setae slightly stouter, declivital interstriae 1–3 each armed by a central, uniseriate row of fine tubercles; tubercles and setae on posterior half of interstriae 3–5 on posterior half of disc and on declivity mostly three-ranked.

Distribution: Venezuela (Barinas).

Type material: The female holotype was taken 40 km SE Socopo, Barinas, Venezuela, 25-I-1970, 150 m, No. 254, *Rheedia madruno*, S.L. Wood. The holotype is in the U.S. National Museum, Washington.

Biology: The unique holotype was walking actively on the surface of the same tree that was under attack by the type series of *viriosa* Wood and *rubra* Wood. Whether it was attracted by volatile substances from the tree or from pheromones of the other species could not be determined.

Phrixosoma rubra Wood, n. sp.

Phrixosoma rubra Wood: Holotype ♀; 40 km SE Socopo, Barinas, Venezuela; USNM, Washington, designated below

Diagnosis: Distinguished from *crebra* Wood by the smaller size; by the closer, more abundant, more confluence of punctures on the pronotum disc; by the numerous, minute, subtuberculate granules on the anterior third of the pronotum; by the abrupt transition on upper frons and vertex from granular to reticulate areas; and by the reddish brown color.

Male: Similar to female except abdominal terga 7 and 8.

Female: Length 1.5–1.7 mm, 1.8 times as long as wide; color dark reddish brown. Frons convex, finely reticulate-granulate from epistoma to vertex, transition to reticulate at vertex abrupt, on a definite line; surface also with numerous, shining, fine granules; a weak median carina from epistoma almost to upper level of eyes; vestiture of fine, short, inconspicuous hair. Pronotum 0.75 times as long as wide; posterior half finely, very closely punctured, puncture interiors reticulate, most punctures confluent; anterior third of pronotum with numerous, minute tuberculate granules; basal margin acutely costate except in scutellar area. Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; striae narrowly, deeply impressed, punctures small, distinct; interstriae about twice as wide as striae, crenulations three-ranked on each interstriae from base to middle of disc, middle row largest; interstitial setae three-ranked, stout, middle row on each interstriae distinctly longer, suberect. Declivity broadly convex, rather steep, only middle row of tubercles present.

Distribution: Venezuela (Barinas).

Type material: The female holotype, male allotype, and 15 paratypes were taken 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 254, *Rheedia madruno*, S.L. Wood. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Biology: The type series was attacking the same tree that contained the type series of *viriosa* Wood. They were just entering the bark and basic features of the tunnels were not yet apparent.

Phrixosoma crebra Wood

Phrixosoma crebra Wood, 1971:2. Holotype ♀; 8 km S Colonia (near

Buenaventura), Valle del Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:189)

Diagnosis: Distinguished from *rubra* Wood by the smooth, shining posterior half of the pronotum, with clear, distinct punctures, mostly not confluent, anterior third without granules; color darker.

Male: Similar to female except abdominal terga 7 and 8.

Female: Length 1.5–1.9 mm, 1.9 times as long as wide; color almost black. Frons similar to *rubra*. Pronotum 0.72 times as long as wide; outline as in *rubra*; surface smooth, shining, punctures shallow, distinct, mostly not confluent, their interiors not clearly reticulate; anterior third with punctures smaller, more widely spaced, not clearly armed by granules; vestiture fine, short, hairlike. Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; as in *rubra* except interstitial crenulations three-ranked on basal two-thirds of disc, middle row of setae erect, longer.

Distribution: Colombia: 8 km S Colonia (near Buenaventura), Valle del Cauca, 9-VII-1970, 30 m, No. 640, *Rheedia madruno*, SLW.

Biology: The biramous parental galleries were mostly longitudinal.

Notes: The above treatment was based on the type

series of 51 specimens.

Species Not Seen

Phrixosoma striata (Eggers)

Phrixosoma striata Eggers, 1929:41 (*Sphaerosinus*). Holotype, sex?; Amer. bor.; ZMA, Amsterdam (References in Wood & Bright c1992:190)

Notes: This species (3.0 mm) was named from one specimen, labeled “Amer. bor.,” and deposited in the Amsterdam Museum. In September 1965, while I was visiting Schedl at his home in Lienz, Osttirol, Austria, he showed this specimen (on loan to him) to me and requested an opinion. It was immediately recognized as a member of the *Phrixosoma*, possibly a large *obesa* Blackman (1.8–2.5 mm) or a small *magna* Blackman (3.2–3.6 mm). In a prolonged search at the Amsterdam Museum this type could not be found. An unsuccessful search of the Schedl material at Vienna was also made. In all probability, this specimen is the senior synonym of a subsequently named species that is listed in the above key. Striking characters that would set it apart from other species were not seen.

TRIBE BOTHROSTERNINI

Description: Frons sexually dimorphic, male more distinctly impressed, female usually more elaborately ornamented by setae; eye entire to sinuate; funicle 6-segmented, club symmetrical, moderately flattened, sutures indicated; procoxae moderately separated; protibiae armed on outer apical angle by a bifid process exceeding inner apical angle; pronotum unarmed (about 10 exceptions in *Cnesinus*); row of crenulations on basal margins of elytra usually poorly developed, represented in some species by a continuous costa.

Distribution: This tribe is restricted to tropical America except for two *Cnesinus* that occur in the southeastern USA.

Biology: All species are monogynous, except inbreeding or parthenogenesis apparently occurs in certain *Both-*

rostermus. All are myelophagous, except that *Bothrostermus* and *Eupagiocerus ater* Eggers are xylomycetophagous. A primitive behavioral feature occurs in *Cnesinus annectens* Wood where a typical hylesinine transverse, biramous parental gallery is formed in the cambium tissues of the host, complete with egg niches. The young larvae then feed on phloem tissues for about 2 instars before following the parent-bored passage to the pith region where they complete larval development and pupation. In all other known species a longitudinal, biramous pith tunnel is formed by the parents; eggs are then deposited in clusters in the loose frass of this cavity. The larvae then feed in congress while extending the parental pith tunnel. Pupation occurs in the larval frass in this chamber.

Key to the Genera of Bothrosternini
(Adapted from Wood 1986:46)

- 1. Lateral margins of pronotum rounded 2
- Lateral margins of pronotum marked by sharply elevated costate to subcostate line (when doubtful discal striae minutely granular to base, with punctures obscure to base) 3
- 2(1). Sutures of antennal club transverse, straight; rostrum distinctly wider than distance between eyes; pronotum either longitudinally strigose or punctured; mostly pith borers of twigs and other small stems; 1.3–3.5 mm *Cnesinus*
- Sutures of antennal club strongly procurved; rostrum width at tip equal to distance between eyes; frons excavated in both sexes, with a median tubercle just above epistoma; body oval; seed borers; 1.9–3.2 mm *Pagiocerus*
- 3(1). Sutures of antennal club strongly procurved; pith borers in twigs and woody vines (mycetophagous in the only known South American species); 2.1–3.8 mm *Eupagiocerus*
- Sutures of antennal club transverse, straight 4
- 4(3). Proepisternal area partly excavated, with cavity densely filled by yellow pubescence, particularly in female; prothoracic intercoxal piece with a transverse, subcarinate crest; elytral interstriae usually not strongly carinate; ambrosia beetles in axial pith tunnels of woody vines; 1.9–3.3 mm . . .
..... *Bothrostermus*
- Proepisternal area normal, not conspicuously pubescent; prothoracic intercoxal crest absent; elytral interstriae often partly to entirely, narrowly carinate; pith borers in branches and twigs; 2.2–3.6 mm *Sternobothrus*

GENUS *CNESINUS* LeCONTE

Cnesinus LeConte, 1868:71. Type-species: *Cnesinus strigicollis* LeConte, monobasic

Diagnosis: Lateral margins of pronotum rounded; sutures of antennal club transversely straight; punctures

of pronotum varying from almost normal to longitudinally confluent and/or strigose.

Description: Length 1.3–3.5 mm, 2.4–3.2 times as long as wide; color reddish brown to almost black. Frons sexually dimorphic, convex above, variously impressed below, male sculpture simple, female often elaborately

ornamented by setae and carinae. Antennal club rather small, modestly flattened, 3 straight sutures usually present. Pronotum usually unarmed (several exceptions); punctures simple to confluent and strigose. Elytral sculpture rather simple; vestiture varying from hairlike to broad scales, with or without ground cover.

Distribution: Tropical America, with 2 species in southeastern USA. Wood & Bright (c1992:205–212) report 101 species, 54 of which were said to occur in South America.

Biology: All species are thought to be monogynous, although males are very rare or unknown in a few species. The female apparently initiates the new parental

gallery. All species, except *C. annectens* (see Tribe Bothrostermini above), are pith borers in small stems, mostly less than 1 cm in diameter, although some breed in stems up to 5 cm in diameter. None of the species known to me have the xylomycetophagous habit. The parental pith tunnel extends in both directions from the radial entrance tunnel. Eggs are deposited in clusters mixed with boring dust. Larvae feed in congress and extend the parental pith tunnel and emerge following pupation through the parental entrance hole. They attack severed, broken or unthrifty twigs and are of little or no economic importance under most circumstances.

Key to the Species of *Cnesinus*

- 1. Frons convex in both sexes above level of antennal insertion (a narrow, weak impression on median fourth in 2 species), never with an epistomal elevation or conspicuous brush of erect setae or transverse carina; interstitial punctures on disc uniseriate (rarely irregular on 2 or 3), usually minute, discal interstitial setae absent (two exceptions); punctures on pronotum distinct, rarely elongate (about twice as long as wide), almost never confluent; smaller species 2
- Frons variously impressed on lower half in both sexes, usually ornamented by a transverse epistomal elevation, a transverse pair of tubercles (female only), a brush of erect setae (only 1 row in most males), or a transverse carina (female only) near middle; punctures on pronotum either distinct or variously confluent; interstitial punctures on disc usually confused (at least on 3); both small and larger species 15
- 2(1). Basal margins of elytra armed by a continuous, acutely elevated costa from scutellum to interstriae 7; stout erect interstitial setae continue forward from declivity to middle of disc on 2 and 3 and almost to base on 1 (not in *beaveri* or 2 and in 3 *teres*) 3
- Basal margins of elytra weakly elevated, more rounded, usually subgranular or with punctures suggesting weak formation of crenulations; vestiture usually absent on elytral disc 7
- 3(2). Pronotum closely etched longitudinally by finely substrigose, elongate punctures (almost no confluence); interstitial setae absent on anterior half of disc; frons more broadly convex, setae finer, less conspicuous; Brazil; 1.3–1.5 mm *beaveri* Wood
- Pronotum surface smooth, shining, punctures subcircular to about three times as long as wide; frons narrower, male with lateral areas ornamented by setae; interstitial setae extending to base of disc on interstriae 1 4
- 4(3). Eye very coarsely faceted, separated above by width of an eye or less; punctures on declivital striae 1 and 2 only moderately impressed, interstriae without granules; female frons smooth and polished below eyes; Venezuela; *Nectandra*; 1.4–1.5 mm *teretis* Wood
- Eyes more finely faceted, separated above by twice width of an eye; declivital striae 1 and 2 strongly impressed, interstriae 2 usually with a few small granules 5
- 5(4). Body less slender, 2.6 times as long as wide; punctures on pronotum slightly smaller, closer, mostly two to four times as long as wide; interstriae 1 (without any tubercles on disc or declivity), 2–4 with tubercles confined to declivity; Brazil (Santa Catarina); 1.5–1.7 mm *plaumanni* Schedl
- Body more slender, 2.7 times as long as wide; punctures on pronotum slightly larger, not as close, mostly 4 times as long as wide 6
- 6(5). Declivity convex, interstriae 1 with a row of fine tubercles from base of disc to apex, 2 to 4 with declivital tubercles extending cephalad to posterior one-fourth of disc; Colombia; *Xelopia*; 1.5–1.6 mm *pulchellus* Wood

BOTHROSTERNINI

- Declivity rather strongly sulcate between left and right interstriae 4, 4 much higher than suture; all interstriae devoid of tubercles on disc and declivity; vestiture on disc of minute, very fine, short hair, on declivity of numerous short scales; Colombia to Venezuela; 1.2–1.7 mm *teres* (Chapuis)
- 7(2). Lower half of frons broader (1 species) or middle one-third (of area from epistoma to upper level of eyes) with a small to moderate shallow concavity on median one-fourth, lower margin of impressed area modestly elevated and armed on female by a transverse pair of tubercles (indefinite in 2 of these species); elytral declivity with interstriae 2 rather strongly impressed, distinctly wider than 1 or 3, its surface smooth, brightly polished, a few very minute punctures indicated 8
- Frons without an impression above level of antennal insertion; declivital interstriae 2 weakly or not impressed or wider than 1 or 3 10
- 8a(7). Frons broadly, moderately concave on lower half or more of area below upper level of eyes (female not seen) 8b
- Frontal impression restricted to much less than lower half; discal interstriae smooth, punctures uniseriate 9
- 8b(8a). Frons moderately concave on lower half of area below upper level of eyes, area at upper level of eyes rounded (unmodified); discal interstriae 2–5 weakly reticulate, punctures very small, confused (female not seen); Brazil (Santa Catarina); 2.5 mm *amplipennis* Schedl
- Female (?) frons more broadly, shallowly impressed three-fourths distance toward upper level of eyes, a low, subacute transverse carina on median half at upper level of eyes; epistomal callus feebly developed, with erect laterally compressed setae with a slightly reddish tint; frons more shallowly impressed on lower half, then evenly convex to above upper level of eyes (no carina); apex of elytral suture shallowly imarginate, apex of elytra at lateral end of emargination slightly flared upward and bluntly pointed; Brazil (Santa Catarina); 1.8–1.9 mm *bicinctus* Schedl
- 9(8). Female frons on median line at upper margin of concavity more evenly rounded without a definite tubercle, lower margin of concavity with a transverse pair of rather conspicuous denticles; pronotum less brightly shining, punctures larger, closer, especially on basal one-fourth, punctures longitudinally elongate; striae punctures distinctly larger; declivity with striae punctures minute, lateral convexities on interstriae 3 more broadly rounded; Venezuela; Bejuco blanco; 2.5–2.6 mm *alienus* Wood
- Female frons on median line at upper margin of concavity with a poorly formed, definite tubercle, lower margin of concavity with indefinite granules, without a definite, transverse pair of tubercles, vestiture less abundant, shorter; pronotum brightly shining, punctures minute, about as wide as long, smaller, more uniformly distributed; striae not impressed, punctures smaller; declivity with striae punctures conspicuously larger, lateral convexities on interstriae 3 more narrowly convex, subsulcate; Brazil; 2.7 mm *carbonarius* Schedl
- 10(7). Surfaces of head, pronotum, and elytra conspicuously reticulate throughout; striae impressed, continuously granular; striae punctures obscure; basal third of pronotum coarsely, closely shallowly punctured; Venezuela; *Vismia cayennensis*; 1.9–2.0 mm *reticulus* Wood
- Surfaces of pronotum and elytra smooth, shining; striae not granular or dull, punctures clearly, individually impressed 11
- 11(10). Frons transversely impressed on lower fourth, almost flat, lower three-fourths (including impressed area) ornamented by a brush of moderately long hair; anterior third of pronotum somewhat shagreened or not 12
- Frons with convex area extending almost to level of antennal insertion (1 exception), impressed area less extensive, frontal vestiture much less abundant, shorter, finer, less conspicuous; pronotum shining throughout, without any shagreening 13

- 12(11). Anterior one-third (or more) of pronotum shagreened, punctures mostly smaller, more elongate, each 2–4 times as long as wide, rarely confluent; interstitial punctures very small, equal to less than one-third diameter of a strial puncture; female frons with a tuft of short hair on central half; body color dark brown, pronotum much darker; Mexico (Oaxaca) to Brazil (Santa Catarina); *Coffea arabica*, *Persea americana*, *Serjania*; 1.9–2.3 mm ***gracilis* Blandford**
- Pronotum without any shagreening, surface shining, punctures mostly slightly larger, mostly less than twice as long as wide, several punctures confluent on basal half; interstitial punctures slightly larger, equal to at least half diameter of a strial puncture; body color medium brown; Venezuela to Guiana; 1.7 mm ***minusculus* Schedl**
- 13(11). Frons weakly, transversely impressed on lower third, convex above; pronotum closely strigose, all punctures longitudinally strigose, most confluent; sutural apex of elytra moderately produced, lower interstriae 1 and costal margin near suture on declivity moderately elevated; Brazil (Santa Catarina); 1.5 mm ***acuminatus* Schedl**
- Lower frons convex to level of antennal insertions; punctures on pronotum individually impressed, with little or no strigation or confluence 14
- 14(13). Frons more strongly convex, with several moderately coarse granules at and below (orad) summit, less conspicuous in male; setae on lateral areas of declivity shorter, coarser, subequal in length to those on interstriae 1 and 2, setae on 2 normal, erect; Bolivia, Peru, Venezuela; 2.3–2.4 mm ***nitidus* Eggers**
- Frons moderately convex, its summit usually not armed by granules in either sex; lateral declivital setae conspicuously longer and more slender; shorter on interstriae 1 and 2, setae on 1 conspicuously diverge away from suture; Argentina to S Brazil; *Acacia nigra*; 2.0–2.1 mm ***dividuus* Schedl**
- 15(1). Female frons without a transverse carina near middle, epistoma above callus ornamented by a multiple tiered brush (usually confused) of short, reddish brown setae of uniform length, a median elevation or transverse pair or large, pointed tubercles often immediately below these setae, male similar but less elaborately ornamented (elevation and tubercles usually absent); pronotal vestiture sparse to absent, surface usually punctured or less coarsely strigose; discal interstriae often (not always) uniseriately punctured, declivital setae usually uniseriate and without supplemental ground setae (most doubtful species with anterolateral area of pronotum armed by a row of about 5–9 crenulations) 16
- Female frons armed near middle by a transverse carina, male and female epistoma ornamented by a single row of pale, reddish brown setae well below carina; pronotum vestiture abundant, surface rather coarsely strigose; discal interstriae with punctures confused, abundant vestiture, and usually with a row of longer, erect bristles on each interstriae (never with a row of crenulations on anterolateral area of pronotum) 43
- 16(15). Anterolateral angles of pronotum without a row of rather coarse crenulations; pronotum usually without conspicuous vestiture; most or all of setae on discal interstriae obsolete; pronotal strigation usually coarser 17
- Each anterolateral area of pronotum armed by a sublongitudinal row of about 5–9 coarse crenulations; pronotum usually with conspicuous, abundant vestiture, longitudinal striation usually much more coarse; discal interstriae conspicuously pubescent to base 35
- 17(16). Female epistomal elevation strongly, acutely elevated at median line, its summit armed by 1 or a transverse pair of tubercles or denticles, upper half of frons less shining, less subglobular, its lateral areas with more, longer pubescence to above eyes 18
- Female epistomal elevation variously sculptured, never armed by a conspicuous median tubercle or transverse pair of tubercles; upper half of frons to above eyes smooth, shining, impunctate, a partial subglobular appearance, vestiture often entirely obsolete or reduced in size and number of setae 20

BOTHROSTERNINI

- 18(17). Larger species; female median epistomal elevation much larger; armed by a transverse, closely set pair of tubercles; interstrial punctures on disc numerous, confused; eyes more widely separated above, space between eyes equal to twice width of an eye; pronotum longitudinally strigose, punctures obscure, almost totally confluent; interstrial setae abundant, confused, moderately long, without recognizable central rows; Colombia to Peru; 3.1 mm *reticulatus* (Chapuis)
- Smaller species; pronotal punctures distinct, longitudinally elongate, few confluent; interstrial punctures on disc mostly uniseriate, disc mostly glabrous, setae on declivity in uniseriate rows; eyes separated above by half to full width of an eye 19
- 19(18). Female epistomal elevation armed by a single median tubercle; eyes large, coarsely faceted, separated above by a distance equal to one-half width of an eye; punctures on pronotum distinct, separate, each longitudinally etched (about 4–6 times as long as wide, almost never confluent); Colombia; 1.7–1.9 mm *excellens* Wood
- Female epistomal elevation armed by a transverse pair of rather widely spaced, moderately large, pointed tubercles; eyes separated above by distance equal to width of an eye; punctures on pronotum distinctly larger, closer, many confluent; Mexico (Oaxaca) to Colombia (?); *Coffea arabica*, *Persea americana*, *Serjania*; 2.4–2.8 mm *elegans* Blandford
- 20(17). Pronotal punctures longitudinally confluent; usually interstrial punctures on disc numerous, confused (2 species) or rows of erect interstrial setae extending to base (and on pronotum) and punctures uniseriate (1 species) 21
- Pronotal punctures distinct, mostly isolated, few confluent; interstrial setae uniseriate (rarely confused on 3), disc and pronotum almost glabrous 27
- 21(20). Larger, stouter species; discal interstriae with numerous, confused punctures; elytra and pronotum subglabrous; female epistomal elevation small, brush of reddish brown setae large and occupying almost lower half of area below upper level of eyes; Colombia; “matapalos”; 2.8–3.0 mm *colombianus* Wood
- Smaller, more slender species; discal interstriae with punctures mostly uniseriate, with setae extending to base and also numerous on pronotum; female reddish brown frontal brush much smaller, about half as large 22
- 22(21). Elytral declivity with interstriae 1–3 about equal in convexity and sculpture, 2 with setae to apex 23
- Elytral declivity with interstriae 1 flat or weakly elevated and without tubercles, 3 more strongly, more narrowly convex almost to apex, striae 1 and 2 obsolete or at least reduced on lower half (punctures present in *gibbus*), broadly flattened, smooth and shining, continuous with interstriae 2, a few punctures (origin interstriae 2?) sometimes present, uniseriate setae on (sometimes 1) 3, glabrous on lower half or all of 2 26
- 23(22). Elytral striae and interstriae rugose-reticulate to densely micropunctate, rather dull; declivity with both short strial and longer interstrial rows of setae; Brazil (Santa Catarina); 1.7 mm *pusillus* Schedl
- Elytral surfaces smooth, shining; mostly larger species; strial setae obsolete 24a
- 24a(23). Punctures of declivital striae 1 and 2 obscure but visible, interstriae 2 very narrow but present at least on upper half 24b
- Punctures on declivital striae 1 and 2 obsolete, interstriae 2 obsolete, setae absent 25
- 24b(24a). Declivital interstriae 2 narrow above, obsolete below (with setae present on upper half); apex of elytra normal; Venezuela (Cumana); 2.4 mm *gibbus* Chapuis

- Declivital interstriae narrow, continued to apex (with tubercles and setae present, apex of elytra at suture prolonged into a conspicuous, tapered spine longer than its basal width; Brazil (Mato Grosso, Sao Paulo); 1.7–1.9 mm *bispinatus* Schedl
- 25(24a). Pronotum distinctly wider than long; discal interstriae 2 and 4 with setae uniseriate; all setae on pronotum and elytra coarse; epistomal elevation (shining area larger, wider); Colombia; “matapalo & guamo seco”; 1.9–2.2 mm *foratus* Wood
- Pronotum distinctly longer than wide; discal interstriae 2 and 4 with setae confused; all setae on elytra and pronotum much more slender; shining area of epistomal elevation smaller; Colombia; *Quercus humboldtii*; 2.7–2.8 mm *deperditus* Wood
- 26(22). Declivital interstriae 1 and 2 flat, impunctate, and glabrous from base to apex; discal striae almost obsolete, punctures minute, interstitial punctures minute, confused; female epistomal callus weak, poorly formed, frontal impression extending almost to upper level of eyes; Brazil (Santa Catarina); 3.0–3.2 mm *schoenherri* Schedl
- Declivital interstriae 1 weakly elevated and uniseriately punctured to near apex; discal striae distinctly, rather abruptly impressed, punctures largely confluent, obscure, interstriae moderately punctured; female epistomal callus distinct, frontal impression ending well below upper level of eyes; Brazil (Sao Paulo to Santa Catarina); 2.0–2.3 mm *sulcatus* Eggers
- 27(20). Median half of posterior half of pronotum with punctures replaced by rounded granules, reticulate between granules; striae rugose-reticulate and without punctures from base to base of declivity; interstriae with small punctures close, confused; vestiture of fine hair; Brazil; 3.7 mm *grandis* Schedl
- Pronotal punctures on mesal half of basal half present, variously confluent, tubercles not evident 28
- 28(27). Declivital interstriae 1 and 2 with coarse, uniseriate setae to apex; basal half of pronotum with large, shallow, very close punctures, equally close but much smaller on anterior half; Suriname; 1.8 mm *schulzi* Wood
- Declivital interstriae 1 and 2 sometimes without rows of setae; punctures on basal half of pronotum subequal in size with those on anterior half 29
- 29(28). Female epistomal elevation smooth, brightly shining, its lower (orad) margin not sharply defined, a short row of setiferous punctures on lateral thirds separate shining area from margin, median third not separated from obscure median epistomal lobe, upper margin of elevation sharply, obtusely defined, reddish brown band of setae about two ranks thick, at least as wide as elevated area; setae on elytra very fine, rather long; Bolivia to Peru, elevation 3600–4100 m; 2.5–2.7 mm *bicolor* Eggers
- Lower (orad) margin of female epistomal elevation sharply defined, separate from epistomal margin, its upper margin poorly defined; elytral setae slender 30
- 30(29). Female epistomal elevation with much more than dorsal half covered by reddish brown brush of uniformly short setae, small lower area smooth, shining; most (more than half) of pronotum dull 31
- Female epistomal elevation much narrower, with more than lower half smooth, shining, its upper margin more narrowly (but obtusely) angled; pronotum mostly shining, less than anterior third dull 33
- 31(30). Female frontal elevation 0.76 times as wide as lower frons, smooth shining area extending from lower margin at lateral ends arcuate to slightly less than lower half at median line (not forming an angle); pronotum dull to middle on disc and much nearer base laterally, punctures moderately small; Venezuela; *Rubus*; 2.5–2.9 mm *fulgens* Wood

BOTHROSTERNINI

- Female frontal elevation 0.70 times as wide as lower frons, less than lower third on median one-fourth to one-half smooth, shining; pronotum dull almost to base 32
- 32(31). Punctures on pronotum oval, less numerous, weakly (if at all) strigose; female epistomal elevation narrower, its lower margin more strongly procurved; Brazil; 2.1 mm *bituberculatus* Schedl
- Punctures on pronotum distinctly strigose, much more numerous; epistomal elevation wider, its lower margin almost straight; Colombia to Venezuela; *Rubus*; 2.4–2.7 mm *bisulcatus* Schedl
- 33(30). Eyes larger, very coarsely faceted, separated above by slightly more (1.1 times) than width of an eye; female epistomal elevation 0.55 times as wide as width of lower frons; Colombia; *Coffea*; 2.2–2.5 mm *meris* Wood
- Eyes normal, much more finely faceted, separated above by twice width of an eye 34
- 34(33). Female epistomal elevation 0.55 times as wide as width of lower frons, smooth area much wider than long; pronotum smooth, shining over more than basal three-fourths, punctures rather fine, slightly strigose; Colombia; *Quercus humboldtii*; 2.3–2.5 mm *fulgidus* Wood
- Female epistomal elevation 0.40 times as wide as lower frons, smooth area distinctly longer than wide; pronotum smooth, shining over more than basal half, punctures very fine, not strigose; Colombia to Venezuela; “Uvo de Monte & Graptero”; 2.2–2.5 mm *triangularis* Wood
- 35(16). Vestiture on pronotum and elytra of abundant, short ground setae and also, on interstriae, uniseriate rows of erect setae 36
- Elytral vestiture of interstitial rows of erect setae, ground cover absent 41
- 36(35). Ground cover on pronotum and elytra of abundant, pale scales, each scale rather large, each about as wide as long; erect interstitial bristles spaced within a row by twice length of a bristle, their length equal to two-thirds distance between rows; Argentina; 2.2 mm *squamifer* Wood
- Ground cover on pronotum and elytra slender, varying from almost hairlike to rather coarse 37
- 37(36). Larger species; interstitial punctures on 1 and 2 of disc clearly impressed; erect bristles on declivity more slender, pointed, each much longer than distance between rows at least in female (long setae mostly absent in male *vestitus*) 38
- Smaller species; interstitial punctures on 1 (and sometimes 2) on disc obsolete; erect bristles on declivity usually stout, usually blunt, length of each equal to or shorter than distance between rows 39
- 38(37). Female epistomal callus with a small median tubercle on its lower margin, reddish brown brush of setae less extensive, consisting of about a double-ranked, transverse band; declivital striae 1 impressed, impunctate, as wide as interstriae 2 (on right side); Argentina to Bolivia; 2.8 mm *hispidus* Eggers
- Female epistomal callus unarmed by a median tubercle, brush of reddish brown setae much more extensive and of brighter color; declivital striae 1 narrowly impressed, half as wide as interstriae 2 (on right side); Venezuela; *Bambusa vulgaris*; 3.3–3.6 mm *vestitus* Eggers
- 39(38). Female epistoma unarmed; upper frons reticulate or smooth; erect interstitial setae extending at least to posterior half of disc 40a
- Female frons armed on epistomal margin by a pointed median spine or by a blunt, apically flattened spine occupying almost median one-fifth; median two-thirds of distance between eyes smooth, shining; discal interstriae granular, punctures not clearly evident; erect interstitial setae on or near declivity with longest setae equal in length to width of an interstriae 40b

SCOLYTIDAE OF SOUTH AMERICA

- 40a(39). Upper half of frons rather strongly reticulate; discal striae less abruptly, more widely impressed; discal interstriae very slightly wider than striae; declivital striae narrowly impressed, punctures minute to obsolete; Bolivia; 2.3 mm **setosus** Eggers
- Upper half of frons smooth, shining; striae abruptly, more narrowly impressed; interstriae twice as wide as striae; declivital striae 1 and 2 less strongly impressed, punctures distinctly, rather strongly impressed; Brazil (Mato Grosso) to Paraguay; 1.6–2.0 mm **advena** Schedl
- 40(b). Female epistoma armed by a small median conical tubercle; longest setae on and near declivity blunt, apically flattened; Brazil (Maranhao); 1.75 mm **hispidulosus** Wood
- Female epistoma armed on margin by a blunt, apically flattened spine occupying almost median fifth of epistoma width; longest setae on and near declivity mostly pointed; Argentina; 2.2 mm **ampliatius** Schedl
- 41(35). Reddish brown setae on upper slope of female epistomal elevation sparse, organized into a single transverse row; female frons armed near middle on median line by a moderately large tubercle (or very short, transverse carina); posterolateral areas of pronotum with many punctures separate, with little confluence; Colombia; *Coffea arabica*; 1.9–2.4 mm **robai** Blackman
- Reddish brown setae on upper slope of female epistomal elevation more abundant, spread over much larger area; female frons without a conspicuous tubercle near center; posterolateral areas of pronotum with almost all punctures confluent, not discernible 42
- 42(37). Lateral margins of lower female frons abrupt, area nearest emargination of eye less strongly elevated; reddish brown brush of setae much smaller, yellowish, comparatively dull; Venezuela; *Rubus*, *Vismia*; 2.3–2.5 mm **lucaris** Wood
- Lateral margins of lower female frons acutely elevated, dorsolateral end at situation of eye much more strongly elevated; reddish brown brush on female epistomal elevation much more extensively distributed and much more brightly colored (reddish); Colombia; *Coffea arabica*; 2.3–2.5 mm **coffaeae** Schedl
- 43(15). Elytral striae on disc strongly impressed, interstriae carinate to bicarinate (with central area subsulcate and uniseriately punctured between elevated margins), vestiture hairlike; transverse female carina almost straight, extending from eye to eye at level of ocular emargination 44
- Discal interstriae flat or convex, never carinate (or bicarinate), punctures confused, vestiture usually abundant, somewhat scalelike; female carina crescent-shaped, its arms extending slightly dorsolaterad, usually shorter and located lower on frons 45
- 44(43). Female frons above carina smooth, shining, usually with a few minute, impressed points; ground vestiture on elytral declivity less abundant, major setae usually finer, longer; rugae on pronotum usually coarser; Mexico (Oaxaca) to Colombia and Venezuela; *Persea americana*, unidentified Lauraceae sp., etc.; 2.0–2.3 mm **costulatus** Blandford
- Female frons above carina reticulate, dull; declivital ground vestiture more abundant, major setae usually coarser, shorter; pronotal rugae usually finer; Guatemala to Venezuela; *Guasuma ulmifolia*, *Oreopanax*, *Quercus*, etc.; 2.8–3.1 mm **porcatus** Blandford
- 45(43). Elytral apices extended caudad (behind), broadly emarginate at suture; declivital interstriae 1, 3, 5, and 9 elevated; elytra ground cover of broad scales, each scale almost as wide as long, scales on pronotum similar but slightly more slender; Costa Rica to Venezuela; *Serjania* and other lianas; 1.7–2.1 mm **squamosus** Wood
- Elytra more broadly rounded behind, not emarginate at suture; vestiture much more slender (more than 4 times as long as wide); declivital interstriae not elevated 46

- 46(45). Female frons without row of short, stout, reddish brown setae between epistoma and frontal carina (setae present in male, carina absent); transverse female carina at level of antennal insertion, very strongly, acutely elevated on median one-fourth of width of lower frons; body color dark reddish brown; Costa Rica to Venezuela; *Oreopanax capitata*, *Serjania*; 1.8–1.9 mm **denotatus Wood**
- Female frons with a row of reddish brown setae on epistoma; female frontal carina placed well above level of antennal insertion 47
- 47(46). Female frons broadly flattened below from epistoma to narrowly at upper level of eyes; transverse carina in impressed area at or slightly below middle, its (transverse) width occupying median one-fifth; Honduras to Colombia (?); *Valeria scandens*; 2.1–2.4 mm **adustus Schedl**
- Female frons convex on upper half (dorsad from carina), carina at margin of impressed area; female carina occupying one-third or more of width of frons 48
- 48(47). Eyes enlarged, very coarsely faceted, separated above by less than one-half width of an eye; Honduras to Venezuela; *Serjania mexicana*; 2.4 mm **ocularis Chapuis**
- Eyes normal, separated above by twice width of an eye; Honduras to Colombia; *Acacia pennatula*, *Coffea arabica*; 2.7–3.0 mm **adusticus Wood**

Cnesinus beaveri Wood

Cnesinus beaveri Wood, 1974:2. Holotype ♀; 260 km N Xavantina, Mato Grosso, Brazil; BMNH, London (References in Wood & Bright c1992:206)

Diagnosis: Frons rather strongly convex in both sexes to epistoma; pronotum longitudinally etched, punctures elongate, not confluent; basal margins of elytra armed by an acutely elevated costa; interstitial setae absent on anterior half of disc.

Female: Length 1.3–1.5 mm, 2.7 times as long as wide; color dark brown. Frons evenly convex from level of antennal insertion to vertex; surface strongly reticulate, punctures sparse, obscure; vestiture of sparse, short hair; eyes spaced above by 2.0 times width of an eye. Pronotum 1.1 times as long as wide; surface smooth, shining, punctures fine, longitudinally striate, each striation 2–8 times as long as wide; sparse vestiture confined to anterior third. Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; crenulations on basal margins obscure; striae weakly impressed, punctures rather coarse, distinctly impressed; interstriae distinctly wider than striae, shining, almost smooth except for short, transverse lines, punctures fine, close, uniseriate. Declivity steep, convex; striae punctures slightly smaller and deeper than on disc; interstriae 1 distinctly, others weakly impressed; vestiture largely confined to declivity, of slender interstitial bristles, each bristle with its apical third appearing flattened, each two-thirds as long as distance between rows, spaced within a row by length of a bristle.

Distribution: Brazil: 260 km N Xavantina, Mato Grosso, 3-X-1-XII-1968, R.A. Beaver.

Hosts: *Guatteria* sp., *Siparuna guianensis* (Bright & Skidmore 1997:41).

Notes: The above treatment was based on the type series of *beaveri* of 6 specimens.

Cnesinus teretis Wood

Cnesinus teretis Wood, 1974:3. Holotype ♀; 7 km NW Socopo, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:212)

Diagnosis: Frons convex in both sexes above level of antennal insertion; eyes coarsely faceted, separated above by distance equal to less than width of an eye; declivital striae 1 and 2 strongly impressed, interstriae 2 armed by a few small granules.

Male: Similar to female except frons weakly, transversely impressed on lower half, more strongly convex above, surface reticulate.

Female: Length 1.3–1.5 mm, 2.7 times as long as wide; color dark brown, pronotum almost black. Frons moderately convex from epistoma to vertex, narrow, median two-thirds on lower half smooth, polished, devoid of punctures or setae; lateral areas below subreticulate, a row of setae on margin of eye above; eyes separated above by distance equal to half width of an eye. Pronotum 1.15 times as long as wide; punctures elongate. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; punctures small, shallow; interstriae twice as wide as striae, almost flat, smooth, shining, uniseriate punctures minute. Declivity steep, convex; striae impressed, interstriae 1 convex, punctures replaced by granules; vestiture confined to declivity, posterior half of discal interstriae 3, 5, and 7 consisting of coarse bristles up to twice as long as distance between rows, slightly longer than distance between bristles within a row.

Distribution: Venezuela: 7 km NW Socopo, Barinas, 13-II-1970, 200 m, No. 322, *Nectandra* twigs, SLW.

Biology: Pith borers in small twigs.

Notes: The above treatment was based on the type series of 37 specimens.

Cnesinus plaumanni Schedl

Cnesinus plaumanni Schedl, 1963:220. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:210)

Diagnosis: Distinguished from *pulchellus* Wood by the slightly more slender body form; by the smaller, shorter, closer punctures on the pronotum; and by the absence of tubercles on interstriae 1 from base to apex.

Male: Length 1.5–1.7 mm, 2.6 times as long as wide; color very dark brown. Frons with eyes separated above by about twice width of an eye, weakly convex from epistoma to vertex, surface microscopically, transversely etched; upper half with sparse, minute punctures on upper half and laterally below; vestiture of sparse, moderately long hair; epistomal callus not evident. Pronotum 1.2 times as long as wide; widest on anterior third, sides feebly constricted on posterior half; surface smooth, shining, punctures small, rather deep, close, elongate, most twice as long as wide. Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; basal margin of elytra marked by a continuous costa; striae weakly impressed, punctures rather small, distinctly impressed; interstriae almost twice as wide as striae, surface shining, with a few transverse lines, punctures minute, uniseriate, without tubercles to base of declivity. Declivity broadly convex, steep; striae 1 slightly impressed, 2 and 3 not impressed, punctures smaller than on disc; interstriae 1 with a row of fine punctures to apex, 2 and 3 with punctures replaced by a sparse row of fine tubercles. Vestiture of rows of erect interstitial setae, short and more slender on disc (some extending to base), stouter and longer on declivity (some twice as long as distance between rows).

Female: Similar to male except frons rugose-reticulate, a few minute granules present, setae longer and slightly more numerous in lateral areas.

Distribution: Brazil: Santa Catarina, Nova Teutonia, XII-1955, IV-1956, F. Plaumann.

Notes: The above treatment was based on the male holotype, female allotype, and 2 paratypes of *plaumanni* Schedl. The female allotype of *Cnesinus bituberculatus* Schedl is an incorrectly identified member of this species.

Cnesinus pulchellus Wood, n. sp.

Cnesinus pulchellus Wood: Holotype ♂; 24 km E Barbosa, Antioquia, Colombia; USNM, Washington, designated below

Diagnosis: Closely allied to *beaveri* Wood except pronotum smooth, shining, punctures subcircular; eyes finely faceted, separated above by twice width of an eye; declivital striae 1 and 2 impressed, 2 with a few granules.

Male: Length 1.5–1.6 mm, 2.5 times as long as wide; color almost black. Frons convex above level of antennal insertion, rugose-reticulate on lower two-thirds, reticulate above, a few small, subgranulate punctures below eyes in lateral areas; a few short, stout setae below eyes in lateral areas. Pronotum 1.1 times as long as wide;

sides feebly constricted on posterior half; surface dull on anterior one-third, subshining behind, mostly minutely, longitudinally etched, punctures small, elongate, each about 3–6 times as long as wide; subglabrous except at margins. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; basal margins of elytra subacutely, moderately elevated; striae weakly impressed, punctures moderately coarse, very close; interstriae weakly convex, slightly more than twice as wide as striae, shining, mostly smooth, minute punctures almost uniseriate except confused on basal half of disc on 2. Declivity convex, very steep; striae 1 moderately impressed, 2 with several granules; vestiture largely confined to erect interstitial bristles on declivity, continued on interstriae 1, 3, and 5 to one-third disc length from base; bristles rather short, widely spaced.

Distribution: Colombia.

Type material: The male holotype was taken 24 km E Barbosa, Antioquia, Colombia, 18-VII-1970, 1200 m, No. 694, *Xelopia*, S.L. Wood; 1 male paratype is from El Bosque, Caicedonia, Valle del Cauca, Colombia, 30-VI-1959, *Coffea arabica* rama seca, J. Restrepo. The holotype and paratype are in the U.S. National Museum, Washington.

Biology: Taken from pith tunnels in small branches.

Cnesinus teres Blandford

Cnesinus teres Blandford, 1896:141. Lectotype ♂; probably Colonia Tovar, Aragua, Venezuela, NHMW, Wien, designated below (References in Wood & Bright c1992:212)

Diagnosis: Distinguished from *pulchellus* Wood by the strongly impressed elytral declivity, with no tubercles on any interstriae on disc or declivity; and by the vestiture on the elytral disc of fine, minute hair, of slender abundant scales on the declivity.

Male: Length 1.2 mm, about 2.7 times as long as wide; color black. Frons convex, lower third with a weak, transverse impression, surface dull, rugose-reticulate, with several minute, shining points (apparently minute granules); vestiture of sparse, short coarse hair on lower half; eyes rather finely faceted, eyes separated above by 3.0 times width of an eye. Pronotum 1.2 times as long as wide, widest near base, almost as wide one-third pronotum length behind anterior margin, sides distinctly constricted between these points; surface smooth, shining, punctures moderately small, rather close, each about 2–4 times as long as wide, confluence rare; glabrous. Elytra about 1.7 times as long as wide, 1.7 times as long as pronotum; basal margins each a continuous costa, with no submarginal crenulations; striae narrowly, abruptly, moderately impressed, punctures on 1 and 2 mostly lost through confluence, 3–8 with normal punctures; interstriae almost three times as wide as striae, shining, surface weakly, transversely wrinkled, punctures minute, abundant, confused. Declivity broadly, rather deeply sulcate from base to apex, abrupt, steep; striae not impressed, punctures distinctly impressed, interstriae 1 and 2

impressed, rising laterally to broadly rounded crest on 4–5, no granules or tubercles on any interstriae on disc or declivity; much of surface concealed by scales. Vestiture on disc of minute, fine, very short hair (each equal in length to less than one-third width of an interstriae), and rather abundant, short scales on declivity, each scale about 3–4 times as long as wide.

Female: Similar to male except frons with median half distinctly convex from epistoma to three-fourths distance to upper level of eyes, inflated area smooth, shining, impunctate, without setae, a few short, stout setae on lateral margin.

Distribution: Colombia to Venezuela.

Colombia: “Colombie, Thozey.”

Venezuela: Colonia Tovar, Aragua (probably near the Moritz home).

Notes: The above treatment was based on the syntype in the Chapuis Collection, IRSNB, Brussels. Four syntypes are in NHMW, Wien. This Chapuis syntype is here designated as the lectotype of *Cnesinus teres* Blandford. Two specimens taken by Moritz at Colonia Tovar are in the BMNH, London.

Cnesinus amplipennis Schedl

Cnesinus amplipennis Schedl, 1963:219. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood and Bright c1992:205)

Diagnosis: Rather remotely allied to *alienus* Wood and *dividuus* Schedl, distinguished by the frons being more broadly, more strongly impressed on lower half; by the reticulate elytral interstriae, with interstitial punctures confused; and by the poorly elevated granular basal margins of the elytra.

Male: Length 2.5 mm, 2.35 times as long as wide; color reddish brown. Frons broadly, moderately impressed and shallowly concave on slightly more than lower half, upper area broadly, rather strongly convex; surface reticulate from vertex almost to epistoma; without an epistomal callus, brush of setae, or tubercles; vestiture of fine, moderately abundant, rather short hair uniformly distributed on lower half; lower half with fine, shallow, moderately abundant punctures. Pronotum 1.0 times as long as wide; widest slightly anterior to middle; most of surface finely reticulate; punctures fine, shallow, rather close, elongate, most almost 4 times as long as wide, a few confluent; glabrous. Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; basal margins abrupt, weakly elevated, obscurely subcrenulate; striae not impressed, punctures moderately small, shallowly impressed, shining, those on 1 mostly confluent, others separately impressed; interstriae about three times as wide as striae, surface finely reticulate, punctures minute, confused, rather numerous. Declivity convex, rather steep, occupying about one-third of elytral length; sculpture about as on disc except striae 1–4 feebly impressed, their punctures slightly deeper. Vestiture largely confined to declivity, mostly of uniseriate interstitial rows of bristles and sparse, almost hairlike ground setae.

Distribution: Brazil: Nova Teutonia, Santa Catarina 27°11' B, 52°23' L, VIII-1954, 300–500 m, F. Plaumann; Aracruz, Espiritu Santo, 16-I-1989, 2447.

Notes: The above treatment was based on the male holotype from Brazil and on 6 specimens from Aracruz that are probably this species.

Cnesinus bicinctus Schedl

Cnesinus bicinctus Schedl, 1954:29. Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:206)

Diagnosis: Apparently allied to *amplipennis* Schedl, distinguished by the smaller size; by the more extensively, shallowly impressed female frons, with a transverse carina at the upper level of the eyes; and by a small emargination at the apex of the elytral suture, with the apex of the elytra flared upward and bluntly pointed; the male frons is more shallowly impressed and lacks a transverse carina at the upper level of the eyes.

Male: Similar to female except frons different as in above diagnosis.

Female: Length 1.8–1.9 times as long as wide; pronotum almost black, elytra dark reddish brown. Frons moderately, rather broadly, shallowly concave from epistoma three-fourths distance toward upper level of eyes, a low, subacute transverse elevation on median half at upper level of eyes; area above epistoma bearing on median third a feebly developed epistomal callus bearing a dozen or more weakly, laterally compressed, obscurely reddish erect setae; surface above callus subshining, rather closely, finely punctured to and slightly above carina; vestiture (except on callus) of rather abundant hairlike setae of moderate length eye to eye from callus to vertex. Pronotum 1.0 times as long as wide; widest slightly anterior to middle of pronotum length; sides weakly arcuate on middle third, almost straight (diverging slightly) on basal third, broadly rounded in front; surface shining, finely, closely strigose on basal three-fourths, punctures in grooves scarcely evident on median half of strigose area, distinctly impressed on lateral thirds, anterior area obscurely strigose to somewhat finely granulose; vestiture of fine, hairlike, rather short, semirecumbent setae of moderate abundance. Elytra 1.8 times as long as wide, 1.9 times as long as pronotum, slightly wider at base of pronotum; basal margins with a row of very small, close crenulations; disc occupying basal 70 percent of elytra length; striae distinctly, narrowly impressed, punctures rather small, moderately impressed; interstriae about twice as wide as striae, smooth, brightly shining, punctures very small, confused except uniseriate on 1, slightly larger near base of declivity. Declivity steep, broadly convex, posterior outline rather narrowly emarginate at apex of suture, apex of elytra flared slightly upward, each angle bluntly pointed; striae 1 and 2 more narrowly impressed than on disc; interstriae 1–3 narrower than on disc, punctures uniseriate. Vestiture of

rather sparse, recumbent, short ground setae on disc and declivity and uniseriate rows of erect longer interstitial setae mostly on and near declivity.

Distribution: Brazil: Nova Teutonia, Santa Catarina, 27°11'B, 52°23'L, 9-X-1949, 300–500 m, F. Plaumann (holotype, allotype).

Notes: The above treatment was based on the female holotype and male allotype. Labels on these specimens have the sexes reversed.

Cnesinus alienus Wood

Cnesinus alienus Wood, 1974:3. Holotype ♂; 40 km SE Socopo, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:205)

Diagnosis: Basal margins of elytra granular, weakly elevated; middle third of frons on median one-fourth shallowly concave, its lower margin armed by a transverse pair of small tubercles; declivital interstriae 2 rather strongly impressed, wider than 1 or 3, its surface smooth, polished.

Male: Similar to female except frontal tubercles slightly larger.

Female: Length 2.3–2.5 mm, 2.7 times as long as wide; color dark brown, almost black. Frons basically convex, except central third of median one-fourth rather deeply concave, lower margin of concavity (at level of antennal insertion) armed by a transverse pair of widely separated tubercles; surface reticulate, almost rugose, a few small granules in lateral and lower areas; punctures minute, obscure; vestiture of fine, sparse hair. Pronotum 1.2 times as long as wide; surface mostly dull, obscurely reticulate to minutely, longitudinally etched; punctures small, each 2–3 times as long as wide; almost glabrous except on anterior one-fourth. Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; striae weakly impressed, punctures small; interstriae almost three times as wide as striae, almost smooth, shining, punctures almost obsolete. Declivity steep, rather broadly sulcate; striae punctures minute, distinct; sutural interstriae slightly elevated, 2 strongly, broadly impressed, 3 abruptly, distinctly elevated on median side, devoid of granules, with fine uniseriate punctures except slightly confused on 2; vestiture confined to declivity, of interstitial rows of short bristles.

Distribution: Venezuela: 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 273, “Bejuco Blanco” (a liana), SLW.

Biology: Pith borers in small stems.

Notes: The above treatment was based on the holotype and allotype.

Cnesinus carbonarius Schedl

Cnesinus carbonarius Schedl, 1952:354. Holotype ♀; Brazil; NHMW, Wien (References in Wood & Bright c1992:206)

Diagnosis: Very similar to *alienus* Wood except distinguished by median line above female frontal concavity rounded, margin below concavity armed by a trans-

verse pair of tubercles; by the coarser, elongate punctures on the pronotum; and by the declivital sculpture.

Female: Length 2.7 mm, 2.9 times as long as wide; color dark reddish brown. Frons as in *alienus* except upper margin of frontal concavity armed by a median tubercle; lower margin of female concavity with several indefinite granules, vestiture shorter, less abundant. Pronotum 1.5 times as long as wide; similar to *alienus* except surface smooth, more brightly shining, punctures smaller, most as wide as long, larger especially on basal one-fourth; glabrous. Elytra 1.9 times as long as wide, 1.4 times as long as pronotum; as in *alienus* except striae less strongly impressed, striae punctures on disc smaller; striae punctures on declivity much larger, lateral convexities subacute.

Distribution: Brazil: “Brasilien, Koelle.”

Notes: The above treatment was based on the female holotype.

Cnesinus reticulus Wood

Cnesinus reticulus Wood, 1974:2. Holotype ♀; Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:211)

Diagnosis: Surfaces of head, pronotum, and elytra reticulate; punctures on basal third of pronotum large, close, shallow, those on anterior half much smaller, not as close.

Female: Length 1.9–2.0 mm, 2.5 times as long as wide; color very dark brown. Frons strongly concave from level of antennal insertion to vertex; surface reticulate, obscure, shallow punctures feebly subgranulate; vestiture sparse, fine, short. Pronotum 1.1 times as long as wide, feebly constricted on posterior half; surface reticulate on posterior half, becoming somewhat shagreened anteriorly, punctures very coarse, close, shallow on basal third, much smaller, elongate, more widely spaced on anterior half. Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; bases granular, obscurely subcrenulate; striae abruptly, weakly impressed, punctures confluent, subgranulate; interstriae almost flat, conspicuously reticulate, punctures minute, uniseriate (slightly confused on 2 and 3). Declivity steep, convex; striae and striae punctures obscure, interstriae 2 with a few obscure granules; vestiture restricted to declivity, of rows of erect interstitial bristles, each bristle about as long as two-thirds distance between rows, separated within a row by length of a bristle.

Distribution: Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 529, *Vismia cayennensis* twigs, SLW.

Notes: The above treatment was based on the holotype and on 1 paratype.

Cnesinus gracilis Blandford

Plate IX

Cnesinus gracilis Blandford, 1896:141. Holotype ♀; Volcan Chiriqui, Chiriqui, Panama; BMNH, London (Synonymy and references in Wood & Bright c1992:208)

Cnesinus substrigatus Blackman, 1943:376. Holotype ♀; Santander, Colombia; USNM, Washington
Cnesinus laetus Schedl, 1978:299. Holotype ♂; Corovado, Guanabara, Brazil; NHMW, Wien (References in Wood & Bright c1992:209).
New synonymy

Diagnosis: Among those species having the frons convex above the level of antennal insertion, this is the only species with a brush of moderately long hair over most of the frontal area.

Male: Similar to female except setae on frons shorter, less numerous, granules at summit of frons larger.

Female: Length 1.8–2.1 mm, 2.7 times as long as wide; color almost black. Frons transversely impressed (flat) on lower area, strongly, broadly convex above level of antennal insertion; surface subshining on impressed area, reticulate-granulate above, a few large granules on upper third; area from near epistoma to near upper level of eyes bearing an abundant brush of often reddish subplumose setae of uniform length, its length equal to about half width of an eye, most conspicuous in central area. Pronotum 1.1 times as long as wide; surface reticulate-granulate on posterior third, becoming rugose-reticulate by anterior fourth; punctures isolated, longitudinally elongate, about twice as wide on posterior fourth as on anterior fourth; subglabrous. Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; striae weakly impressed, punctures confluent on 1, clearly separate on 2–5, small; interstriae almost smooth, shining, about three times as wide as striae, punctures minute, uniseriate except slightly confused on 2 and 3. Declivity steep, broadly convex, somewhat flattened on lower half on interstriae 2–3; striae punctures deeper than on disc; interstriae 2 and 3 with a few granules on upper half; vestiture confined to declivity, of interstitial rows of moderately long, erect bristles, each slightly longer than distance between rows.

Distribution: Honduras to Colombia.

Brazil: Nova Teutonia, 27°11'N, 52°23'W, VII-1972, 300–500 m, F. Plaumann; Corcovado, Guanabara, IX-1969, Alvarenga & Seabra.

Colombia: Santander, Valle del Cauca, 700–1300 m, *Coffea arabica*, R.P. Roba.

Hosts: *Coffea arabica*, *Serjania* sp., etc. (not identified).

Biology: Axial pith tunnels were in stems up to 1 cm in diameter.

Notes: The above treatment was based on 40 specimens from Central America. Blackman identified the Colombian specimen (not seen by me) and on the male holotypes of *substrigatus* Blackman and *laetus* Schedl. The 2 Brazilian females were identified by Schedl incorrectly as of *carbonarius* Schedl; they are both 2.3 mm in length and have the declivital setae a bit more slender than is normal for this species.

Cnesinus minusculus Schedl

Cnesinus minusculus Schedl, 1952:353. Holotype ♀; Guyan. Ven. Mor.; NHMW, Wien (References in Wood & Bright c1992:209)

Diagnosis: Distinguished from *gracilis* Blandford by the absence of shagreening on the anterior parts of the pronotum; by the larger, shorter, more confluent punctures on the pronotum; and by the smaller interstitial punctures.

Female: Length 1.7 mm, 2.6 times as long as wide; color medium brown. Frons as in female *gracilis* except granules slightly larger, more widely, more uniformly scattered; surface almost rugose-reticulate. Pronotum 1.1 times as long as wide; similar to *gracilis* except with no shagreening, surface smooth, shining, punctures larger, oval to almost twice as long as wide, many on posterior half confluent; glabrous. Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; as in *gracilis* except interstitial punctures slightly larger (each about half as large as a striae puncture); disc glabrous. Declivity as in *gracilis* except erect interstitial setae slightly stouter.

Distribution: Venezuela (?): “Guyan. Ven. Mor.” [Handwritten in ink on dark blue-green paper of a kind regularly used by Eichhoff. Possibly it came from the Eichhoff Collection, through Eggers, to Schedl (Wood & Bright c1992:2–3)]. Because it came from Moritz in Venezuela, it could have been taken at Colonia Tovar near the Moritz home.

Notes: The above treatment was based on the female holotype.

Cnesinus acuminatus Schedl

Cnesinus acuminatus Schedl, 1978:298. Holotype ♀; Brasilien, Nova Teutonia, 300–500 m; NHMW, Wien (References in Wood & Bright c1992:205)

Diagnosis: Distinguished from all other species in this genus by the very small size; by the produced sutural apex of the elytra (not exactly acuminate), with the apices of the costal margin and of declivital interstriae 1 distinctly elevated.

Female: Length 1.5 mm, 2.6 times as long as wide; color very dark reddish brown. Frons shallowly, transversely impressed on lower half, convex above; surface minutely reticulate, rather dull; punctures minute, moderately numerous, uniformly distributed; vestiture of minute, inconspicuous hair, longer on epistomal margin. Pronotum 1.0 times as long as wide, widest at middle, anterior margin broadly rounded, sides on basal half weakly constricted; surface shining, moderately, closely, longitudinally strigose, punctures very small, most confluent; hairlike setae short, of fine hair near base, rather coarse on anterior fourth. Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; basal margin elevated into a row of basally contiguous crenulations, about nine weak, submarginal crenulations; striae distinctly, abruptly impressed, punctures rather coarse, most partly confluent, almost obsolete near declivity; interstriae convex, about as wide as striae, each with a row of shallow punctures, partly obscured by wrinkled surface, almost subcrenulate on basal fourth of disc. Declivity confined to posterior third of elytral length, broadly convex, steep,

apex moderately produced; striae narrower than on disc, punctures deeper; interstriae slightly wider than striae except 2, more strongly convex than on disc except 2 on lower half, crests with small, irregular rows of tubercles, lower 1 near apex more strongly elevated and continuing more strongly to apical portion of costal margin (not attenuate as interpreted by Schedl); obscurely emarginate at suture. Ground vestiture of fine, sparse, short hair on disc, coarser and apparently more abundant near and on declivity; clearly defined erect setae not evident although a few longer setae appearing to fill that role.

Distribution: Brazil: Nova Teutonia, Santa Catarina, VII-1975, 300–500 m, F. Plaumann.

Notes: The above treatment was based on the female holotype and on 1 female paratype, both from Brazil.

Cnesinus nitidus Eggers

Cnesinus nitidus Eggers, 1943:376. Lectotype ♂; Bolivia: Cochabamba; USNM, Washington, designated by Anderson & Anderson 1971:22 (References in Wood & Bright c1992:210)

Cnesinus discretus Wood, 1985:271. Holotype ♂; Rancho Grande, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:207). *New synonymy*

Diagnosis: Distinguished from *dividuus* Schedl by the more strongly convex frons, with moderately coarse granules at and below summit; and by the shorter interstitial setae on lateral areas of the elytral declivity.

Male: Length 2.3–2.4 mm, 2.9 times as long as wide; color very dark brown, prothorax almost black. Frons similar to *gracilis* Blandford except convexity begins lower, almost level of antennal insertion. Pronotum about as in *gracilis*. Elytra similar to *gracilis* except discal striae less strongly impressed, particularly 1; interstitial setae on declivity distinctly shorter, finer.

Distribution: Bolivia, Peru, Venezuela.

Bolivia: Cochabamba.

Peru: Almirante, San Martin, 12-XII-1936, 1900 m, F. Woytkowski; Rioja, San Martin, 25-XI-1936, F. Woytkowski.

Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 414, tree branch, SLW.

Biology: Removed from pith tunnels in twigs.

Notes: The above treatment was based on 3 males, 1 of which I compared to the lectotype of *nitidus* Eggers, a third specimen was the holotype of *discretus* Wood, a synonym.

Cnesinus dividuus Schedl

Cnesinus dividuus Schedl, 1938:22. Lectotype ♀; Buenos Aires, Tigre, Argentina; NHMW, Wien, designated by Wood 1985:267 (Synonymy and references in Wood & Bright c1992:207)

Cnesinus dryographus Schedl, 1951:78. Lectotype ♀; Nova Teutonia, Brazil; NHMW, Wien, designated by Wood 1985:267

Cnesinus laevicollis Schedl, 1951:79. Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, designated by Wood 1985:267

Diagnosis: Distinguished from *nitidus* Eggers by the smaller size; by the absence of granules on the frons;

and by the longer interstitial setae on the elytral declivity.

Male: Similar to female except a few fine granules present at and below summit of frons.

Female: Length 2.0–2.2 mm, 3.1 times as long as wide; color dark brown. Frons similar to *gracilis* Blandford except granules obsolete, setae very short, sparse, inconspicuous as in male. Pronotum similar to *gracilis* except punctures distinctly larger, closer. Elytra as in *gracilis* except basal crenulations slightly higher, striae 1 more strongly impressed; declivital setae much more slender, those on 3–5 conspicuously longer, some twice as long as distance between rows, those on 1 and 2 very slightly longer than distance between rows.

Distribution: Argentina to S Brazil.

Argentina: Buenos Aires, El Tigre.

Brazil: Nova Teutonia, Santa Catarina (27°11', 52°23'), IV-1950, 300–600 m, IV-1956, F. Plaumann; Agudos, Duraflora, Sao Paulo, ethanol trap, 20-XI-1984, *Pinus caribaea*, 25-III-1986, *Pinus oocarpa*, C.A.H. Flechtmann; Bocucatu, S.P., 25-IV-1990, ethanol trap in *Pinus*, *Eucalyptus* area, C.A.H. Flechtmann; MS: Tres Lagoas, CPC, Horto Barra do Moeda, ethanol trap, in *Eucalyptus grandis* stand, C.A.H. Flechtmann; MS: Selviria, UNESP Farm, 6-XI-1992, blacklight trap in *Brachiaria decumbens* pasture, C.A.H. Flechtmann; Telemaco Borba, Parana, 16-XI-2001, Klabin Papel e Cellulose, ethanol trap, *Pinus taeda* stand, C.A.H. Flechtmann.

Hosts: *Acacia nigra*.

Notes: The above treatment was based on 2 specimens from Argentina and 11 from Brazil. I compared 1 female directly to the female lectotypes of *dividuus* Schedl, *dryographus* Schedl, and *laevicollis* Schedl.

Cnesinus reticulatus (Chapuis)

Cnesinus reticulatus (Chapuis), 1869:29 (*Hylesinus*). Holotype ♀; Bogota [Colombia]; IRSNB, Brussels (References in Wood & Bright c1992:211)

Diagnosis: Dorsal margin of female epistomal callus armed by a closely set, transverse pair of tubercles; interstitial punctures numerous, confused; vestiture on pronotum and elytra slender, abundant; pronotum without crenulations.

Female: Length 3.1 mm, 2.6 times as long as wide; color reddish brown. Frons with upper third rather strongly convex, central area almost smooth, shining, lateral areas with confused hair; impressed below, epistomal margin continued as an acutely elevated crest less than half distance to upper level of eyes; epistomal callus smooth, shining, separated from epistomal margin only on lateral thirds by rows of small setiferous punctures, upper margin at median line elevated into a transverse pair of tubercles, upper slope of callus ornamented by a transverse double or triple row of reddish brown setae of uniform length. Pronotum 1.0 times as long as wide; median line subacutely costate on posterior two-thirds; surface coarsely, irregularly strigose, rugae irregular, shining, punctures confluent, not evident; vestiture of

abundant, fine, recumbent hair; coarser on all margins. Elytra 1.8 times as long as wide, 2.1 times as long as pronotum; striae 1 weakly, others not impressed, punctures very close; interstriae three to four times as wide as striae, densely covered by confused punctures, each puncture about half diameter of a strial puncture, surface shining. Declivity steep, broadly convex; striae 1 and 2 more deeply impressed, interstriae 2 distinctly impressed, punctures confused except uniseriate on lower half of 2; vestiture of abundant, fine, recumbent hair, coarser at sides and base of declivity.

Distribution: Colombia to Peru.

Colombia: Bogota.

Peru: Shishmay, Huanuco, 15-20-IX-1937, 3600–4100 m, highland lakes, F. Woytkowski.

Notes: The above treatment was based on the female holotype and on 1 female that I compared to the holotype of *reticulatus* (Chapuis).

Cnesinus excellens Wood, n. sp.

Cnesinus excellens Wood: Holotype ♀; La Rivera, Caicedonia, Valle de Cauca, Colombia; USNM, Washington, designated below

Diagnosis: Pronotum without crenulations; female epistomal callus armed by a median tubercle; eyes separated above by half width of an eye.

Male: Similar to female except epistomal elevation not evident, epistomal setae less conspicuous; setae on elytral declivity slightly longer.

Female: Length 1.7–1.9 mm, 2.9 times as long as wide; color dark brown, pronotum darker. Frons transversely impressed to distinctly above level of antennal insertion, evenly convex above; eyes coarsely faceted, separated above by half width of an eye; upper area of frons almost smooth, shining, glabrous, impunctate, lateral areas with a row of coarse setae at margin of eye almost to upper level of eye; epistomal elevation more than three-fourths as wide as lower frons, narrow (longitudinally), smooth, shining, its upper margin ornamented by a single row of yellowish brown setae of uniform length. Pronotum 1.2 times as long as wide; surface smooth, shining punctures small, isolated (not confluent), each 2–4 times as long as wide; vestiture of sparse, short hair confined to anterior third. Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; basal margins subacutely elevated into a continuous costa, striae distinctly impressed, those on 1 and 2 mostly confluent; interstriae almost twice as wide as striae, weakly convex, smooth, shining, minute punctures uniseriate, glabrous except rows of erect setae sometimes extending to basal fourth on 1 and 3. Declivity steep, convex; striae 1 and 2 rather deeply impressed, interstriae 1–3 narrowly convex, weakly elevated, 2 and 3 with indications of feeble granules; vestiture of uniseriate rows of erect slender bristles, those on 3–5 each twice as long as distance between rows, half as long on 1, intermediate on 2.

Distribution: Colombia (Valle de Cauca).

Type material: The female holotype, male allotype, and 5 paratypes were taken at La Rivera, Caicedonia, Valle del Cauca, Colombia, 18-VI-1959, J. Restrepo. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Hosts: “Guamo verde.”

Biology: “En ramitas.”

Cnesinus elegans Blandford

Cnesinus elegans Blandford, 1896:140. Lectotype ♀; Guatemala: Cerro Zunil; BMNH, London, designated by Wood 1982:226 (References in Wood & Bright c1992:207–208)

Diagnosis: Distinguished by the widely spaced transverse pair of tubercles on the female epistomal callus; by the yellowish epistomal row of setae; and by the uniseriate interstitial punctures.

Male: Similar to female except epistomal callus smaller and without tubercles; declivital impression slightly deeper.

Female: Length 2.4–2.8 mm, 2.9 times as long as wide; color very dark reddish brown, pronotum often almost black. Frons convex on upper half, impressed (transversely flat) below, lateral margins subacute, their dorsal end at ocular situation; epistomal callus poorly formed, armed by transverse pair of moderately spaced, small tubercles; surface minutely reticulate-granulate, fine punctures obscure; vestiture consisting of a row of moderately coarse, rather long setae on upper slope of epistomal callus and on lateral margins to upper level of eyes; eyes separated above by 1.7 times width of an eye. Pronotum 1.17 times as long as wide; setae confined to anterior fourth, surface shining; punctures rather fine, deep, most elongate, at least half confluent with at least 1 other puncture. Elytra 1.9 times as long as wide, 2.0 times as long as pronotum; crenulations on basal margins clearly formed; striae 1 moderately, others weakly impressed, punctures rather small, moderately deep, confluent on 1; interstriae 1 and 2 slightly wider than striae, 3 and 4 twice as wide as striae, surface almost smooth, minute punctures uniseriate except moderately confused on 2 and 3, with rows of fine granules near declivity. Declivity convex, steep, slightly impressed between interstriae 3; striae 1 moderately impressed, interstriae 1 weakly convex, 3 and 4 each with a row of fine granules; interstitial vestiture confined to declivity except sparse on 1 and 3 to middle of disc, a few supplemental, shorter setae on declivity, each bristle slightly longer than distance between rows.

Distribution: Mexico (Veracruz) to Colombia (?) and Venezuela. The South American specimens reported by Schedl (1940:331), were not seen by me.

Colombia: Santander (Blackman 1943:376).

Brazil: Nova Teutonia, Santa Catarina 27°11'N, 52°23'W, VI-1972, F. Plaumann.

Hosts: *Arbutus*, *Rubus*, *Serjania* (not identified to species).

Biology: Taken from pith tunnels in twigs.

Notes: The above treatment was based on 41 specimens from Mexico to Honduras, some of which I compared to the holotype.

Cnesinus colombianus Wood

Plate VIII

Cnesinus colombianus Wood, 1967:84. Holotype ♀; El Bosque, Caicedonia, Valle del Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:206)

Diagnosis: Distinguished by the absence of pronotal crenulations; by the presence of numerous, confused interstitial punctures; by the larger size; and by the different female epistomal elevation.

Male: Similar to female except epistomal callus poorly formed, brush much smaller, yellowish.

Female: Length 2.8–3.0 mm, 2.3 times as long as wide; color dark reddish brown. Frons with upper half to just above eyes smooth, shining, a few minute punctures in lateral areas; lower half transversely impressed, lateral margins acute; epistomal callus with lower margin marked by a row of setiferous punctures except absent on median one-fifth, upper margin and impressed area bearing a large brush of reddish brown setae of uniform length; vertex punctate-rugose, transition to smooth frontal area abrupt; eyes rather widely separated above. Pronotum 0.95 times as long as wide; resembling *elegans* except median half on posterior two-thirds coarsely, deeply strigose. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae narrowly, moderately impressed, punctures small, distinct, close, not confluent; interstriae about twice as wide as striae, smooth, shining, punctures rather small, abundant, confused; glabrous. Declivity convex, rather steep, feebly impressed on interstriae 2; striae 1 and 2 more deeply impressed, interstitial punctures more nearly uniseriate; glabrous except at sides.

Distribution: Colombia: El Bosque, Caicedonia, Valle del Cauca, 23-VI-1959, matapalos, J. Restrepo.

Notes: The above treatment was based on the type series of 26 specimens. In the original description of this species the sexes were reversed.

Cnesinus pusillus Schedl

Cnesinus pusillus Schedl, 1948:267. Holotype ♀; Blumenau, Brazil; NHMW, Wien (References in Wood & Bright c1992:211)

Diagnosis: Distinguished by the striae and interstitial rugose-reticulate to densely micropunctured surfaces; by the conspicuous rows of small, striae punctures; and by the small size.

Male: A male, presumed to be this species (Nova Teutonia, in Eberswalde collection), has the discal interstriae smooth, shining; epistomal callus reduced, brush yellowish, with one row of setae.

Female: Length 1.7 mm, 2.5 times as long as wide; color dark reddish brown. Frons with epistomal callus broad, short, brush on its upper slope rather large,

about 3–5 ranks deep; transverse impression restricted to lower half, large, central, shining, impunctate area extending to upper level of eyes, a sparse brush of long setae at sides and above. Pronotum 1.0 times as long as wide; surface shining, finely, rather closely strigose on anterior two-thirds, more coarsely on basal third; vestiture of fine, moderately abundant, rather short hair. Elytra 1.6 times as long as wide, 1.8 times as long as pronotum; bases of elytra almost with a continuous costa, crenulations obscure; striae distinctly impressed, punctures obscure, lost through confluence, surface rugose-reticulate; interstriae distinctly wider than striae, with dense micropunctures (rugose-reticulate in some areas), punctures fine, uniseriate. Declivity broadly convex, rather steep; striae 1 to 3 less strongly impressed than on disc, punctures deeply impressed, much larger; interstriae 1 to 3 weakly, about equally convex, each with a uniseriate row of punctures to apex. Vestiture mostly on declivity except extending to base on interstriae 1; on declivity consisting of rows of fine, short striae hair and, on interstriae of a few fine, short ground setae and rows of closely placed erect bristles, each bristle as long as distance between rows, separated within a row by about half that distance.

Distribution: Brazil: Blumenau (Santa Catarina).

Notes: The above treatment was based on the female holotype and on 1 female paratype.

Cnesinus gibbus (Chapuis)

Cnesinus gibbus (Chapuis), 1869:28 (*Nemophilus*). Holotype ♀; Cumana [Venezuela]; IRSNB, Brussels (References in Wood & Bright c1992:208)

Diagnosis: Distinguished from *sulcatus* Eggers by the visible declivital striae 1 and 2, with interstriae 2 strongly narrowed (but present) and devoid of setae.

Female: Length 2.4 mm, 2.5 times as long as wide; color dark reddish brown. Frons apparently similar to *sulcatus* except epistomal callus wider (head detached, partly obscured by glue and resin). Pronotum 1.02 times as long as wide; moderately strigose on anterior third, rather coarsely strigose on middle third (crests narrower than grooves), crests shorter on posterior third, some grooves short enough to resemble punctures; sparse setae on margins. Elytra 1.6 times as long as wide, 1.8 times as long as pronotum; rather coarse submarginal crenulations at bases of interstriae 2–5; striae weakly impressed, punctures rather coarse, moderately deep, not confluent; interstriae about twice as wide as striae, smooth, shining, somewhat wrinkled, punctures small, modestly confused on 2–5, no granules. Declivity broadly convex, steep; striae at base more strongly impressed than on disc, punctures confluent, obscurely visible to apex; interstriae 1 narrower, feebly elevated, with punctures to apex, 2 equally narrow on upper half, obsolete on lower third, with uniseriate punctures on basal half, with setae on basal third, middle third very weak, without

punctures or setae. Vestiture on disc mostly lost through abraisment, stout interstitial setae confused on interstriae 3–5, uniseriate on 1, each about two-thirds as long as distance between rows; setae almost scalelike on declivity (each about 5 times as long as wide), apparently confused on basal third on 2–6, apparently uniseriate below (most lost through abraisment).

Distribution: Venezuela: Cumana, Deyrolle.

Notes: The above treatment was based on the female holotype.

Cnesinus bispinatus Schedl

Cnesinus bispinatus Schedl, 1976:62. Holotype ♂; "Alte sammlung Brasilien"; NHMW, Wien (References in Wood & Bright c1992:206)

Diagnosis: This species is not in the above key. Because only the male holotype is known, the exact position of this species in classification is not clear. It appears to be most closely allied to *gibbus* (Chapuis) among known species. It is distinguished from all other known members of this genus by the pair of spines that project from the apices of the elytra.

Male: Length 1.7–1.9 mm, 2.7 times as long as wide; color dark reddish brown, pronotum darker. Frons moderately, transversely impressed on lower half; epistomal callus obscure to absent, a row of setae associated with callus not evident; upper half of frons rather strongly convex, reticulate, impunctate and glabrous on median half; vestiture moderately long, coarse, about evenly distributed on lower half and on lateral areas above; both antennae missing from type. Pronotum 1.1 times as long as wide, widest slightly in front of middle; surface shining, longitudinally strigose, punctures rather coarse, deep, mostly confluent, ridges half as wide as punctures; vestiture on basal third short, fine, longer and coarser anteriorly. Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; basal margins armed by a row of low crenulations; striae narrowly, abruptly, moderately impressed, punctures small, rather obscure, mostly confluent; interstriae smooth, shining, almost twice as wide as striae, punctures uniseriate, shallow, rather large. Declivity broadly convex, rather steep; striae slightly deeper than on disc, interstriae narrower than on disc, each armed by a row of 10 or more small, pointed denticles; apex at suture prolonged into a conspicuous, tapered spine longer than its basal width. Vestiture confined to declivity, consisting of rows of minute, fine strial hair, and interstitial rows of erect, distinctly flattened bristles, each bristle equal in length to distance between rows; disc with very short, fine, minute interstitial hair.

Distribution: Brazil: "Alte sammlung Brasilien"; Agudos, Sao Paulo, 14-X-1986, Duraflora, SA, ethanol trap, *Pinus oocarpa* stand, C.A.H. Flechtmann; Code 090, R.A. Beaver (presumably in Mato Grosso).

Notes: The above treatment was based on the holotype, apparently a male, and on 2 other males.

Cnesinus foratus Wood

Cnesinus foratus Wood, 1967:81. Holotype ♀; El Bosque, Caicedonia, Valle del Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:208)

Diagnosis: Distinguished by the more coarsely strigose pronotum which is almost equal in length and width; by the uniseriate interstitial punctures, with setae extending to base on interstriae 2 and 4.

Male: Similar to female except epistomal callus more poorly formed, setae on upper slope less numerous, yellowish.

Female: Length 2.0–2.1 mm, 2.4 times as long as wide; color dark brown. Frons convex above level of ocular sinuation, obscurely subreticulate, impunctate, strongly, transversely impressed below; epistomal callus smooth, shining, its lower margin marked by a row of very small setiferous punctures almost to median line, upper slope ornamented by a double row of reddish brown setae of moderate length, lateral margins subacute to above level of antennal insertion; eyes separated above by twice width of an eye. Pronotum 1.04 times as long as wide; surface coarsely, shallowly punctured, almost all punctures longitudinally confluent, ridges occupying less than one-third of surface; vestiture restricted to margins (extending to base in some specimens), coarse, rather short, sparse. Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; striae impressed, punctures on 1 and 2 entirely confluent, others subconfluent but distinct; interstriae slightly wider than striae, shining, almost smooth, fine punctures irregular, almost uniseriate. Declivity convex, steep; weakly impressed at striae 2, a few minute granules on interstriae 1–4; vestiture of erect interstitial bristles (a few shorter supplemental interstitial setae on declivity), bristles extend almost to base on 1 and 2, others to middle of disc; bristles rather stout, equal in length to distance between rows, spaced within a row by length of a bristle.

Distribution: Colombia: El Bosque, Caicedonia, Valle del Cauca, 23-VI-1959, matapalos, J. Restrepo.

Hosts: "En matapalos y ramas de cafe."

Biology: In pith tunnels of twigs and small branches.

Notes: The above treatment was based on the type series of 17 specimens and on 4 other specimens. The holotype is a female, not a male as originally stated.

Cnesinus deperditus Wood

Cnesinus deperditus Wood, 1974:4. Holotype ♀; Piedras Blancas, 10 km E Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:207)

Diagnosis: Distinguished from *foratus* Wood by the larger size; by the very different epistomal callus and brush; and by the more slender body form.

Female: Length 2.5–2.7 mm, 2.65 times as long as wide; color dark reddish brown. Frons similar to *foratus* except upper area uniformly more strongly reticulate, epistomal callus with gap in row of punctures at lower

margin larger, equal to almost one-fifth width of lower frons, epistomal brush on upper slope of callus more extensive (about 4 rows of setae). Pronotum 1.1 times as long as wide; median line subcarinate on posterior two-thirds; surface more finely strigose, ridges narrower, less extensive. Elytra 1.9 times as long as wide, 2.1 times as long as pronotum; striae deeply, abruptly impressed; punctures confluent; interstriae twice as wide as striae, obscurely rugulose, fine punctures uniseriate on 1, moderately confused on 2–4. Declivity convex, steep; resembling *foratus*; vestiture of erect bristles extending to base on all interstriae, moderate supplemental setae on declivity; bristles more slender than in *foratus*, slightly shorter, closer within a row.

Distribution: Colombia: Piedras Blancas 10 km E Medellin, Antioquia, 15-VII-1970, 2500 m, No. 685, *Quercus humboldtii*, SLW.

Biology: Taken from pith tunnels in twigs.

Notes: The above treatment was based on the type series of 2 females.

Cnesinus schoenherri Schedl

Cnesinus schoenherri Schedl, 1976:63. Holotype ♀; Brasilien, Rio Negrinho; NHMW, Wien (References in Wood & Bright c1992:211)

Diagnosis: Distinguished from *sulcatus* Eggers by the smaller size; by the obsolete striae; and by details of sculpture on the elytral declivity.

Female: Length 3.0–3.2 mm, 2.5 times as long as wide; color dark reddish brown. Frons with epistomal callus smooth, shining, rather weakly developed, reddish brown brush on its upper slope broad, of about 3 ranks of setae; frontal impression extending from brush six-sevenths of distance to upper level of eyes, rather strongly concave, its lateral and dorsal margins ornamented by long, rather abundant setae, floor of concavity dull, almost glabrous. Pronotum 0.96 times as long as wide; surface closely, longitudinally strigose, punctures not evident, sulci and crests unusually long; almost glabrous. Elytra 1.8 times as long as wide, 2.0 times as long as pronotum; striae 1 and 2 not impressed, 3–9 weakly impressed, punctures minute, shallow, interstriae smooth shining, punctures minute, not close, confused. Declivity rather steep, moderately sulcate between left and right striae 3; striae 1 and 2 flat, smooth, shining, punctures obsolete, 3 moderately elevated and costate from base to apex, 4 to 9 moderately convex before apex. Vestiture on disc small to minute, longer toward declivity; declivital interstriae 3–9 each with a row of moderately long, slender bristles.

Distribution: Brazil: Rio Negrinho, Santa Catarina, III-1972, B48, J. Schoenherr; Monte Alegre, Para, 18-VII-1997, ethanol trap, C.A.H. Flechtmann; Telemaco (Sao Paulo?), 20-XII-1996, ethanol trap, *Pinus taeda* stand, C.A.H. Flechtmann.

Notes: The above treatment was based on the female holotype and on 1 female paratype.

Cnesinus sulcatus Eggers

Cnesinus sulcatus Eggers, 1931:34. Holotype, sex?; Sao Paulo (Brasil); NMPC, Prague (References in Wood & Bright c1992:212)

Cnesinus novateutonicus Schedl, 1951:77. Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:210). *New synonymy*

Diagnosis: Distinguished from *schoenherri* Schedl by the smaller size; by the weakly elevated and punctured declivital interstriae 1; by the more strongly elevated epistomal callus; and by other characters described below.

Male: Similar to female except epistomal brush reduced to about a 2-ranked row of yellowish setae, other frontal setae shorter, half as numerous; elytral setae apparently finer, slightly longer.

Female: Length 2.0–2.3 mm, 2.3 times as long as wide; color dark reddish brown. Frons with epistomal callus smooth, shining on median one-third, brush on its upper slope about 3-ranked, broad, moderate, transverse impression on slightly more than lower half of area below upper level of eyes, smooth, shining, impunctate area extending from upper margin of eyes to deepest part of impression, lateral and upper margins with a sparse fringe of rather short setae. Pronotum 1.03 times as long as wide; surface shining, rather coarsely, longitudinally strigose, grooves moderately long; vestiture short, hair-like, moderately abundant. Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; striae abruptly, slightly impressed, often mostly reticulate-granulate, punctures obscure to obsolete in some specimens; interstriae slightly wider than striae, smooth, shining, punctures moderately coarse, close, confused. Declivity rather steep, shallowly bisulcate; interstriae 1 weakly elevated, with a central row of punctures to apex, striae 1 and 2 and interstriae 2 flat, forming a smooth polished, impressed surface with a few fine punctures (evidently derived from interstriae 2); interstriae 3 rather strongly, narrowly elevated on a continuous costa from base to apex, 3–9 weakly convex, each with a row of punctures. Vestiture on disc of short, sparse, fine hair, longer toward and on declivity, in uniseriate rows on declivital interstriae except absent on 2.

Distribution: Brazil: Parana, Bocaiuva, 25°08' B, 49°04' L, 1000 m; Sao Paulo, Mraz lgt., Mur. Pregenae; Nova Teutonia, Santa Catarina, 20-V-1935, II-1937, 16-V-1949, VIII-1966, VIII-1978, F. Plaumann; Aguidos, Duraflora, S.P., 2-IX-1986, ethanol trap, *Pinus oocarpa* stand, C.A.H. Flechtmann, also 4-IX-1986, *P. c. caribaeae* trap; Telemaco Borba, 21-X-2000, 12-I-2001, 10-XI-2000, 23-II-2001, ethanol trap, *Pinus taeda* stand, C.A.H. Flechtmann.

Hosts: *Canella* sp.

Notes: The above treatment was based on 2 female cotypes of *sulcatus*, on the female labeled by Schedl as the “holotype” of *C. novateutonicus* Schedl, and on 4 other specimens in the Schedl series and 2 males and 1 female from Brazil. Because *C. novateutonicus* Schedl was based on a syntypic series, Schedl’s subsequent

designation of a holotype was invalid. That "holotype" is here designated as the lectotype of *C. novateutonicus* Schedl, a junior synonym of *sulcatus*.

Cnesinus grandis Schedl

Cnesinus grandis Schedl, 1935:273. Holotype ♀; Brazil; NHMW, Wien (References in Wood & Bright c1992:209)

Diagnosis: This species is distinguished from other members of the genus by the large size; by the replacement of punctures by rounded tubercles on the basal median half of the pronotum; and by the rugose-reticulate discal striae that have no punctures.

Female: Length 3.7 mm, 2.5 times as long as wide; color dark reddish brown. Frons broadly convex above, rather strongly, transversely impressed on lower half; epistomal callus broad, short (longitudinally), smooth, brightly shining, its dorsal slope ornamented by a reddish brown brush (about three ranks) of laterally compressed setae of uniform length; from deepest point of impression a one-fourth circle smooth, shining, glabrous convexity extends dorsad to distinctly above upper level of eyes, area below this convex area dull, with a few minute punctures and short, sparse setae; transition above eyes abrupt from shining area to vertex, rugose-reticulate above. Pronotum 1.0 times as long as wide; sides on basal two-thirds straight, diverging slightly cephalad; anterior half and lateral fourths of surface with fine, shallow, mostly confluent punctures, areas within punctures strongly reticulate, between punctures smooth, shining; median half on basal half coarsely reticulate, with rounded, shining granules of irregular shape; vestiture of moderately abundant, long, very fine hair (apparently shorter in lateral areas). Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; striae distinctly impressed, punctures entirely obsolete, surface rugose-reticulate from base to base of declivity; interstriae slightly wider than striae, smooth, shining, with fine, dense, confused punctures. Declivity broadly convex, shallowly sulcate below, rather steep; striae smooth, shining, punctures very small, rather deep, not easily distinguished from those of interstriae. Vestiture of fine hair, moderately long on disc, longer, coarser, and mostly in uniseriate rows on declivity. Visible sternum 5 with a moderately large, deep concavity near its center.

Distribution: Brazil: "Brasilien."

Notes: The above treatment was based on the female holotype.

Cnesinus schulzi Wood, n. sp.

Cnesinus schulzi Wood: Holotype ♂; Jodensavanne Kamp 8, Suriname; USNM, Washington, designated below

Diagnosis: Distinguished by the small size; by the coarse, slightly elongate (not at all strigose) punctures on the basal half of the pronotum, punctures much smaller anteriorly; and by the uniseriate interstitial bristles on the declivity.

Male: Length 1.8 mm, 2.4 times as long as wide; color dark reddish brown, pronotum darker. Frons covered by glue, apparently similar to male *foratus*. Pronotum 1.04 times as long as wide; basal third rather coarsely punctured, punctures moderately deep, separate, mostly less than twice as long as wide, half as large and more elongate before attaining anterior third; surface smooth, shining on basal half, dull anteriorly; a few stout setae on anterior fourth. Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; basal margins subacutely elevated; striae modestly impressed, punctures rather coarse, subconfluent; interstriae about as wide as striae, almost smooth, shining, fine punctures uniseriate. Declivity convex, steep; striae 1 and 2 distinctly impressed, punctures reduced in size, interstriae without granules; vestiture of rows of interstitial bristles, restricted to declivity except on 1 and 3 extending almost to base.

Distribution: Suriname.

Type material: The male holotype was labeled Craigthorp 1961, Jodensavanne, Kamp 8 [Suriname], lectv., Schulz, 58. The holotype is in the USNM, Washington.

Cnesinus bicolor Eggers

Cnesinus bicolor Eggers, 1943:376. Holotype ♀; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:206)

Diagnosis: Distinguished by the slender form; by the fine, long, hairlike interstitial setae; by the non-strigose pronotal setae; and by the distinctive female epistomal elevation.

Male: Similar to female except epistomal elevation smaller, poorly defined, its upper slope with one row of setae.

Female: Length 2.5–2.7 mm, 2.7 times as long as wide; color reddish brown. Frons somewhat resembling *foratus* Wood, epistomal elevation rather large, smooth, shining, lower margin not sharply defined, short row of fine punctures on lateral thirds, shining area separate from margin, median third not separated from epistomal lobe, upper margin of callus sharply, obtusely defined, reddish brown band of setae on epistoma 2-ranked, as wide as elevated area. Pronotum 1.1 times as long as wide; surface smooth, shining, small punctures separate, rarely confluent, each about twice as long as wide near base, up to 4 times as long as wide on anterior half; margins with long, slender setae. Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; basal margins with low crenulations; striae 1 moderately, others weakly impressed, punctures distinct, spaced within a row by diameter of a puncture; interstriae twice as wide as striae, surface smooth, shining, small punctures of irregular size, almost uniseriate. Declivity convex, steep, shallowly impressed between left and right interstriae 3; striae 1 impressed, punctures not evident; interstriae without granules; vestiture of interstitial rows of fine, long, hairlike setae, each one and one-half times as long

as distance between rows, spaced within a row by half length of a seta.

Distribution: Bolivia to Peru.

Bolivia: Cochabamba.

Peru: Shishmay, Dep. Huanuco, 15-20-IX-1937, 3600–4100 m, highland, F. Woytkowski.

Notes: The above treatment was based on 1 female that I compared directly to the holotype, and 1 on male.

Cnesinus fulgens Wood

Cnesinus fulgens Wood, 1974:4. Holotype ♂; La Carbonera Experimental Forest, 50 km airline NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:208)

Diagnosis: Distinguished from *bisulcatus* Schedl by the slightly larger punctures on the slightly reticulate pronotum; by the more deeply impressed discal striae; and by the shorter elytral setae.

Male: Similar to female except epistomal callus and brush smaller, more poorly developed; upper frons finely reticulate.

Female: Length 2.5–2.9 mm, 2.7 times as long as wide; color reddish brown. As in *bisulcatus* except: frontal callus wider; larger; upper frons smooth, shining; pronotum obscurely reticulate on basal third, punctures distinctly larger; all striae more distinctly impressed; declivital interstitial setae distinctly shorter (very slightly longer than distance between rows).

Distribution: Venezuela: La Carbonera Experimental forest 50 km NW Merida, Merida, 14-XI-1969, 2500 m, No. 136, *Rubus*, SLW; La Mucuy Experimental Forest, 20 km NE Merida, Merida, 22-XII-1969, 2500 m, No. 205, *Rubus*, SLW.

Biology: Taken from pith tunnels in small stems.

Notes: The above treatment was based on the type series of 59 specimens.

Cnesinus bituberculatus Schedl

Cnesinus bituberculatus Schedl, 1966:102. Holotype ♀; Brasilien, Nova Teutonia; NHMW, Wien (References in Wood & Bright c1992:206)

Diagnosis: Distinguished from *bisulcatus* Schedl by the smaller size; by the oval, non-strigose punctures on the pronotum; by the narrower epistomal callus, with the lower margin more strongly procurved.

Female: Length 2.1 mm, 2.6 times as long as wide; color dark reddish brown. Frons resembling *bisulcatus* except epistomal brush less extensive, smooth area on callus less dull, narrower, lower margin more strongly procurved. Pronotum with punctures oval, usually not strigose, less numerous. Striae less strongly impressed, punctures slightly larger. Declivital interstitial striae 1 subglabrous, 2 and 3 each with a row of very closely set, course bristles inclined toward suture in both species.

Distribution: Brazil: Rondon, Parana, 2-X-1952, F. Plaumann.

Notes: The above treatment was based on the female holotype of *C. bituberculatus* Schedl. Schedl incorrectly

labeled the holotype as a male. It is a female. Schedl's "allotype" is an incorrectly identified specimen of *C. plaumanni* Schedl.

Cnesinus bisulcatus Schedl

Cnesinus bisulcatus Schedl, 1948:266. Holotype ♀; Colombia; NHMW, Wien (References in Wood & Bright c1992:206)

Diagnosis: Female epistomal callus narrower (transversely), only its lower fourth smooth and shining; interstitial setae very slender, striae setae on declivity small, conspicuous.

Male: Similar to female except epistomal callus poorly formed.

Female: Length 2.4–2.7 mm, 2.7 times as long as wide; color brown. Upper frons with eyes spaced above by 1.5 times width of an eye; lower margin of epistomal callus usually abrupt, median unpunctured space in row of setiferous punctures at its lower margin equal to about one-eighth width of lower frons, brush on upper slope rather small, setae about 4-ranked; upper area strongly reticulate; lateral vestiture sparse. Pronotum 1.1 times as long as wide; punctures small, close, each about twice as long as wide on basal fourth, four times as long as wide on anterior third, few confluent near base, half confluent on anterior third; vestiture of fine, short hair on anterior fourth, a few setae on lateral margins. Elytra 1.8 times as long as wide, 2.0 times as long as pronotum; basal margins with feeble crenulations indicated; interstitial striae 1 moderately, others very weakly impressed, punctures small, distinct, close; interstitial striae 2–3 times as wide as striae, surface almost smooth, shining, fine punctures almost uniseriate except moderately confused on 2 and 3 in some specimens. Declivity convex, steep; striae 1–3 moderately impressed, punctures obscure to obsolete on 1, interstitial striae 1–3 convex, 3 slightly higher; vestiture absent on lower half or more of interstitial striae 1, longest on 2–4, slender, longest setae twice as long as distance between rows and between setae within a row, recumbent striae setae present on declivity very fine, short, up to half length of erect bristles; some erect bristles extend to or beyond middle of disc on some interstitial striae.

Distribution: Colombia to Venezuela.

Colombia: Exact locality not given.

Venezuela: Colonia Tovar, Aragua, 4-IV-1970, 1700 m, No. 505, Bignoniaceae liana, No. 509, cut tree seedlings, SLW.

Biology: Taken from pith tunnels in small twigs.

Notes: The above treatment was based on 16 specimens; 1 female of which I compared directly to the holotype.

Cnesinus meris Wood

Cnesinus meris Wood, 1982:226. Holotype ♀; La Cumbre, Valle de Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:209)

Diagnosis: Smooth, shining area on epistomal callus large, brush on its upper slope smaller; lateral thirds of

pronotum longitudinally microstrigose (longitudinally etched reticulation); lower half of declivital interstriae 1 without setae.

Male: Similar to female except epistomal callus and brush smaller, more poorly formed.

Female: Length 2.2–2.5 mm, 2.7 times as long as wide; color very dark brown, pronotum darker. Frons with eyes spaced above by 1.1 times width of an eye; frons on upper half smooth, shining, with a few minute punctures; epistomal callus somewhat resembling *bisulcatus* Schedl, its lower margin abrupt, shining area triangular, twice as wide as high, brush on its upper slope small, about three ranks deep. Pronotum 1.1 times as long as wide; punctures small, rather close, on basal fourth each twice as long as wide, 4 times as long as wide on anterior third; surface of lateral thirds and anterior third longitudinally microstrigose; glabrous. Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; basal margins slightly elevated into a continuous costa; striae narrowly, distinctly impressed, punctures small, close, some confluence; interstriae smooth, shining, almost three times as wide as striae. Declivity convex, steep; striae 1–3 impressed, punctures larger than on disc; interstriae 1–3 modestly convex, smooth, shining, each with a row of small punctures, no granules; erect interstitial setae restricted to declivity, each somewhat stout, about as long as distance between rows, spaced within a row by half this distance; striae hair distinct, inconspicuous.

Distribution: Colombia: La Cumbre, Valle del Cauca, 3-VI-1959, en cafe, N. Munoz; El Pino, Valle del Cauca, en cafe, I. Parra.

Hosts: *Coffea arabica*.

Notes: The above treatment was based on the type series of 14 specimens.

Cnesinus fulgidus Wood

Cnesinus fulgidus Wood, 1974:5. Holotype ♂; Piedras Blancas 10 km E Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:208)

Diagnosis: Distinguished from *triangularis* Wood by the female frontal callus half as wide as lower frons, smooth area wider than long; by the smooth, shining pronotum over the basal three-fourths; and by the host.

Male: Similar to female except epistomal callus and brush smaller, more poorly formed.

Female: Length 2.3–2.5 mm, 2.6 times as long as wide; color brown, pronotum darker. Frons similar to *meris* Wood except shining area on female epistomal callus 3 times as wide (transversely) as long. Pronotum 1.1 times as long as wide, with punctures very small, each slightly longer than wide on basal fourth, twice as long as wide on anterior third, not close; surface smooth, shining, almost glabrous. Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; striae 1 moderately, others weakly impressed, punctures small, close, distinct; interstriae about three times as wide as striae, surface almost

smooth, shining, minute punctures uniseriate. Declivity convex, smooth, moderately impressed between left and right interstriae 3, striae 1 narrowly impressed, punctures mostly obsolete, 2 not impressed, punctures distinct; interstriae 3 narrowly convex with obscure granules on crest, vestiture confined to declivity, fine, sparse mostly rubbed off, absent on interstriae 1 and 2.

Distribution: Colombia: Piedras Blancas 10 km E Medellin, Antioquia, 15-VII-1970, 2500 m, No. 685, *Quercus humboldtii*, SLW.

Biology: Taken from pith tunnels in small twigs.

Notes: The above treatment was based on the type series of 57 specimens.

Cnesinus triangularis Wood

Cnesinus triangularis Wood, 1974:5. Holotype ♀; Piedras Blancas 10 km E Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:212)

Diagnosis: Female epistomal callus narrow, less than half as wide as lower frons, shining area triangular, as high as wide.

Male: Similar to female except epistomal callus and brush reduced in size, poorly formed.

Female: Length 2.1–2.5 mm, 2.7 times as long as wide; color very dark brown, almost black. Frons similar to *fulgidus* Wood except smooth, shining part of epistomal callus occupying median third, triangular, as high as wide. Pronotum 1.13 times as long as wide; surface smooth, shining; punctures separate on basal fourth, each about twice as long as wide, on anterior half 2 or more often confluent, each about 4 times as long as wide; vestiture of fine, short hair on anterior third. Elytra 2.0 times as long as wide, 2.05 times as long as pronotum; basal margins armed by very small, feeble crenulations; striae 1 moderately, others weakly impressed, punctures on 1 partly confluent, separate on others; interstriae almost smooth, brightly shining, punctures very small, mostly uniseriate (some slightly confused on basal half). Declivity convex, steep, moderately impressed between left and right interstriae 3; striae 1 and 2 impressed, their punctures mostly obsolete; interstriae each with a row of fine punctures; vestiture of rows of slender interstitial bristles mostly on declivity, absent on lower half of 1, extending almost to base on 1, a few on 2–4; longest bristles on 2–4, each slightly longer than distance between rows, spaced within a row by half that distance; minute striae setae present on declivity.

Distribution: Colombia: Piedras Blancas 10 km E Medellin, Antioquia, 15-VII-1970, 2500 m, No. 656, from twigs of “Uvo de Monte” shrub, SLW.

Biology: Taken from pith tunnels in twigs.

Notes: The above treatment was based on the type series of 90 specimens.

Cnesinus squamifer Wood, n. sp.

Cnesinus squamifer Wood: Holotype ♂; San Pedro de Colalao, Tucuman, Argentina; USNM, Washington, designated below

Diagnosis: This species is distinguished from all other members of the genus by the dense covering of large, broad, pale scales on both pronotum and elytra; anterolateral area of pronotum armed by a row of 6 crenulations; sutural apex slightly divaricate; frontal impression weakest in this genus.

Male (?): Length 2.2 mm, 2.7 times as long as wide, color brown, scales pale. Frons with lower half very shallowly impressed (transversely flat), epistomal callus poorly formed, its upper slope marked by only 1 row of reddish brown setae; upper half convex, smooth, impunctate as in most species of this genus. Pronotum 1.06 times as long as wide; anterolateral areas each armed by an almost longitudinal row of 6 crenulations; surface obscured by recumbent setae, apparently rather closely, coarsely, deeply punctured; surface covered by ground cover of oval scales, each slightly longer than wide, and less abundant, short, stout recumbent bristles each about 6–8 times as long as wide. Elytra 1.8 times as long as wide, 2.0 times as long as pronotum; basal margins each armed by a row of about 11 rather coarse crenulations; striae narrowly, distinctly impressed, small punctures distinct, not confluent; interstriae covered by ground cover of rather large, oval, recumbent scales, each slightly longer than wide; each interstriae with a central row of small setiferous tubercles, each bearing a stout, erect bristle (about 8 times as long as wide), equal in length to two-thirds of distance between rows, spaced within a row by 1–3 times length of a bristle. Declivity convex, rather steep; somewhat flattened between left and right interstriae 3, 2 slightly impressed; sutural apex distinctly emarginate, apices of elytra distinctly divaricate (reminiscent of *squamosus*, but apparently unrelated).

Distribution: Argentina.

Type material: The male holotype was taken at San Pedro de Colalao, Tucuman, Argentina, 21-IV to 13-V-1968, malaise trap, L. Stange. The holotype is in the U.S. National Museum, Washington.

Cnesinus hispidus Eggers

Cnesinus hispidus Eggers, 1943:378. Holotype, sex?; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:209)

Diagnosis: Distinguished by crenulations on the anterolateral areas of the pronotum, by a median tubercle on the female epistomal callus; and by the distinctive vestiture on pronotum and elytra.

Female: Length 2.8 mm, 2.7 times as long as wide; color dark brown, vestiture pale. Frons convex above, moderately impressed on lower half; epistomal callus rather poorly formed except for a distinct median tubercle, upper slope ornamented by a single rank of reddish brown setae. Pronotum 1.06 times as long as wide; armed on each anterolateral area by a sublongitudinal row of six crenulations; surface irregularly, longitudinally strigose through confluence, punctures obscure, not impressed;

vestiture of suberect, rather abundant, stout setae. Elytra 1.8 times as long as wide, 2.1 times as long as pronotum; basal margins each armed by a row of low crenulations; striae slightly impressed, punctures small, distinctly impressed, not confluent; interstriae about twice as wide as striae, almost smooth, shining, fine punctures numerous, confused. Declivity convex, steep; moderately impressed between left and right interstriae 3; striae 1 impressed, punctures mostly obsolete; granules not evident on interstriae; vestiture of rather abundant interstitial setae of two kinds, ground cover of white, shorter, moderately coarse (but weak) setae that extend to base, and erect rows of longer (one and one-third times), yellowish setae largely confined to declivity, each about as long as distance between rows; some erect setae extend irregularly to base.

Distribution: Bolivia to Argentina.

Argentina: Pasque Aconquija, Tucuman, 10-XII-1950, R. Gollbach.

Bolivia: Cochabamba (presumably from F. Woytkowski).

Notes: The above treatment was based on 1 female that I had compared to the Eggers series of this species at Washington and Wein.

Cnesinus vestitus Eggers

Cnesinus vestitus Eggers, 1933:16. Holotype ♀; Colonia Tovar, Venezuela; MNHN, Paris (References in Wood & Bright c1992:212)

Diagnosis: Distinguished by the presence of crenulations on the anterolateral areas of the pronotum; by the short, fine, hairlike, recumbent, elytral setae; and by the large, brightly colored epistomal setae in the female.

Male: Similar to female except epistomal callus reduced, its upper slope ornamented by a single rank of yellowish brown setae; setae cover almost entire pronotum; erect bristles on elytra greatly reduced in length and number.

Female: Length 3.3–3.7 mm, 2.9 times as long as wide; color dark reddish brown. Frons with eyes separated by 1.6 times width of an eye, upper half convex, smooth, impunctate, a few setae laterally at margin of eyes; lower half moderately impressed, epistomal callus smooth, shining, transversely about two-thirds as wide as lower frons, longitudinally very short, its upper slope ornamented by a very large brush of rather long, brightly colored reddish brown setae; lateral margins acute, ornamented by conspicuous, rather long, coarse setae. Pronotum 1.1 times as long as wide; posterolateral areas finely punctured, punctures lost through confluence on anterior half and on median half of posterior half, these areas finely, longitudinally strigose, ridges smooth, shining; fine, rather short setae of moderate abundance on all margins. Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; basal margins armed by low, weak crenulations, a row of weak submarginal crenulations indicated; striae narrowly, abruptly, moderately impressed, punctures small, very close, some confluent; interstriae about three times as wide as striae, surface smooth,

brightly shining, with fine, dense, confused punctures. Declivity convex, steep, moderately impressed between interstriae 3, striae 1–3 not clearly indicated except by darker color of cuticle, punctures small, confused with those of interstriae; vestiture of ground cover of abundant, recumbent, coarse hair to base and sparse rows of erect, slender bristles mostly on declivity, bristles on disc about as long as distance between rows, almost twice as long on declivity, bristles also present on interstriae 1.

Distribution: Venezuela: Colonia Tovar; Aragua; Merida, Merida, 22-IX-1969, 1700 m, Japanese bamboo, SLW.

Hosts: *Bambusa vulgaris*.

Biology: Boring into nodes of large stems.

Notes: The above treatment was based on 14 specimens. I compared 2 of my females directly to the holotype.

Cnesinus hispidulosus Wood, n. sp.

Cnesinus hispidulosus Wood: Holotype ♀; Itinga do Maranhao, Maranhao, Brazil; MZUSP, Sao Paulo, designated below

Diagnosis: Distinguished from *ampliatus* Schedl by the slightly larger size; by the sharply pointed, conical median tubercle on the female epistoma; and by the blunt, apically flattened erect setae on the declivity.

Female: Length 1.75 mm, 2.5 times as long as wide; color dark reddish brown, vestiture pale. Frons about as in *ampliatus* except median tubercle on epistoma conical, sharply pointed and impressed area shining on upper third, reticulate below. Pronotum 1.0 times as long as wide; anterolateral angles armed by a row of 4 or 5 asperities; surface rugose-punctate, mostly shining, punctures small, obscure, at base of setae; vestiture rather abundant, of semirecumbent, rather short, mostly blunt setae. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; striae weakly, abruptly impressed, punctures small, distinctly impressed, not confluent; interstriae slightly wider than striae, granular, punctures and tubercles obscurely evident. Declivity steep; weakly submarginate at apex of suture; interstriae 1–3 as wide as striae, tubercles obscurely evident. Vestiture of abundant stout ground scales, each about 6 times as long as wide, and erect rows of moderately stout, blunt, erect bristles, many of them with their apex slightly flattened, slightly shorter on lower third of declivity length.

Distribution: Brazil (Maranhao).

Type material: The female holotype was taken at Itinga do Maranhao, Maranhao, Brazil, VII-2002, ethanol trap in *Schizolobium amazonicum* stand, J.A. Ataide. The holotype is in the Museu de Zoologia, Universidade de Sao Paulo, Sao Paulo.

Cnesinus ampliatus Schedl

Cnesinus ampliatus Schedl, 1938:21. Lectotype ♀; Isla Martin Garcia, Buenos Aires, Argentina; NHMW, Wien, present designation (References in Wood & Bright c1992:205)

Male: Similar to female except epistomal tubercle and reddish brown setae absent.

Female: Length 2.0–2.2 mm, 2.6 times as long as wide; color dark reddish brown, vestiture pale. Frons moderately concave from epistoma to distinctly below upper level of eyes; median half between eyes smooth, shining, epistoma moderately elevated, its median one-fifth armed by a rather strong, blunt tubercle; row of reddish brown setae on upper margin of epistomal process rather dense. Pronotum 1.03 times as long as wide; anterolateral angles each armed by a row of about 6 asperities; disc rather coarsely granulate, finer on anterior fifth; vestiture of rather coarse, recumbent, long hair. Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; striae weakly, abruptly impressed, punctures rather large, at least partly confluent; interstriae slightly wider than striae, granular, punctures and tubercles not clearly evident. Declivity steep, shallowly impressed on interstriae 1 and 2; striae more distinctly impressed, punctures deeper than on disc; interstriae as wide as striae, rather weakly convex, each bearing a row of small, suberect tubercles on 3 and 4 and basal third of 1 and 2. Vestiture on disc of ground cover of abundant, recumbent, moderately coarse, rather long hair, less abundant to almost obsolete on declivity; and central rows of erect bristles mostly on declivity, most bristles equal in length to distance between rows, shorter on 1 and 2 below, their tips mostly pointed; on 1 specimen from Brazil erect setae extend to posterior third of disc.

Distribution: Argentina to Brazil.

Argentina: Isla Martin Garcia, Buenos Aires, I-1938, M.J. Viana.

Brazil: Nova Teutonia, Santa Catarina, 17-V-1949, F. Plaumann; Code 004, R.A. Beaver, presumably Mato Grosso.

Host: *Pouteria salicifolia* (Bright & Skidmore 2002:33).

Notes: The above treatment was based on the female syntype from Argentina that Schedl subsequently labeled as the “holotype,” and on 1 female from Brazil. Because a holotype can be designated only in the original publication of the species, Schedl’s (1979:19) designation of a “holotype” was invalid. I here designate that syntype (Schedl’s holotype) as the lectotype of *Cnesinus ampliatus* Schedl.

Cnesinus setosus Eggers

Cnesinus setosus Eggers, 1943:377. Holotype ♀; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:211)

Diagnosis: Distinguished from *advena* Schedl by the large size; by the reticulate upper frons; and by details of elytral sculpture as mentioned in the key above.

Female: Length 2.3 mm, 2.4 times as long as wide; elytra dark brown, pronotum very dark brown. Frons convex above, moderately, subconcealedly impressed on lower half, epistomal callus weakly developed, ornamented by a transverse row (2 ranks) of yellowish setae; surface of impressed and convex areas reticulate, largely

impunctate, a few short setae in lateral areas. Pronotum 0.95 times as long as wide; similar to *hispidus* Eggers except longitudinal rugae coarser and vestiture less abundant. Elytra 1.7 times as long as wide, 2.0 times as long as pronotum; striae distinctly impressed, punctures moderately large, distinct; interstriae slightly wider than striae, shining, each with a row of setiferous granules, numerous, confused small punctures at base of ground setae. Declivity convex, steep, weakly subsulcate on lower half; striae narrowly impressed on basal half, punctures minute to obsolete, some punctures present below on right elytron. Vestiture in ground cover rather coarse, recumbent, moderately abundant, half as long as erect bristles on disc, bristles longer on declivity, longest about equal to distance between rows on declivity.

Distribution: Bolivia: Cochabamba (presumably by F. Woytkowski).

Notes: The above treatment was based on the female holotype. A presumed male from San Antonio de Barra, Bahia, Brazil, is in the DEI Munchenberg Collection.

Cnesinus advena Schedl

Cnesinus advena Schedl, 1973:169. Holotype ♀; Utiariti, Rio Papagaio, Mato Grosso, Brazil, 325 m; MZUSP, Sao Paulo, Brazil (References in Wood & Bright c1992:205)

Diagnosis: Distinguished by the presence of a row of about 6 crenulations on anterolateral area of pronotum; by the distinctly impressed elytral striae; by the coarsely sculptured pronotum; and by other characters.

Male: Similar to female except epistomal callus and brush smaller, less well formed.

Female: Length 1.6–2.0 mm, 2.6 times as long as wide; color very dark brown. Frons about as in *vestitus* Eggers except epistomal callus less strongly elevated, brush of reddish brown setae less than half as large, lateral setae much finer, shorter, less abundant. Pronotum equal in length and width; anterolateral areas armed by a sublongitudinal row of about 6 crenulations; surface rather coarsely, longitudinally strigose, punctures not evident, ridges very narrow, anterior third minutely, longitudinally strigose; vestiture of rather abundant, stout, rather short, suberect setae. Elytra 1.7 times as long as wide, 1.9 times as long as pronotum; basal margins armed by a row of low crenulations; striae 1 moderately, others weakly impressed, punctures very close, distinct, moderately large; interstriae about twice as wide as striae, surface smooth, shining, with numerous, very fine, confused punctures, each interstriae with an obscure central row of small tubercles. Declivity convex, steep; striae 1 and 2 with punctures distinctly impressed, smaller than disc; interstriae 2 weakly impressed; vestiture moderately abundant, shorter, recumbent, rather stout interstitial ground setae and interstitial rows of erect bristles, each bristle rather stout, slightly shorter than distance between rows, within a row somewhat irregular, closer on declivity than on disc.

Distribution: Brazil to Paraguay.

Brazil: Utiariti, Rio Papagaio, Mato Grosso, 325 m.

Paraguay: Dept. San Pedro, Carumbe, I-1971, R. Golbach.

Notes: The above treatment was based on 1 male and 2 females that I compared to a female paratype at NHMW, Wien.

Cnesinus robai Blackman

Cnesinus robai Blackman, 1943:374. Holotype ♀; Santander Department, Colombia; USNM, Washington (References in Wood & Bright c1992:211)

Diagnosis: Distinguished from *lucaris* Wood and *cof-faeae* Schedl by the presence of a broad median tubercle or very short, transverse carina at level of ocular sinuation on female frons; anterolateral areas of pronotum armed by a sublongitudinal row of several crenulations.

Male: Similar to female except frontal carina absent, epistomal callus poorly formed, less strongly elevated, brush yellowish, of only one rank of setae, setiferous interstitial punctures tend to be granulate, granules on declivity larger.

Female: Length 1.9–2.4 mm, 2.7 times as long as wide; color brown, pronotum darker. Frons convex on upper half, central area glabrous to above upper level of eyes, a few short setae in lateral areas at margins of eyes; median line at level of ocular sinuation armed by a short, transverse carina (a tubercle in some specimens) well above epistomal elevation; epistomal callus smooth, shining, its upper margin on median third moderately elevated, reddish brown brush of setae on its upper slope thin, of 1 or 2 ranks, lateral setae on margins sparse. Pronotum 1.05 times as long as wide; surface on lateral thirds of posterior half moderately, rather deeply punctured, these punctures neither elongate nor confluent, median area rather coarsely, longitudinally strigose through confluence but punctures not evident, finer on anterior third; vestiture of 2 kinds of setae, fine short, hairlike and rather coarse, suberect, mostly twice as long as hair. Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; basal margins armed by low crenulations; striae slightly impressed, punctures moderately large, distinct, very close, some confluence toward declivity; interstriae one and one-half to twice as wide as striae, surface shining, minutely irregular, fine punctures obscure, somewhat confused on most interstriae. Declivity convex steep, weakly impressed between interstriae 3; punctures on striae 1 and 2 larger and deeper than on disc; interstriae 3–9 with a few fine granules; vestiture of very few short setae in ground cover, and interstitial rows of erect, stout bristles to base, bristles equal in length to distance between rows, spaced within a row by 1–3 lengths of a bristle.

Distribution: Colombia: El Bosque, Caicedonia, Valle del Cauca, VI-1958, tallo de cafe, J. Restrepo; Sevilla, Caicedonia, Valle del Cauca, VIII-1959, ex cafe, Betrem;

Chinchina, Caldas, 14-VI-1959, #12, ramas de café, M. Benavides; El Jardín, Antioquia, V-1958, en café, E. Giraldo.

Hosts: *Coffea arabica*.

Biology: Taken from pith tunnels in small branches.

Notes: The above treatment was based on 47 specimens, 1 female of which I compared directly to the holotype of *Cnesinus robai* Blackman.

Cnesinus lucaris Wood

Cnesinus lucaris Wood, 1974:5. Holotype ♂; Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:209)

Diagnosis: Distinguished from *robai* Blackman by the absence of a female frontal carina; by the more nearly carinate epistomal callus with the brush more extensive; and by the near absence of clear punctures on the posterolateral fourth of the pronotum.

Male: Similar to female except epistomal callus smaller, poorly formed, brush yellowish, with one rank of setae.

Female: Length 2.2–2.5 mm, 2.7 times as long as wide; color dark brown, elytra often reddish brown. Frons about as in *robai* except carina absent, callus transversely impressed, its upper margin sometimes appearing almost as a transverse carina in some specimens, brush of reddish brown setae on upper margin much more extensive (of 4 or more ranks). Pronotum 1.1 times as long as wide; surface similar to *robai* except most punctures on posterior half confluent, strigose area finer, not as deep. Elytra similar to *robai* except discal striae 1–3 confluent, setae in ground cover more numerous on disc and declivity, erect bristles much more slender and distinctly longer.

Distribution: Venezuela: Colonia Tovar, Aragua, 4-V-1970, 1700 m, No. 480, ex liana, SLW; Merida, Merida, 29-XII-1969, 1700 m, No. 210, ex liana, 22-IX-1969, No. 7 ex twig, No. 6 ex *Vismia* twig, 8-XI-1969, No. 119, ex *Rubus*, SLW.

Biology: Taken from pith tunnels in small stems.

Notes: The above treatment was based on the type series of 21 specimens and on 15 other specimens.

Cnesinus coffeae Schedl

Cnesinus coffeae Schedl, 1939:12. Holotype ♀; La Esperanza, Colombia; BMNH, London (References in Wood & Bright c1992:206)

Diagnosis: Distinguished from *lucaris* Wood by the finer, closer, deeper pronotal strigosity; by the more complete confluence of all strial punctures; by the much shorter elytral bristles; and by the longer epistomal brush of more brightly colored female setae.

Male: Similar to female except epistomal callus reduced in size, brush yellowish, less than half as extensive (2-ranked).

Female: Length 2.3–2.5 mm, 2.7 times as long as wide; color dark reddish brown. Frons as in *lucaris* except epistomal callus more strongly elevated, brush much more extensive and more strongly colored reddish

brown; lateral margins more acutely raised. Pronotum as in *lucaris* except more finely, closely, deeply strigose, all setae much more slender. Elytra about as in *lucaris* except striae slightly more strongly impressed, almost all punctures confluent, interstitial setae more slender, erect bristles shorter (about half as long as distance between rows on disc and declivital interstriae 1 and 2), almost as long as distance between rows on lateral areas of declivity.

Distribution: Colombia: La Esperanza; Bogota, 9-VI-1937, *Coffea arabica*, P. Roba.

Notes: The above treatment was based on 1 male and 1 female that I compared to the female holotype of *Cnesinus coffeae* Schedl and to Schedl's paratypes.

Cnesinus costulatus Blandford

Cnesinus costulatus Blandford, 1896:137. Lectotype ♀; Volcan de Chiriqui, Chiriqui, Panama; BMNH, London, designated by Wood 1982:234 (Synonymy and references in Wood & Bright c1992:207) *Cnesinus similis* Blackman, 1943:375. Holotype ♀; Panama; USNM, Washington

Diagnosis: Distinguished from *porcatus* Blandford by the smaller size; by the shining female frons above the transverse carina; and by the less-abundant declivital ground vestiture, with major setae more slender, longer; the bicarinate discal interstriae distinguish these 2 species from all others.

Male: Similar to female except carina absent, upper frons reticulate.

Female: Length 2.0–2.3 mm, 2.24 times as long as wide; color black. Frons transversely divided at level of ocular situation by an acute carina slightly longer than narrowest distance between eyes; upper area semicircular, smooth, shining, with a few minute punctures extending to upper level of eyes. Pronotum 0.93 times as long as wide; surface coarsely, longitudinally strigose, crests shining, grooves rather dull, confluent punctures not evident; vestiture of moderately abundant, fine, rather long hair. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; basal margins acutely elevated into a continuous costa; striae abruptly, rather deeply impressed, shining, rather large punctures mostly confluent but clearly indicated near base except on 1; interstriae as wide as striae, their margins narrowly elevated, shining, central half of each sulcate, dull, setiferous punctures very fine, obscure. Declivity steep, convex; interstriae narrower than on disc, with a single, central costa on upper third of each, costa broken into a row of subseriate granules below; vestiture of fine, erect hair in interstitial rows of closely set, erect setae, each about as long as distance between rows.

Distribution: Mexico (Oaxaca) to Colombia.

Colombia: 24 km E Barbosa, Antioquia, 18-VII-1970, 1200 m, No. 695, Lauraceae tree twigs, SLW.

Hosts: Lauraceae tree, 1 liana and 2 other unidentified tree species.

Biology: Taken from pith tunnels in small stems.

Notes: The above treatment was based on 24 Central American specimens and on 4 specimens from Colombia. I compared 1 of my females of *Cnesinus costulatus* Blandford directly to the lectotype.

Cnesinus porcatus Blandford

Plate IX

Cnesinus porcatus Blandford, 1896:137. Lectotype ♀; Volcan de Chiriqui, Panama; BMNH, London, designated by Wood 1982:236 (References in Wood & Bright c1992:210)

Diagnosis: Almost identical to *costulatus* Blandford except distinguished by the larger size; by the reticulate female frons above the carina; by the more abundant declivital ground vestiture; and by the stouter, shorter erect interstitial setae.

Male: Similar to female except frontal carina absent.

Female: Length 2.8–3.1 mm, 2.3 times as long as wide; color black. Frons above carina uniformly reticulate, with a few minute punctures; below carina broadly, concavely impressed, lateral margins partly acute. Pronotum and elytra about as in *costulatus*.

Distribution: Guatemala to Venezuela.

Venezuela: A Moritz specimen, presumably taken at or near his home at Colonia Tovar, Aragua.

Hosts: *Oreopanax capitatus*, *Quercus* sp., 2 other unidentified tree species, and 1 unidentified liana species.

Biology: Taken from pith tunnels in small stems.

Notes: The above treatment was based on 37 specimens from Central America. One female was compared by me directly to the lectotype.

Cnesinus squamosus Wood

Cnesinus squamosus Wood, 1968:102. Holotype ♀; Lower Rio Tempisque, Guanacaste, Costa Rica; USNM, Washington (References in Wood & Bright c1992:212)

Diagnosis: Clearly allied to *lucaris* Wood except pronotal row of asperities absent. Distinguished by the large, dense pronotal and elytral scales; by the emarginate and divaricate apex of the elytra; pronotal asperities absent.

Male: Similar to female except frontal carina and tufts of reddish brown setae absent.

Female: Length 1.7–2.1 mm, 2.5 times as long as wide; color brown. Frons with a crescent-shaped, transverse carina midway between level of antennal insertion and upper level of eyes (level of ocular situation), convex above carina, moderately impressed below; tufts of rather long, close, erect, reddish brown setae above epistoma and on lateral areas largely obscure surface; upper frons reticulate-granulate, with a few short, recumbent yellowish setae on marginal areas; eyes separated by 2.5 times width of an eye. Pronotum 1.0 times as long as wide; surface coarsely, closely, deeply punctured, puncture rim opposite from pronotum summit often slightly elevated; vestiture abundant, obscuring surface, of short scales each about 2 or 3 times as long as wide, and equally

short, slender bristles intermixed. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; apex of suture emarginate, tips of elytra moderately explanate; basal margins armed by a row of crenulations; striae impressed, punctures rather large, obscured by confluence; interstriae almost twice as wide as striae, surface apparently densely punctured (obscured by vestiture), each interstriae with a central row of granules. Declivity rather steep, convex, ending below in explanate extension; interstriae 1, 2, and 5 attaining apex, 1 moderately, 5 strongly elevated, 3, 4, 6, 7, and 8 convex and ending near middle; vestiture of dense, short, interstitial scales each as wide or wider than long, and erect rows of stout bristles, each about three times as long as scales, bristles about two-thirds as long as distance between rows, spaced within a row by similar distances.

Distribution: Costa Rica to Venezuela.

Venezuela: 3 km E Lagunillas, Merida, 12-I-1970, 1000 m, No. 336, liana, SLW.

Biology: Taken from pith tunnels in small stems.

Notes: The above treatment was based on the type series of 12 specimens and on 184 specimens from Venezuela.

Cnesinus denotatus Wood

Cnesinus denotatus Wood, 1968:107. Holotype ♀; Barro Colorado Island, Canal Zone, Panama; USNM, Washington (References in Wood & Bright c1992:207)

Diagnosis: Transverse female frontal carina at level of antennal insertion, female epistomal callus and reddish brown brush of setae absent (both present in male).

Male: Similar to female except frontal carina absent, a poorly formed callus present, with 1 row of setae on its upper slope; pronotal and elytral setae more abundant.

Female: Length 1.8–1.9 mm, 2.4 times as long as wide; color dark reddish brown. Frons strongly impressed at level of ocular situation, convex above, flattened below, a strongly elevated, transverse carina on median fourth at level of antennal insertion, carina almost as wide as high; surface minutely reticulate-granulate; vestiture sparse, short, largely confined to lateral areas. Pronotum 1.07 times as long as wide; surface shining, punctures rather fine, coarse, close, separate in posterolateral areas, 2 or more longitudinally confluent elsewhere; fine, hair-like ground setae and short, stout setae restricted to marginal areas. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; basal margins armed by row of moderately coarse crenulations; striae weakly impressed, punctures rather large, distinct; interstriae about twice as wide as striae, shining, punctures fine, abundant, confluent. Declivity broadly convex, steep, feebly impressed between interstriae 3; striae 1–3 with punctures distinct; vestiture of moderately abundant, short ground setae, slender to base on disc, stout on declivity (each 2–4 times as long as wide), and rows of erect, stout bristles, each bristle about as long as distance between rows,

spaced within a row by similar distance, slightly shorter and closer on declivity.

Distribution: Costa Rica to Venezuela.

Venezuela: 9 km S Barrancas, Barinas, 5-XI-1969, 150 m, No. 118, *Serjania*, SLW.

Hosts: *Oreopanax capitata*, *Serjania* sp.

Biology: Taken from pith tunnels in small stems.

Notes: The above treatment was based on the holotype and allotype and on 1 female from Venezuela.

Cnesinus adustus Schedl

Cnesinus adustus Schedl, 1948:266. Syntypes ♀; Costa Rica: Turrialba; NHMW, Wien (Synonymy and references in Wood & Bright c1992:205)

Cnesinus atrodeclivis Wood, 1968:108. Holotype ♀; Zamorano, Morazan, Honduras; USNM, Washington

Diagnosis: Frons very modestly impressed, carina very short (on median one-fifth), low, located below middle but distinctly above level of antennal insertion; declivity usually dark (both cuticle and setae).

Male: Similar to female except epistomal callus more poorly formed, setae on its upper slope form a single row.

Female: Length 2.0–2.4 mm, 2.5 times as long as wide; dark reddish brown, both cuticle and setae much darker on declivity. Frons shallowly impressed at level of antennal insertion, somewhat flattened to upper level of eyes, armed at level of ocular sinuation by a small, low, transverse, crescent-shaped carina on median one-sixth; epistomal callus weakly formed, reddish brown brush of setae on its upper slope about 2-ranked; setae on lateral thirds above carina long, fine, conspicuous. Pronotum 1.06 times as long as wide; similar to *denotatus* except all areas with punctures, more coarsely confluent. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; about as in *denotatus* except striae punctures mostly confluent near declivity, declivital striae more distinctly impressed, ground setae on disc and declivity similar; rather slender, erect bristles inconspicuous, each about half to two-thirds as long as distance between rows.

Distribution: Honduras to Colombia (?).

Colombia: Unconfirmed oral report.

Hosts: *Valeria scandens*.

Biology: Taken from pith tunnels in small stems.

Notes: The above treatment was based on the seven specimens in the type series of the synonym, *atrodeclivis*, and on syntypes of *adustus*. The report from Colombia was probably based on an error in identification.

Cnesinus ocellaris Blandford

Cnesinus ocellaris Blandford, 1896:140. Holotype, sex?; [Colonia Tovar?], Venezuela; BMNH, London (References in Wood & Bright c1992:210)

Diagnosis: Eyes greatly enlarged, coarsely faceted, separated above by less than one-half width of an eye; transverse female carina two-thirds as long as distance between eyes.

Female: Length 2.4 mm, 2.7 times as long as wide; color dark reddish brown. Frons shallowly impressed below, eyes separated above by distance equal to one-half width of an eye; epistomal callus poorly developed, almost obsolete, brush of reddish brown setae on its upper slope large, broad, at least 4-ranked; transverse carina at level of ocular sinuation, moderately large, its transverse length equal to two-thirds distance between eyes; surface above carina minutely, transversely etched, shining, impunctate; a few setae in lateral areas. Pronotum 1.05 times as long as wide; surface shining, resembling *adustus* Schedl but much more coarsely, longitudinally strigose; vestiture confined to marginal areas, of fine, short, hairlike ground setae and, on anterior fourth, longer, stout setae. Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; crenulations on basal margins indicated, weak; striae weakly impressed, punctures distinct; interstriae twice as wide as striae; about as in *denotatus* except declivity distinctly impressed between interstriae 3, and erect bristles distinctly shorter.

Distribution: Honduras to Venezuela.

Venezuela: A Moritz specimen, presumably taken near his home at Colonia Tovar, Aragua.

Hosts: *Serjania* sp.

Biology: Taken from a pith tunnel in a small stem.

Notes: The above treatment was based on 1 female from Honduras. The type was seen but was not compared directly to the Honduras specimen.

Cnesinus adusticus Wood

Cnesinus adusticus Wood, 1967:87. Holotype ♀; Los Almendros, Paraiso, Honduras; USNM, Washington (References in Wood & Bright c1992:205)

Diagnosis: Similar to *ocellaris* Blandford but pronotal sculpture and elytral vestiture very different, as described below.

Male: Similar to female except frontal carina absent, epistomal callus poorly formed, its brush of one rank of setae.

Female: Length 2.7–3.0 mm, 2.4 times as long as wide; color dark reddish brown, elytral vestiture pale with a dark, transverse band at base of declivity (obscure in series from Colombia). Frons similar to *ocellaris* except eyes more finely faceted, separated above by slightly more than width of an eye, vestiture on lateral areas above carina much more abundant, longer, conspicuous. Pronotum 1.05 times as long as wide; posterolateral areas with fine punctures, about half of them longitudinally confluent with at least one other puncture, other areas entirely confluent, much finer than in *ocellaris*. Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; row of crenulations at base poorly formed; striae moderately impressed, punctures near declivity mostly confluent; interstriae twice as wide as striae, shining, fine punctures confused. Declivity steep, convex, modestly impressed between interstriae 3; vestiture with ground cover slender at base of disc, stouter

near declivity, almost scalelike on declivity (each 4–6 times as long as wide), erect bristles geographically variable, short, broad, about twice as long as ground cover in Honduras specimens, ground setae and bristles much more slender and longer in specimens from Colombia and Mexico.

Distribution: Mexico (Veracruz) to Colombia.

Colombia: El Bosque, Caicedonia, Valle del Cauca, 30-VI-1959, ramas de café, J. Restrepo; La Cuchillo, Sevilla, 19-VI-1959, guamo seco, J. Restrepo.

Hosts: *Acacia pennatula*, *Coffea arabica*, *Phoradendron* sp.

Biology: Taken from pith tunnels in small stems.

Notes: The above treatment was based on the type series of 32 specimens from Honduras, 1 specimen from Mexico, and 12 specimens from Colombia.

GENUS *PAGIOCERUS* EICHHOFF

Pagiocerus Eichhoff, 1868:148. Type-species: *Pagiocerus rimosus* Eichhoff = *Bostrichus frontalis* Fabricius, subsequent designation by Hopkins 1914:126 (References in Wood & Bright c1992:213)

Diagnosis: Lateral margins of pronotum rounded; sutures of antennal club procurved; rostrum width at tip equal to distance between eyes.

Description: Length 1.9–3.5 mm, body rather stout; color reddish brown. Frons sexually dimorphic, variously impressed below, shallowly impressed to convex above; eyes rather widely separated above, sinuate on mesal margin; antennal funicle 7-segmented; 2 sutures procurved. Pronotum unarmed, punctured. Elytra with basal margins weakly crenulate; striae distinct, sculpture simple; declivity convex, steep; vestiture hairlike.

Distribution: Five species are known, 4 of them only from southern Brazil. The fifth species (*frontalis* Fabricius) occurs naturally from the southeastern USA to Argentina and has been transported through commerce in corn (=maize) seed to various other parts of the world.

Biology: The known species are monogynous and breed in large seeds of various trees and *frontalis*, in the Andean region, may infest maize seed both in the field and in storage.

Key to the Species of *Pagiocerus*

- 1. Frons at upper level of eyes convex, granular or smooth, shining, with a few very small punctures; pronotum substrigose, at least half of punctures confluent, crests between punctures mostly convex, smooth; declivital interstriae 2 usually constricted, often less than half as wide as a striae puncture, punctures minute to apex; median epistomal tubercle less laterally compressed (elevated crest dorsad from summit obsolete, crest orad from summit absent or conspicuous) a line drawn between summits of highest points on lateral margin passing entirely dorsad of base of median tubercle 2
- Frons at upper level of eyes weakly impressed, closely granulate-punctate; pronotum with surface either smooth or longitudinally etched, punctures smaller, not as deep, few confluent; interstitial punctures on disc fine, more numerous, strongly confused; declivital interstriae 2 as wide as striae 3
- 2(1). Frons much more strongly impressed above, almost to upper level of eyes, area above eyes convex, granular; epistomal tubercle without a ventral crest; pronotum rather finely, closely strigose, punctures small, rather shallow, mostly about twice as long as wide; interstriae smoother, punctures smaller, confused, setae mostly confused on disc and (slightly) declivity, each seta longer, finer, almost as long as distance between rows; Brazil; 2.7 mm *luederwaldti* Eggers
- Frons less strongly impressed above, area above eyes smoother, shining; epistomal tubercle with a slight ventral crest; pronotum less conspicuously strigose, punctures rather coarse, deep, close, most little longer than wide; interstriae more irregular (somewhat wrinkled), punctures and setae mostly uniseriate on disc, definitely uniseriate on declivity, setae shorter and stouter, length equal to less than two-thirds distance between rows; S USA to Argentina; 1.9–2.6 mm *frontalis* (Fabricius)
- 3(1). Surface of pronotum between punctures minutely etched; interstitial punctures on disc with punctures small, numerous, confused; declivital interstriae 1–3 all continue to apex, each as wide as an interstriae and armed by a uniseriate row of fine tubercles, punctures mostly obsolete; acutely elevated lateral margin of frons extending almost to level of ocular emargination, without a subdentate highest point; Brazil; 3.2 mm *cribricollis* Eichhoff
- Surface of pronotum between punctures smooth, shining; interstriae on disc with punctures small to irregular, less numerous, mostly in uniseriate rows; declivital interstriae 1 and 3 all continue

- to apex, each with a uniseriate row of punctures, tubercles absent; median epistomal tubercle more strongly, laterally compressed or not 4
- 4(3). Epistomal tubercle laterally compressed, crest extending dorsad from its summit present, line drawn between highest point on lateral summits touching or crossing this median crest; lateral margins of lower frons moderately, acutely elevated on its middle one-third; interstitial setae (apparently?) longer; Brazil (Goyas); 2.4–2.5 mm *eggersi* Wood
- Epistomal tubercle conical, not compressed, dorsal crest absent; lateral margins of lower frons weakly, uniformly elevated; interstitial setae uniseriate, of minute, slender hair on basal half of disc, stouter on declivity, on declivity each about 6 times as long as wide, one-third as long as distance between rows; Brazil (Mato Grosso); 2.0 mm *punctatus* Eggers

Pagiocerus luederwaldti Eggers

Pagiocerus luederwaldti Eggers, 1928:93. Holotype ♂; Sao Paulo, Parana, Brasil; Museu de Zoologia, Universidade de Sao Paulo (References in Wood & Bright c1992:214)

Pagiocerus major Schedl, 1976:64. Holotype ♀?; Brazil; NHMW, Wien (References in Wood & Bright c1992:214). *New synonymy*

Diagnosis: Distinguished from *frontalis* (Fabricius) by the smaller size; by the much more finely, closely strigose pronotum; by the more deeply impressed upper frons; and by the conical epistomal tubercle.

Male: Similar to female in all visible respects (specimens at hand in very poor condition).

Female: Length 2.6 (male)–2.7 (female) mm, 2.2 times as long as wide; color dark reddish brown. Frons strongly impressed on lower nine-tenths of area below upper level of eyes, deepest on its upper half; epistomal spine high, pointed, conical, without a ventral crest extending toward epistomal margin; concave area smooth, shining on lower half, somewhat granular above; area above concavity convex, rather finely rugose; a few minute, hairlike setae uniformly distributed. Pronotum 1.0 times as long as wide; surface finely, closely strigose, crests smooth, shining, convex; punctures small, moderately convex, about half of them confluent, distinctly larger near base; vestiture of fine, sparse, short hair near anterior and lateral margins. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae 1 moderately, others distinctly impressed, punctures large, distinct, almost confluent (especially on 1); interstriae about twice as wide as striae, smooth, shining, punctures very small, confused. Declivity broadly convex, steep; striae weakly impressed, narrower than on disc; interstriae 2 on left side half as wide as on right (right side as wide as striae 2 or 3); interstitial punctures uniseriate on 1. Vestiture of fine, short hair on disc, longer and somewhat coarser on and near declivity; interstitial setae confused (modestly on declivity), on declivity each seta almost as long as distance between rows.

Distribution: Brazil: “Alte sammlung, Brasilien.”

Notes: The above treatment was based on the male holotype of *luederwaldti* that is crushed, with the right elytron missing and most of the declivity is covered by glue, and the holotype of *major* Schedl (a female?). The

“Linhares” data published by Schedl (type of *major*) also came from a “paratype” of *major* that was actually a misidentified specimen of *cribricollis*.

Pagiocerus frontalis (Fabricius)

Plate X

Pagiocerus frontalis (Fabricius), 1801:389. Syntypes, sex?; Carolina; UZMC, Copenhagen (Synonymy and references in Wood & Bright c1992:213–214)

Pagiocerus rimosus Eichhoff, 1868:148. Syntypes, sex?; Hamburg Museum, lost

Bothrosternus hubbardi Schwarz, 1886:54. Holotype, sex?; St. Lucie, Florida, USA; USNM, Washington

Hylastinus fiorii Eggers, 1908:215. Holotype, sex?; Genua (Italia); Andr. Fiori Collection, Bologna

Pagiocerus chiriouensis Eggers, 1928:92. Holotype sex?; Panama: Volcan Chiriqui; NHMW, Wien

Pagiocerus zae Eggers, 1928:92. Lectotype, sex?; South American corn kernels; USNM, Washington, designated by Anderson & Anderson 1971:36

Pagiocerus nitidus Eggers, 1930:170. Holotype, sex?; Venezuela (Caracas); MNB, Berlin

Pagiocerus carabicus Eggers, 1940:136. Holotype, sex?; Trois Rivieres, Guadeloupe; NHMW, Wien

Diagnosis: Distinguished by the size; by the upper frons between upper level of eyes convex, smooth, with sparse, fine punctures; and by the distinctive sculpture of the declivity.

Male: Similar to female except frontal excavation deeper, extending almost to upper level of eyes.

Female: Length 1.9–2.6 mm, 1.9 times as long as wide; color dark reddish brown. Frons moderately impressed from just above epistoma to ocular situation; lateral margins below acute, a large, pointed median tubercle just above epistoma; almost glabrous except sparse setae on epistomal area; area above eyes rather coarsely punctured. Pronotum 1.0 times as long as wide; surface shining, closely, deeply, rather coarsely punctured, punctures longitudinally elongate, many confluent; glabrous. Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; basal margins not elevated, subcostate; striae feebly impressed, punctures moderately large, most subconfluent; interstriae about one and one-half times as wide as striae, shining, punctures small, indistinct, mostly uniseriate. Declivity convex, steep; sculpture about as

on disc except striae and punctures more distinctly impressed; some minute strial setae sometimes present, interstitial setae in uniseriate rows of short, almost hair-like, erect bristles (no ground setae), each bristle equal in length to about half distance between rows, spaced within a row by less than length of a bristle. Setae often absent, apparently due to abrasion.

Distribution: USA (North Carolina) to Argentina; occasionally intercepted worldwide in maize seed (exported from western South America).

Argentina: Cited in Wood & Bright c1992:213.

Bolivia: Cited in Wood & Bright c1992:213.

Brazil: Rio Salimoes, 1-X-1982, J. Adis.

Chile: Valle Lluta, Arica, Prov. Tarapaca, XI-1966, J. Jimenez.

Colombia: Fresno, Tolima, XII-1939, 1490 m, X-509, C. Carmona B.; Palmira, 23-VII-1958, C. Bravo; Pasto, Narino, 3-VII-1957, maize, A. Uniparro.

Ecuador: Cited in Wood & Bright c1992:213.

Peru: Monson Cave, Tingo Maria, 15-XII-1954, E.I. Schlinger, E.S. Ross.

Venezuela: Caracas; Venicia, Antioquia, 23-XI-1955, C.

Hosts: *Ocotea* spp., *Persea americana*, *P.* spp., *Zea mays*.

Biology: Breed in large seeds of the hosts, including stored maize.

Notes: The above treatment was based on my examination of several hundred specimens, including those at the USNM, Washington, NHMW, Wien, IRSNB, Brussels; the types of all synonyms except *rimosus* Eichhoff were examined. Several specimens determined by Eichhoff were also seen.

Pagiocerus eggersi Wood, n. sp.

Pagiocerus eggersi Wood: Holotype ♀; Jatahy, Goyas, Brazil; DEI, Muncheberg, designated below

Diagnosis: Distinguished by characters of the frons, pronotum, and elytra as summarized in the above key to species.

Male: Length 2.4–2.5 mm, 2.0 times as long as wide; color dark reddish brown.

Frons strongly concave from epistoma to upper level of eyes; area above eyes shining, rather coarsely, closely punctured, upper half of area between eyes obscurely subreticulate, shining, sparsely, minutely punctured, lower area more nearly smooth; lateral margin moderately, acutely elevated on its middle third, highest point at level of antennal insertion subdentate, lateral crest ending midway between epistomal margin and upper level of eye; epistoma armed by a large, laterally compressed, acute spine, with distinct crests extending dorsad and orad from its summit, a line drawn between subdentate summits on lateral margins touches or crosses this dorsal crest; setae small, sparse, hairlike on lower half, several stiff bristles at lateral margin near upper level of eye. Pronotum 0.95 times as long as wide; surface smooth,

shining, punctures oval (rarely more than twice as long as wide), rarely confluent on lateral fourths, largest in lateral areas near base, smaller mesad and cephalad, moderately deep; glabrous except sparse, fine hair on anterior fourth. Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; basal margins about as in *frontalis*; striae distinctly impressed, punctures rather large, mostly confluent, obscure; interstriae slightly wider than striae, smooth, shining, punctures rather small, almost uniseriate, no granules. Declivity broadly convex, steep; interstriae 1 and 2 on left side narrower than striae (wider on right side), punctures uniseriate, no tubercles. Vestiture mostly abraded, apparently slightly shorter than in *frontalis*.

Female: Similar to male except frontal concavity ending distinctly below upper level of eyes, apparently not as deep, bristles on margin near eye finer, shorter.

Distribution: Brazil (Goyas).

Type material: The female holotype and male allotype were taken at Jatahy, Goyas, Brazil, XI-1897. The holotype and allotype are in the DEI, Muncheberg.

Pagiocerus cribricollis Eichhoff

Pagiocerus cribricollis Eichhoff, 1868:148 (Syntypes 2 ♂; Brasilia; IRSNB, Brussels (References in Wood & Bright c1992:213)

Diagnosis: Distinguished from *frontalis* (Fabricius) by the larger size; by the slightly impressed, closely granulate-punctate upper frons at the upper level of the eyes; by the small, strongly confused interstitial punctures on the disc; and by the presence of minute tubercles on declivital interstriae 2.

Male: Length 3.2 mm, 2.0 times as long as wide; color dark reddish brown. Frons essentially as in *frontalis* except lateral elevation on lower half continued higher, close to level of emargination of eye; area above upper level of eyes to vertex distinctly impressed, closely, rather coarsely granulate-punctate. Pronotum 0.96 times as long as wide; surface shining, areas between punctures minutely etched longitudinally, punctures oval, rather shallow, close, few confluent; glabrous. Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; striae rather weakly impressed, punctures impressed, distinct; interstriae smooth, shining, moderately convex, about twice as wide as striae, punctures small, numerous, confused. Declivity rather broadly convex, steep; similar to *frontalis* except interstriae 1–3 all continue to apex, each as wide as a striae and armed by a uniseriate row of very fine tubercles. Vestiture of stout, erect setae, apparently confused on disc (abraded), in uniseriate rows on declivity, each about equal in length to half distance between rows.

Distribution: Brazil: “Bresil”; Linhares, E. Santo, IX-1972, Roppa & Alvarenga.

Notes: The above treatment was based on the male syntypes. A “paratype” of *major* Schedl (= *Pagiocerus luederwaldti* Eggers) at NHMW, Wien, is actually of this species. All 3 specimens are from Brazil.

Pagiocerus punctatus Eggers

Pagiocerus punctatus Eggers, 1928:93. Holotype ♂; Corumba, Mato Grosso, Brazil; NHMW, Wien (References in Wood & Bright c1992:214)

Diagnosis: Distinguished from *cribricollis* Eichhoff by the conical epistomal spine; by the much more weakly elevated lateral margins of the lower frons; and by the shorter interstitial setae, those setae on basal half of disc are of very fine, short hair.

Male: Length 2.0 mm, about 2.1 times as long as wide (elytra spread); color dark reddish brown. Frons rather strongly impressed from epistoma to upper level of eyes; epistomal tubercle rather strong, conical; lateral margins weakly elevated; surfaces shining below, apparently finely punctured above; vestiture largely abraded, sparse; vertex closely, finely punctured. Pronotum 0.93 times as long as wide; surface smooth, shining, punctures oval, distinctly impressed, those near center smaller, spaced by 1–3 diameters of a puncture, somewhat larger laterally, much larger near base (largest with reticulate centers); a few minute, hairlike setae near anterior margin. Elytra about 1.2 times as long as wide, about 1.4 times as long as pronotum; striae distinctly impressed, punctures coarse, close, distinct; interstriae slightly wider than striae, shining, somewhat wrinkled, punctures fine, some marked by short, transverse lines, uniseriate. Declivity broadly convex; steep; interstriae narrower than on disc, half as wide as striae, obscurely convex, with fine, uniseriate punctures. Vestiture uniseriate, of fine, minute interstitial hair on anterior half of disc, coarser on and near declivity (each seta at least 8 times as long as wide), each less than half as long as distance between rows.

Distribution: Brazil: Corumba, Mato Grosso.

Notes: The above treatment was based on the male holotype.

GENUS *EUPAGIOCERUS* BLANDFORD

Eupagiocerus Blandford, 1896:133. Type-species: *Eupagiocerus dentipes* Blandford, monobasic (References in Wood & Bright c1992:214)

Diagnosis: Lateral margins of pronotum subacutely elevated, costate; sutures of antennal club strongly procurved.

Description: Length 2.1–3.8 mm, 1.8–2.3 times as long as wide. Frons convex above, flattened to shallowly concave below; frons sexually dimorphic; eyes widely separated, mesal margins sinuate; antennal funicle 7-segmented, club rather slender, with 2 procurved sutures on basal half. Pronotum with lateral margins costate; unarmed, punctured. Elytra with bases marked either by a continuous costa or by a weak row of feebly elevated crenulations; striae impressed, punctures impressed or obsolete; interstriae variable; declivity steep, convex, only the 1 endemic species is armed by moderately large tubercles.

Distribution: Three species are known from Guatemala to Venezuela and Peru. Only 1 has been reported from South America.

Biology: All 3 of the known species are monogynous and bore pith tunnels in stems 1–8 cm in diameter where the larvae of 2 of them feed directly on host tissue. The South American species, *ater* Eggers excavates similar parental pith tunnels but differs by the cultivation of an ambrosial fungus on the walls of those tunnels on which both larvae and adults feed.

Notes: A key to the species of *Eupagiocerus* is in Wood (1982:249–250).

Eupagiocerus ater Eggers

Eupagiocerus ater Eggers, 1931:14. Holotype ♂; Caracas, Venezuela; MNB, Berlin (Synonymy and references in Wood & Bright c1992:214)

Eupagiocerus nevermanni Schedl, 1952:350. Holotype ♀; Turrialba, Costa Rica; NHMW, Wien

Eupagiocerus serratus Wood, 1961:104. Holotype ♂; Paraiso, Canal Zone, Panama; USNM, Washington

Diagnosis: Declivital interstriae 1, 3–9 armed by pointed spines; mycetophagous.

Male: Similar to female except frontal carina absent and replaced by an impression and declivital sculpture finer.

Female: Length 2.1–2.6 mm, 2.0 times as long as wide; color dark brown to black. Frons above level of antennal bases convex, smooth, brightly polished in central area, reticulate at sides and above; epistomal margin weakly elevated, a flattened, rugose-reticulate, sparsely punctured area immediately above; antennal bases connected by a moderately elevated, procurved carina, subvertical on its lower (orad) side, moderately sloping, punctured, pubescent on its upper slope; vestiture rather abundant, longer and finer below, coarse, short above carina. Pronotum 0.9 times as long as wide; surface subshining, with minute, obscure longitudinal lines, becoming reticulate laterally and basally, punctures elongate, rather coarse, close, shallow; glabrous. Anterior half of propleuron impressed and ornamented by dense, yellow setae. Elytra 1.1 times as long as wide; basal margins acutely elevated on a continuous costa; striae impressed, punctures obsolete; interstriae one and one-half times as wide as striae, flattened basally, strongly convex and shining toward declivity (almost as high as wide), interstriae reticulate toward declivity (less regular on basal third), punctures small, confused, sparse on posterior half. Declivity steep, flattened, reticulate-granulate over both punctures and serrations; interstriae 1 vertically, strongly elevated, declining in height to lower third, armed by almost 10 serrations, 2 with small serrations at base, weakly elevated below, 3–9 each bearing two to four coarse serrations; vestiture confined to declivity, sparse.

Distribution: Costa Rica to Venezuela and Peru.

Colombia: 24 km E Barbosa, Antioquia, 18-VII-1970, 1200 m, No. 698, Lauraceae sp., SLW.

Peru: Exact locality not given on labels.

Venezuela: Caracas, by Moritz.

Hosts: *Serjania* spp., and other woody lianas.

Biology: Specimens were removed from biramous pith tunnels in stems 0.5–2.0 cm in diameter. Walls of the parental tunnels were covered by the fluffy, white mycelium of an ambrosial fungus on which adults and larvae fed. This mycelium apparently did not turn black with age as in other mycetophagous species.

Notes: The above treatment was based on 52 Central American specimens, on 1 from Peru, on 1 from Colombia, and on the holotype from Venezuela. The holotype, from Caracas, in all probability came from Colonia Tovar, Aragua, Venezuela, near the Moritz home. I compared 1 male directly to the holotype of *Eupagiocerus ater* Eggers.

GENUS *BOTHROSTERNUS* EICHHOFF

Bothrosternus Eichhoff, 1868:150. Type-species: *Bothrosternus truncatus* Eichhoff, monobasic (References in Wood & Bright c1992: 215)

Diagnosis: Sutures of antennal club straight; lateral margins of pronotum subacutely costate; prothoracic intercoxal piece transversely costate; female propleural

area excavated and conspicuously pubescent; some species at least partly mycetophagous; partly with males dwarfed and rare to xylomycetophagous.

Description: Length 1.9–3.1 mm, 1.9–2.2 times as long as wide; color dark brown to black. Frons convex above, flattened below, some species carinate; eyes widely separated, sinuate on anterior margins; antennal funicle 7-segmented; club slender, with 2 straight sutures. Pronotum unarmed, surface substrigose. Elytra with basal margins weakly subcrenulate; striae impressed, punctures obscure; interstriae simple, unarmed, partly subcarinate in some species; declivity convex, steep; vestiture hairlike.

Distribution: Wood & Bright (c1992:215) report 12 species from Mexico (Veracruz) to Argentina.

Biology: The species are monogynous. Parental axial pith tunnels are bored into small stems 0.5–5.0 cm in diameter. At least half of the species cultivate an ambrosial fungus on the walls of their tunnels on which larvae and adults feed. The mycelium is white and fluffy and does not darken with age as in other ambrosia beetles. At least some of the species appeared to feed directly on host tissue; in others there appeared to be a transitional habit of feeding initially on host tissue then later on the fungus mycelium.

Key to the Species of *Bothrosternus*

- 1. Elytral surface on discal interstriae smooth, shining, without any reticulation; Brazil; female 2.3–2.4 mm, male 2.3 mm *lucidus* Wood
- Discal interstriae minutely reticulate 2
- 2(1). Smaller species; elytral disc without interstitial setae, declivity steeper; more broadly convex, with ground cover confused, at least some setae scalelike 3
- Larger species; elytral declivity less steep, more strongly convex; all setae on elytra hairlike 4
- 3(2). Punctures near base of pronotum larger, very shallow, obscure; all interstitial setae on declivital interstriae 1–4 scalelike, most almost as wide as long; lower declivity more broadly convex; Venezuela; *Serjania*; 1.8–2.0 mm *affinis* Eggers
- Punctures near base of pronotum smaller, more distinct; most interstitial setae on declivital interstriae 1–4 stout, elongate (each more than eight times as long as wide), sparse, very short ground setae almost scalelike, pointed, some about three times as long as wide; lower declivity more narrowly convex; Brazil (Santa Catarina); 1.7–1.9 mm *artestrigosus* Schedl
- 4(2). Vestiture absent on elytral disc; declivital setae distinctly shorter than distance between rows; strial punctures very small to obsolete 5
- Interstitial setae on disc mostly uniseriate, about as long as distance between rows; striae on disc narrowly, abruptly, rather shallowly impressed, punctures obscure to obsolete 6
- 5(4). Interstitial setae on declivity slender, equal in length to half to two-thirds distance between rows; punctures on pronotum disc rather coarse, deep, several of them confluent, median line subacute; strial punctures on disc obsolete, on declivity minute, obscure; striae on disc abruptly, deeply impressed, as wide as striae on disc, less than half as wide on declivity; Brazil; 2.3 mm *rudis* Wood

- Interstitial setae on declivity very minute, about twice as long as diameter of an interstitial puncture; striae feebly impressed, punctures very small, distinctly impressed; interstriae on disc at least five times as wide as striae, punctures very small, distinctly impressed, confused *subopacus* Schedl
- 6(4). Interstitial setae on disc and declivity rather abundant to base, consisting of more abundant, short, fine, confused ground setae and indefinite rows of longer hair; pronotum also closely pubescent; female frons with a subacute, transverse carina at level of antennal insertion, a row of setae on its upper slope; Venezuela; *Serjania*, *Tabebuia*; female 2.3–2.4 mm, male 2.3–2.4 mm *hirsutus* Wood
- Interstitial setae much less numerous, almost all in rows with, little or no ground cover; female epistoma with a callus or male with a weak transverse carina 7
- 7(6). Female frons with a transverse carina at level of antennal insertion (as in *hirsutus*); erect interstitial setae on disc slender, pointed; punctures on pronotum averaging larger, closer; color very dark reddish brown; Colombia to Brazil; Lauraceae sp.; female 2.4–2.6 mm, male 2.5 mm *brevis* Eggers
- Female frons without a carina; erect interstitial setae on disc blunt, those near suture distinctly flattened; punctures on pronotum averaging smaller, more isolated; color medium reddish brown; Venezuela; *Serjania* sp.; female 2.1–2.3 mm, male 1.8–1.9 mm *truncatus* Eichhoff

Bothrosternus lucidus Wood

Bostrichus lucidus Wood, 1974:6. Holotype ♂; 260 km N Xavantina, Mato Grosso, Brazil, 12°49'S, 50°46'W (References in Wood & Bright c1992:215)

Diagnosis: Surfaces of most of pronotum and elytra smooth, shining (almost no reticulation).

Male: Similar to female except slightly smaller; frontal vestiture less abundant; interstitial tubercles on declivity smaller, poorly formed.

Female: Length 2.3–2.4 mm (male 2.3 mm), 2.2 times as long as wide; color reddish brown. Frons modestly, transversely impressed from epistomal margin to level of antennal insertion, broadly convex above; convex area reticulate; punctures small, obscure, on lower and lateral areas; vestiture of fine, erect, moderately long hair on impressed and lateral areas to upper level of eyes. Pronotum 0.97 times as long as wide; surface mostly smooth, shining, obscure areas of reticulation on some specimens, punctures small, shallow, oval, separated by 1–4 diameters of a puncture; glabrous. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; basal margins conspicuously elevated and continuously costate, crenulations not indicated; striae rather weakly impressed, punctures moderately large, at least slightly confluent; interstriae about twice as wide as striae, surface almost smooth, shining, punctures minute, mostly uniseriate. Declivity convex, rather steep; striae punctures more deeply impressed, interstriae as wide as striae, 1–9 each armed by a row of small, rounded tubercles; vestiture confined to declivity, consisting of uniseriate rows of rather slender, blunt, erect bristles (no ground setae) each almost as long as distance between rows,

spaced within a row by half to full length of a bristle; disc glabrous.

Distribution: Brazil: 260 km N Xavantina, Mato Grosso.

Biology: Presumably removed from small branches; 5 of 15 specimens were male.

Notes: The above treatment was based on the type series of 15 specimens.

Bothrosternus affinis Eggers

Bothrosternus affinis Eggers, 1933:14. Holotype ♂; San Esteban, Venezuela; MNHN, Paris (References in Wood & Bright c1992:215)

Diagnosis: This is the only known species in this genus with the declivital interstriae clothed by numerous, short, broad scales.

Male: Length 1.8–2.0 mm, 2.2 times as long as wide; color very dark brown, scales pale. Frons similar to male *lucidus* Wood except impression extending to level of ocular sinuation; surface reticulate; vestiture rather sparse, largely confined to lateral margins. Pronotum 1.0 times as long as wide; surface minutely (longitudinally) reticulate, rather dull; punctures coarse, very shallow on basal fourth, most separated by one-fourth diameter of a puncture, on middle third punctures smaller, half as large as those at base, each twice as long as wide, several confluent, smaller toward anterior margin; glabrous. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; basal margins weakly elevated, with an obscure row of very small crenulations; striae weakly, abruptly impressed, punctures rather small, confluent; interstriae almost three times as wide as striae, surface obscurely reticulate (80X), punctures very small, confused, glabrous on disc. Declivity very steep, very broadly convex; striae

more deeply impressed, interstriae half as wide as on disc, clothed with numerous, confused interstitial scales, each about one to two times as long as wide, base with a few much longer erect, rather slender scales, these decrease in length on upper third to length of ground scales.

Distribution: Venezuela: San Esteban, Carabobo; Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 429, *Serjania*, SLW; El Laurel, 12 km SW Caracas, Miranda, 1-V-1970, 1300 m, No. 462, *Serjania*, SLW.

Biology: Taken from axial pith tunnels in stems smaller than 1 cm in diameter.

Notes: The above treatment was based on 3 males, all of which I compared to the holotype.

Bothrosternus artestrigosus Schedl

Bothrosternus artestrigosus Schedl, 1939:722. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:215)

Diagnosis: Distinguished from *affinis* Eggers by the smaller, more distinct punctures at the base of the pronotum; by the more narrowly convex lower declivity; and by the more slender declivital vestiture with very sparse ground scales.

Male: Length 1.7–1.9 mm, 2.4 times as long as wide; color very dark brown, pronotum almost black. Frons as in *affinis* except lower third more distinctly impressed. Pronotum as in *affinis* except surface more dull, punctures slightly smaller. Elytra as in *affinis* except declivity more distinctly convex; declivital striae less distinctly impressed, interstitial setae of erect, almost uniseriate rows, each at least eight times as long as wide, almost as long as distance between rows, and sparse ground cover of short, almost scalelike, pointed setae, each almost four times as long as wide.

Distribution: Brazil: Nova Teutonia [Santa Catarina], 20-V-1935, F. Plaumann.

Notes: The above treatment was based on the male holotype and on 1 male paratype; both are from Brazil and are at NHMW, Wien. Bright & Skidmore (1997:44) report this species from Bolivia; I have not seen their specimens.

Bothrosternus rudis Wood, n. sp.

Bothrosternus rudis Wood: Holotype ♂; Brazil; USNM, Washington

Diagnosis: Distinguished from *subopacus* Schedl by the smaller size; by the abruptly, strongly impressed striae, with punctures obsolete on disc, impressed between obsolete punctures on declivity; by the interstriae being slightly narrower than striae on disc, half as wide on the declivity; punctures on the pronotum disc much larger, deeper, some confluent; and by other characters described below.

Male: Length 2.3 mm, 2.1 times as long as wide; color black. Frons moderately concave on median five-eighths from epistoma, two-thirds distance toward upper level

of eyes; surface of concave area reticulate, with many rather close punctures to above upper level of eyes; vestiture in concave area coarse, moderately long, rather abundant, on convex area above sparse, very short; antennal scape club-shaped, slightly shorter than club, with a small tuft of long hairlike setae; club 1.48 times as long as wide, weakly obovate, sutures 1 and 2 weakly procurved. Pronotum 0.94 times as long as wide; widest near middle of pronotum length, sides moderately arcuate on basal half, broadly rounded in front; median line on posterior two-thirds forming a subacute costa; punctures on basal half coarse, close, moderately deep, several on median half confluent; punctures with their interior obscurely reticulate; spaces between punctures less than half as wide as puncture; narrow median area on anterior fourth of pronotum length smooth, shining, with obscure punctures sparse; basal margin obscurely angulate; scutellum circular in outline, dorsal surface convex, displaced somewhat caudad into scutellar notch; glabrous. Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; striae abruptly, moderately impressed on disc, weakly on declivity; striae with punctures obsolete, obscure remnants near declivity bear minute strial setae; interstriae on disc slightly narrower than striae, half as wide at base of disc, surfaces of striae and interstriae obscurely reticulate, interstriae each with a uniseriate row of small punctures. Declivity steep, very broadly convex; striae less deeply impressed, on lower half coarse, deeply impressed punctures evident, becoming obsolete on basal half; interstriae less than half as wide as striae, punctures replaced by rather small, pointed tubercles; costal margin near apex flared slightly upward. Vestiture consisting of rows of minute strial setae near and on declivity, and rows of interstitial, rather stout setae on declivity, each seta on basal area about equal in length to two-thirds distance between rows, these setae shorter on lower half.

Distribution: Brazil.

Type material: The male holotype was taken in Brazil (probably Manaus or Mato Grosso?) by R.A. Beaver, Code TL 17. The holotype is in the U.S. National Museum, Washington.

Bothrosternus subopacus Schedl

Bothrosternus subopacus Schedl, 1963:217. Holotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:215)

Diagnosis: Distinguished from *hirsutus* Wood, *brevis* Eggers, and *truncatus* Eichhoff by the feebly impressed striae on the disc; by the distinctly impressed strial punctures; and by the absence of setae on the discal interstriae and the very minute interstitial setae on the declivity.

Female: Length 2.5–2.8 mm, 2.1 times as long as wide; color dark reddish brown, pronotum almost black. Frons broadly convex on upper third of area below upper level of eyes, shallowly, very broadly concave below; epistoma

with a low, transverse carina on median half; surface strongly reticulate, punctures very small, sparse, mostly on upper and lateral margins; sparse vestiture restricted to epistomal area below carina. Pronotum 0.81 times as long as wide; surface strongly reticulate, punctures obscure, rather small, shallow on anterior two-thirds at least twice as large on basal one-fourth; vestiture abraded. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae feebly impressed, punctures very small, distinctly, rather closely impressed; interstriae at least five times as wide as striae, surface strongly reticulate, punctures small (half as large as those of striae), moderately numerous, strongly confused, vestiture obsolete (or shorter than diameter of an interstitial puncture). Declivity rather broadly convex, steep; striae distinctly impressed, punctures twice as large as on disc; interstriae narrower than on disc, two and one-half times as wide as striae, punctures less numerous, mostly uniseriate. Vestiture restricted to declivity (or near), setae minute, inconspicuous, mostly shorter than twice diameter of an interstitial puncture.

Distribution: Brazil: Nova Teutonia [Santa Catarina], 27° 11' B, 52° 23' L, VII-1954, 300–500 m, F. Plaumann; Rio Grande do Sul, K.E. Hudepohl, Torres I-1959.

Notes: The above treatment was based on the female holotype and on 1 other female; both are from Brazil and are in NHMW, Wien.

Bothrosternus hirsutus Wood

Bothrosternus hirsutus Wood, 1985:271. Holotype ♂; Rancho Grande, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:215)

Diagnosis: Distinguished by the fine, moderately abundant, hairlike setae on pronotum and (confused) elytra.

Male: Similar to female except frons almost flat on lower half; declivital granules on interstriae smaller.

Female: Length 2.3–2.4 mm, 2.1 times as long as wide; color dull black. Frons almost flat on less than lower half, a moderately strong transverse carina at level of antennal insertion, its upper slope coarsely punctured, broadly convex above; smooth on median area of lower half, with a few small punctures at margins, rather coarsely reticulate-granulate above; sparse, long, inconspicuous fine hair on lower half. Pronotum 0.90 times as long as wide; sides rather strongly arcuate from base; surface rather finely, very shallowly, longitudinally strigose, crests weakly convex, comprising less than one-fourth of surface, dull; vestiture of very fine, long moderately abundant hair over entire surface. Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; basal margins almost costate, crenulations very weak; striae abruptly, distinctly impressed, punctures confluent, scarcely visible; interstriae almost three times as wide as striae, feebly convex at base, moderately convex at base of declivity; surface dull, minutely reticulate, punctures very small, obscure, mostly in two rows on each

interstriae at margins (confused in some specimens); vestiture of very fine, short and long hair intermixed to base. Declivity convex, steep; striae more deeply impressed; interstriae half as wide as on disc, moderately convex on basal half, each with a row of fine granules at least on upper half.

Distribution: Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 429, *Serjania*, No. 420, *Tabebuia* twigs, SLW.

Biology: Taken from axial pith tunnels in stems 0.5–2.0 cm in diameter.

Notes: The above treatment was based on the type series of 23 specimens.

Bothrosternus brevis Eggers

Bothrosternus brevis Eggers, 1933:15. Holotype ♀; Sao Paulo, Brazil; USNM, Washington (References in Wood & Bright c1992:215)

Diagnosis: Distinguished from *hirsutus* Wood by the more deeply, less closely impressed pronotal strigae, with much less abundant hair on pronotum and elytra; declivital setae coarser, less abundant.

Male: Similar to female except frontal carina absent.

Female: Length 2.4–2.6 mm (male 2.5 mm), 2.2 times as long as wide; color dark brown. Frons as in *hirsutus*. Pronotum as in *hirsutus* except sides less strongly arcuate, strigosities shorter, deeper, not as close; vestiture much less abundant. Elytra as in *hirsutus* except interstriae near base of declivity less strongly convex; vestiture on disc less abundant, shorter, on declivity erect bristles stouter, in uniseriate rows, with very few supplemental setae.

Distribution: Colombia to Brazil.

Brazil: Manaus, Amazonas, INPA Campus, 3-XII-1986, No. 011 F10; Porto Flor., Sao Paulo, 4-V-1959, 13001, J. Halik; Petropolis, III-1938, Shannon.

Colombia: 24 km E Barbosa, Antioquia, 18-VII-1970, 1200 m, No. 698, Lauraceae sp., SLW.

Biology: One male was taken from a pith tunnel in a twig.

Notes: The above treatment was based on 3 males and 3 females. I compared 1 female directly to the holotype. Bright & Skidmore (1997:44) report this species from Bolivia, Venezuela, and Dominicana; these specimens were not seen by me; they probably include more than 1 species.

Bothrosternus truncatus Eichhoff

Plate X

Bothrosternus truncatus Eichhoff, 1868:150. Holotype ♂; Venezuela; NHMW, Wien (References in Wood & Bright c1992:215)

Bothrosternus striatus Eggers, 1933:16. Holotype ♂; Venezuela; USNM, Washington (References in Wood & Bright c1992:215). *New synonymy*

Diagnosis: Distinguished from *brevis* Eggers by the reddish brown, mature color, by the presence of an epistomal callus (not a carina), and by slight differences in sculpture of the pronotum and elytra.

Male: Similar to female except smaller, rare (about 5–10 percent of long series), epistomal callus absent, pronotal punctures more distinct, less elongate, pronotum almost glabrous.

Female: Length 2.1–2.3 mm (1.8–1.9 mm in male), 2.1 times as long as wide; color reddish brown. Frons from flattened below level of ocular sinuation, a rather weak epistomal callus just above epistomal margin; convex and transversely etched above; sparse, fine hair on flattened area and laterally to upper level of eyes. Pronotum 0.90 times as long as wide; sides moderately arcuate; surface similar to *brevis*, fine, semirecumbent, rather sparse, hairlike setae to base. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; similar to *brevis* except declivity much more broadly convex, interstriae at base of declivity more strongly convex, declivital striae 1–3 narrower, interstriae distinctly wider, erect bristles stouter, often flattened, especially on disc.

Distribution: Venezuela: “Venezuela”; 9 km S Barrancas, Barinas, 5-XI-1969, 150 m, No. 118, *Serjania*, SLW; 40 km SE Socopo, Barinas, 7-II-1970, 150 m, No. 286, *Serjania*, SLW.

Biology: Taken from axial pith tunnels in stems 0.5–2.0 cm in diameter.

Notes: The above treatment was based on 256 specimens. The identity of this species was in doubt for more than a century because the holotype is a male. This holotype was examined and compared directly to males and females in my collections. My male homo-

type was compared directly to the holotype of *striatus* and was found to be identical.

GENUS *STERNOBOTHRUS* EGGERS

Sternobothrus Eggers, 1943:372. Type-species: *Bothrosternus cancellatus* Chapuis, original designation (References in Wood & Bright c1992:216)

Diagnosis: Sutures of antennal club straight; lateral margins of pronotum subacutely costate; prothoracic intercoxal piece normal (not transversely costate); propleural area not excavated or conspicuously pubescent; interstriae partly or entirely costate; myleophagus.

Description: Length 2.2–3.6 mm, 2.1–2.2 times as long as wide; color dark brown to black. Frons convex above, variously impressed and ornamented below (sexually dimorphic); eyes widely separated above, mesal margins sinuate in most species; antennal funicle 7-segmented, club elongate, with 2 straight sutures. Pronotum unarmed, surface punctured. Elytra with basal margins either forming a continuous costa or with a row of weakly formed crenulations, declivity convex, steep; vestiture minute, sparse.

Distribution: Wood & Bright (c1992:216) report 10 species from Mexico (Oaxaca) to Argentina.

Biology: The 3 species I have observed were axial pith borers in small stems. All 3 fed directly on host tissue.

Notes: The species *Sternobothrus lobatus* Schedl was transferred to the genus *Cortisinus* (tribe Phloeosinini).

Key to the Species of *Sternobothrus*

- 1. Striae more weakly, gradually impressed, without any rugose-reticulation, punctures fine, impressed, distinct; interstriae 1–4 each with a sparse row of rounded tubercles (except *rufonitidus*) 2
- Striae abruptly, distinctly impressed, and conspicuously rugose-reticulate; interstriae weakly convex to costate, smooth to reticulate, never with tubercles 4
- 2(1). Lateral margin of pronotum rather abruptly angulate (not truly costate); eye entire, no hint of sinuation or emargination on anterior margin; basal margins of elytra elevated, forming an almost continuous costa; declivital interstriae narrowly convex (almost subcostate), lower 1–3 each with row of fine, obscure tubercles; Brazil (Santa Catarina) to Paraguay; 2.8–3.0 mm *rufonitidus* Schedl
- Lateral margins of pronotum clearly costate; interstriae each with a row of tubercles from base to at least base of declivity, declivital interstriae more broadly convex 3
- 3(2). Declivital interstriae 1–8 each with a closely set row of moderately large, rounded tubercles from base to apex; vestiture on pronotum of fine, very long hair, some setae equal in length to combined width of three interstriae, strongly confused on disc, mostly in uniseriate rows on declivity; Bolivia (Cochabamba); 3.2 mm *pilosus* (Schedl)
- Declivital interstriae 1 and 2 without tubercles on lower two-thirds, a few small, scattered tubercles at bases of 1 and 2 and more extensively on 3–8; setae on pronotum and elytra shorter, less abundant, largely confined to declivity, very few longer than distance between indefinite rows; Brazil (Santa Catarina); 2.9 mm [*marginicollis* (Eggers) also fits here but frons concave to upper level of eyes] *vexator* (Schedl)

BOTHROSTERNINI

- 4(1). Discal interstriae usually uniseriately punctured (punctures sometimes obscure or weakly confused), appearing bicostate in one species, interstriae subreticulate (or micropunctate) in some species 5
- Basal one-third or more of disc with interstriae broadly, evenly convex, brightly shining, with punctures strongly confused 10
- 5(4). Elytral disc mostly shining, interstriae each with a row of coarse, close punctures, reticulation or micropunctures not clearly evident; interstriae I costae distinct at base of declivity, breaking into a subserrate series of rounded denticles to apex on 1–3, more poorly formed in lateral areas; pronotum strigose 6
- Elytral disc reticulate to densely micropunctate, interstitial costae longer, declivital tubercles smaller 7
- 6(5). Punctures on pronotum rather coarsely strigose; strial punctures distinctly impressed; declivital costae broken into rather coarse serrations; small interstitial setae evident on disc and declivity, slightly longer, strial setae evident on declivity; Paraguay; 2.1 mm *paraguayensis* (Schedl)
- Pronotal punctures finely strigose; strial punctures confluent, obscure, almost obsolete; declivital costae broken into weak serrations; interstitial setae not evident on disc, minute on declivity (their length equal to less than one-fourth width of an interstriae, strial setae not evident; Brazil (Santa Catarina); 1.9–2.0 mm *ater* (Schedl)
- 7(5). Discal interstriae bicarinate from base to mid-disc, mesal element then declining and absent by base of declivity, lateral carina gradually increasing in importance caudad then subdividing on lower declivity into rows of small tubercles; body, slender, 2.4 times as long as wide; Venezuela; *Nectandra*; 2.8–3.1 mm *bicostatus* (Schedl)
- Discal interstriae neither sulcate nor costate on more than basal half, modestly to conspicuously costate 8
- 8(7). All interstriae conspicuously, uniformly costate from near middle of disc to junction at or near 9 at apex, with no tubercles or granules on the costae; Brazil (Pernambuco to Sao Paulo); 2.3–2.6 mm *suturalis* (Eggers)
- Costae on declivity extend from its base to middle of declivity, 1 and 2 on lower half either with punctures or granules 9
- 9(8). Discal interstriae twice as wide as striae, punctures numerous, confused; declivital interstriae 1 and 2 with fine granules; Brazil (Sao Paulo); 1.8 m *pumilus* (Eggers)
- Discal interstriae only slightly wider than striae, punctures uniseriate except slightly confused on 3; declivital interstriae 1 and 2 punctured, granules absent; Brazil (Guanabara); 2.4 mm *transitus* (Schedl)
- 10(4). Sutural apex rather shallowly emarginate, apices of elytra distinctly explanate, their costal margins rather coarsely serrate; Panama and Venezuela to Peru and Brazil; *Nectandra*; 2.1–2.5 mm *bicaudatus* (Blandford)
- Elytra rather broadly to narrowly rounded behind, entire, costal margins near apex smooth; larger species 11
- 11(10). Slightly smaller, more slender species (2.2 times as long as wide); epistomal callus poorly developed; discal interstriae reticulate on at least margins of basal half; all declivital interstriae narrowly, about equally costate, punctures obsolete; Brazil; 2.4–2.7 mm *costatus* (Chapuis)
- Larger, stouter species (< 2.0 times as long as wide); epistomal callus (at least in male) more strongly developed; discal interstriae smooth, shining; either with no declivital interstriae carinate or carinae conspicuously unequal in height 12

- 12(11). Lower declivity convex, carina on interstriae 2 extending at least to middle of declivity, crest or carina on 3 ending slightly below middle; epistomal callus unarmed, reddish brown brush extending more than half distance to upper level of eyes, eye entire; Bolivia to Peru; 3.1 mm *carinatus* Eggers
- Lower declivity rather strongly impressed between interstriae 3; declivital interstriae 2 not carinate below base 13
- 13(12). Declivital interstriae tuberculate or subserrate, none with a smooth costa, 1–3 extend to apex; striae 1–10 rather coarsely rugose-reticulate on both disc and declivity; pronotum rather coarsely granulate except at lateral margins (male) and near base; male epistomal callus distinct, unarmed; Brazil (Santa Catarina); 3.6–3.8 mm *opaculus* Schedl
- Interstitial costae 1–9 forming uniform crests on posterior disc to at least upper half of declivity; striae not rugose-reticulate near base on disc or on lower half of declivity; pronotum smooth, with abundant small punctures 14
- 14(13). Male frons strongly concave on more than lower half, impression attaining upper level of eyes, lateral margins subacutely elevated from epistoma to slightly above level of antennal insertion, epistomal callus broad, its dorsal crest forming a subacute carina; discal interstriae smooth, shining, with numerous, confused punctures to lower declivity, not carinate; Brazil (Nova Fribourg); 4.0 mm *cancellatus* (Chapuis)
- Male frons moderately, subconcavely impressed on lower half, lateral margins weakly elevated, epistomal callus poorly formed, armed by a strong median tubercle and with a conspicuous reddish brown brush of setae above callus; all discal interstriae reticulate, punctured on only basal two-thirds of disc, carinate near and on declivity to near apex; Mexico (Oaxaca) to Argentina; *Nectandra*; 2.5–3.8 mm *sculpturatus* (Blandford)

Sternobothrus rufonitidus Schedl

Sternobothrus rufonitidus Schedl, 1952:351. Holotype ♀; Paraguay, Villarica; NHMW, Wien (References in Wood & Bright c1929:216)

Diagnosis: This species lacks an essential generic character, the lateral margins of the pronotum are subangulate to narrowly rounded, not fully costate; declivital interstriae weakly costate; anterior margin of eye entire, with no hint of sinuation; basal margins of elytra distinctly elevated, forming a continuous costa.

Male: Similar to female except upper frons strongly convex, impunctate area slightly larger, epistomal brush above stronger callus larger, of bright reddish brown color (yellowish in female).

Female: Length 2.8–3.0 mm, 2.0 times as long as wide; color very dark reddish brown. Frons subconcavely impressed on lower two-thirds of area below upper level of eyes, deepest point one-half distance from epistoma to upper level of eyes; upper half and continuing to vertex smooth, shining, impunctate; lower area shining and finely, deeply punctured and pubescent from epistomal callus to deepest point of concavity and continuing laterally to margin of eye; pubescence of coarse, rather abundant, moderately long hair; epistomal callus distinctly, weakly elevated on median half, smooth, shining. Pronotum 0.95 times as long as wide; surface smooth, shining, punctures very small, distinctly impressed, round to oval, spaced by 1–4 diameters of a puncture; glabrous.

Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; basal margins moderately elevated to continuous costa, slope with one row (weakly formed) as a submarginal undulating costa; striae narrowly, rather abruptly impressed, punctures small, distinctly impressed, interstriae twice as wide as striae, broadly convex to near declivity, smooth, shining, with numerous fine, confused punctures. Declivity broadly convex steep; striae more strongly impressed, punctures mostly obsolete; interstriae narrowly convex, almost subcostate from 1–9, 1–4 continue to apex, 5 and 7 join and also continue to apex; on lower half of 1–3 an obscure row of fine granules present. Glabrous.

Distribution: Brazil to Paraguay and Argentina.

Argentina: Cited in Wood & Bright c1992:216).

Brazil: Nova Teutonia [Santa Catarina], 17-II-1950, 4-V-1950, VII-1954, 300–500 m, F. Plaumann.

Paraguay: Villarica, IX-1932, Koller; Hohenan, X-1935, No. 3010, Jacob (DEI Muncheberg).

Notes: The above treatment was based on the female holotype, on the male allotype, on 1 other male and 1 female at NHMW, Wien, and on 3 females (at Muncheberg) that may have been taken with the holotype.

Sternobothrus pilosus (Eggers), n. comb.

Sternobothrus pilosus (Eggers), 1943:378 (*Cnesinus*). Holotype ♂; Bolivia (Cochabamba); NHMW, Wien (References in Wood & Bright c1992:210)

Diagnosis: Distinguished by the large size; by the stout body form; and by the very long, fine interstitial setae.

Male (?): Length 3.2 mm, 2.1 times as long as wide; color reddish brown. Frons with epistomal callus very poorly formed, its upper slope marked by 1 row of yellowish hair; lower half transversely impressed; broadly smooth, shining from epistoma to above upper level of eyes; hairlike vestiture of moderate length, mostly limited to lateral areas. Pronotum 0.90 times as long as wide; surface smooth, shining, punctures longitudinally strigose, most confluent, grooves narrow, moderately long, ridges mostly flat (not convex). Vestiture of moderately abundant, very fine, very long hair (almost as long as those on elytra). Scutellum twice as wide as long. Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; basal margins armed by a continuous costa, crenulations not indicated; striae distinctly impressed, punctures small, distinctly impressed; interstriae slightly convex, about three times as wide as striae, surface smooth, shining, each with a central, almost uniseriate row of subacutely pointed tubercles, and small, confused, moderately abundant punctures. Declivity broadly convex, steep (weakly impressed between left and right interstriae 3, particularly on 2); tubercles closer and slightly larger on declivity from 1 to about 9 (of reduced size in lateral areas). Vestiture of very fine, very long hair, many of greater length than combined width of three interstriae, on disc arising from both tubercles and punctures, on declivity almost entirely from tubercles; strial hair present but much shorter.

Distribution: Bolivia: Cochabamba, [F. Woytkowski].

Notes: The above treatment was based on the male holotype.

Sternobothrus vexator (Schedl), n. comb.

Sternobothrus vexator (Schedl), 1963:220 (*Cnesinus*). Holotype ♂; Brasilien: Santa Catarina, Nova Teutonia; NHMW, Wien (References in Wood & Bright c1992:212)

Diagnosis: Distinguished from *pilosus* (Eggers) by the shorter, less abundant setae on pronotum and elytra; and by the absence of tubercles on the lower half of declivital interstriae 1 and 2.

Male: Similar to female except epistomal brush less than half as extensive, frontal impression extending almost to upper level of eyes; smooth and shining only on lower half, upper area transversely etched to upper level of eyes, lateral areas with small tubercles replacing punctures.

Female: Length 2.9 mm, 2.3 times as long as wide; color reddish brown. Frons with epistomal callus occupying more than central half, very short (longitudinally), reddish brown brush occupying lower one-third of area below upper level of eyes; smooth, shining, impunctate area on lower half as wide as distance between eyes above, extending from brush to vertex (constricted above

eyes); lateral areas rugose-reticulate and finely punctured, a few fine, moderately long setae present. Pronotum 0.90 times as long as wide; shining; longitudinal striations short, about half confluent, most punctures on basal fourth moderately elongate, few strigose; almost glabrous. Elytra 1.6 times as long as wide, 1.9 times as long as pronotum; striae very narrow, distinctly, weakly impressed, punctures very small, some indistinct; interstriae about six times as wide as striae, weakly convex, almost smooth, with sparse, confused, minute punctures and on interstriae 1–4 sparse, uniseriate, rounded tubercles of moderate size. Declivity broadly convex, rather steep; strial punctures larger and much deeper than on disc; interstriae 2 weakly impressed, 1 punctured and devoid of tubercles on lower two-thirds, 2 on lower half, 3 and 4 with tubercles to lower one-fourth. Vestiture very sparse on disc, of moderately abundant, erect, stout setae, confused on declivity, longest slightly longer than width of an interstriae.

Distribution: Brazil: Santa Catarina, 27°11'N, 52°23'W, II-1960, 300–500 m, F. Plaumann.

Notes: The above treatment was based on the male holotype and female allotype.

Sternobothrus marginicollis (Eggers), n. comb.

Sternobothrus marginicollis (Eggers), 1931:15 (*Cnesinus*). Holotype ♂; Tropisches America (Antillen oder Colombien); MNB, Berlin (References in Wood & Bright c1992:209)

Diagnosis: Distinguished by absence of interstitial costae; interstriae five times as wide as striae, their surface reticulate-micropunctate rows of tubercles present on disc and declivity.

Male: Length 3.5 mm, 2.1 times as long as wide; color dark brown. Frons shallowly, broadly concave from epistoma to above upper level of eyes; surface smooth, shining, with moderately abundant, minute punctures uniformly distributed; vestiture of fine, short, inconspicuous hair; epistomal callus moderately distinct, its upper slope ornamented by one row of yellowish brown setae. Pronotum 0.93 times as long as wide; surface smooth, shining, rather closely, coarsely, longitudinally strigose from base almost to anterior margin, punctures not clearly evident; almost glabrous except near margins. Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; striae abruptly, narrowly, moderately impressed, punctures small, shallow, obscure; interstriae about five times as wide as striae, surface a combination of micropunctures and reticulation, 1 with a uniseriate row of small, rounded tubercles, remaining interstriae with tubercles usually wider, often subcrenulate. Declivity broadly convex, steep, area between left and right interstriae 3 weakly impressed; surface more strongly reticulate, each interstriae with a uniseriate row of rounded tubercles of moderate size from base to apex. Vestiture mostly on declivity, abraded, of stout, hairlike setae, rather sparse.

Distribution: "Antillien?, Columbien, 48412."

Notes: The above treatment was based on the male holotype.

Sternobothrus paraguayensis (Schedl), n. comb.

Sternobothrus paraguayensis (Schedl), 1936:107 (*Cnesinus*). Holotype ♀; Paraguay; NHMW, Wien (References in Wood & Bright c1992:210)

Diagnosis: Allied to *transitus* (Schedl) but distinguished by the smaller size; by the smoother elytral disc; and by the larger interstitial punctures.

Female: Length 2.1 mm, 2.6 times as long as wide; color very dark brown. Frons with epistomal callus rather broad but very short, brush with its upper slope large, about 6 ranks deep; transverse impression rather strong, short; central, shining, impunctate area extending to upper level of eyes (partly concealed above by pronotum), setae on lateral margins coarse, rather long. Pronotum 1.03 times as long as wide; pronotum shining, coarsely, deeply strigose; sparse, rather short setae restricted to anterior one-fourth. Elytra 1.6 times as long as wide, 1.8 times as long as pronotum; striae abruptly, rather narrowly, distinctly impressed, punctures almost completely confluent; interstriae about twice as wide as striae, shining, punctures rather coarse (almost as large as striae punctures), uniseriate. Declivity broadly convex, rather steep; striae impressed, punctures not discernible; interstriae as wide as striae, 1–6 each with a row of rather coarse (somewhat rounded) serrations (about 6–10 on each) from base to junction with 9. Vestiture of mostly uniseriate interstitial setae, each on basal half of disc about half as long as distance between rows, two-thirds as long near and on declivity; striae setae present, of very fine hair, each about half as long as interstitial setae.

Distribution: Paraguay: "Paraguay."

Notes: The above treatment was based on the female holotype.

Sternobothrus ater (Schedl), n. comb.

Sternobothrus ater (Schedl), 1952:352 (*Cnesinus*). Holotype ♀; Brasilien, Santa Catarina; NHMW, Wien (References in Wood & Bright c1992:205)

Diagnosis: Distinguished from *paraguayensis* Schedl by the finer strigose punctures of the pronotum; by the weaker, subserrate, interstitial costae on the lower declivity; by the striae punctures; by the smaller interstitial punctures on the disc; and by the shorter to obsolete striae and interstitial setae.

Female: Length 1.9–2.0 mm, 2.4 times as long as wide; color very dark brown. Frons about as in *paraguayensis*, impunctate median area above about one-fourth as wide as distance between eyes, vestiture above epistomal brush apparently more abundant and larger. Pronotum resembling *paraguayensis*, shining, finely, longitudinally strigose, most punctures confluent. Elytra resembling *paraguayensis*; striae rugose-reticulate from base to apex,

punctures almost obsolete on disc and declivity; interstriae mostly smooth, shining (some reticulation present), low, subacute costae from near base of declivity to near apex, becoming finely subserrate on lower half of declivity. Strial setae obsolete; interstitial setae near and on disc very short, less than one-fourth as long as width of an interstriae.

Distribution: Brazil: Santa Catarina, Kollar Coll. (type); Nova Teutonia, Santa Catarina, 27° 11. B, 52°23L, VII-1954, 300–500 m, F. Plaumann.

Notes: The above treatment was based on the female holotype and on 1 other female that had been labeled by Schedl as a male.

Sternobothrus bicostatus (Schedl), n. comb.

Sternobothrus bicostatus (Schedl), 1936:106 (*Cnesinus*). Holotype ♂; Costa Rica: Turrialba; NHMW, Wien (References in Wood & Bright c1992:206)

Diagnosis: Interstriae bicostate at least on basal half of disc, lateral element continuing to lower declivity.

Male: Similar to female except concave area on frons smaller, not as deep, its setae less numerous, shorter; declivital bristles apparently shorter, weaker.

Female: Length 2.8–3.1 mm, 2.4 times as long as wide; color almost black. Frons broadly, moderately concave from epistoma to very slightly below upper level of eyes; surface of concave area shining, coarsely, closely punctured and with rather long, moderately abundant, erect, subplumose setae on lower two-thirds, median area above almost smooth, shining, glabrous; area above concavity transversely flattened, its surface reticulate-granulate, with small punctures at upper and lateral margins. Pronotum 1.0 times as long as wide; shining; posterolateral areas with fine elongate punctures, becoming finely, continuously strigose mesad and cephalad to anterior one-tenth, punctures not discernible on middle half; glabrous. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; basal margins weakly crenulate; striae moderately impressed, punctures confluent, not discernible; interstriae about twice as wide as striae, bicostate at base, mesal element obsolete before declivity, area between costae continuing to declivity, dull, reticulate, obscurely, minutely punctured, with numerous microsetae on both sides of major costae from base to declivity. Declivity broadly convex, steep; striae more deeply impressed, interstriae much narrower than on disc, costae end before middle, continued to apex as rows of moderately large, rounded tubercles; each interstriae with a row of small slender bristles of moderate length, each about two-thirds as long as distance between rows, spaced within a row by less than length of a bristle; minute striae setae present.

Distribution: Costa Rica to Venezuela.

Venezuela: Colonia Tovar, Aragua, 4-V-1970, 1700 m, No. 485, *Nectandra*, SLW; Carbonera Experimental Forest, 50 km airline NW Merida, Merida, 14-X-1969, 2500 m, No. 53, *Nectandra*, SLW.

Biology: Taken from axial pith tunnels in small branches.

Notes: The above treatment was based on 1 male and 6 females from Venezuela; 1 female was compared to the holotype by me.

Sternobothrus suturalis (Eggers), n. comb.

Sternobothrus suturalis (Eggers), 1931:32 (*Bothrosternus*). Holotype ♂; Sao Paulo, Brasil; NMPC Prague (References in Wood & Bright c1992:215)

Diagnosis: Distinguished from other members of this genus by having all nine interstitial costae extending from the middle of the disc to their normal apex on the lower half of the declivity.

Male: Length 2.3–2.6 mm, 2.4 times as long as wide; mature color dark reddish brown to almost black. Frons rather strongly, transversely convex on lower half of area from epistoma to upper level of eyes, upper half broadly convex; epistomal callus with flattened, median tubercle; surface reticulate on more than dorsal half, shining below, lower half and marginal areas above with moderately abundant, fine punctures; vestiture of moderately abundant, rather long hair on lower half and lateral areas above. Pronotum 1.1 times as long as wide; widest at middle, dorsal profile evenly arched; surface smooth, shining, anterior and lateral areas with some reticulation, punctures rather small, moderately abundant, shallow, oval in shape, each about three times as long as wide; glabrous. Elytra 1.6 times as long as wide, 1.9 times as long as pronotum; costa on basal margins acutely, uniformly elevated; striae moderately, abruptly impressed, punctures obscure, confluent, surface rugose-reticulate; interstriae less than twice as wide as striae, broadly convex on slightly more than basal half, subacutely, evenly costate on almost posterior half of disc and on declivity to apex, basal area partly to mostly reticulate, costae smooth, shining. Declivity convex, moderately steep, feebly impressed between left and right interstriae 3; interstitial costae continue to apex (where costa meets 9) except 4 and 6 end short, without any tubercles or serrations. Strial setae obsolete; interstitial setae obsolete on disc, on declivity each costa with a row of minute, hairlike setae on each side of costa.

Distribution: Brazil: Saude [Bahia], 16-VII-1914, J. Melzer; Pery Pery, Pernambuco, 6-V-1892, Gounelle; Caruaru, Pernambuco, IV-1972, M. Alvarenga; Este Sao Paulo, Sao Paulo.

Hosts: *Araucaria angustifolia* (Bright & Skidmore 2002:34).

Notes: The above treatment was based on 4 males, 1 of which was compared by Eggers directly to the holotype.

Sternobothrus pumilus (Eggers), n. comb.

Sternobothrus pumilus (Eggers), 1931:34 (*Cnesinus*). Holotype ♂; Sao Paulo, Brazil; USNM, Washington (References in Wood & Bright c1992:211)

Diagnosis: Distinguished by the finely, densely, longitudinally strigose pronotum; by the interstitial carinae restricted to the basal half of the declivity; and by the subacute lateral margins of the pronotum.

Male: Length 1.8 mm, 2.4 times as long as wide; color black. Frons transversely, subconcavely impressed on lower half, deepest at level of antennal insertion; epistomal elevation on median one-third appearing as an obscure, transverse carina; surface obscurely punctate-granulate from epistoma almost to upper level of eyes except median one-fourth on upper half smooth, shining, impunctate; vestiture fine, rather sparse, inconspicuous, mostly on lower half and lateral areas above. Pronotum 1.0 times as long as wide; surface subshining, finely, densely, longitudinally strigose (grooves and ridges of equal width); almost glabrous. Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; row of crenulations on basal margins weak, about a dozen, submarginal crenulations; striae abruptly, rather weakly impressed from base to apex, surface minutely rugose-reticulate from base to mid-declivity, fine punctures obscure to obsolete; interstriae twice as wide as striae, subshining, partly, weakly subreticulate, punctures numerous, not always clearly impressed, confused; interstriae at or near base of declivity subcarinate to weakly carinate. Declivity convex, steep; interstriae 1 not elevated, with a few fine, obscure granules, 2 feebly elevated at base, with about 12 small tubercles extending to apex, 3 subacutely costate except obsolete on lower one-fourth, 4–9 subacutely costate almost to their apices; costal margin near apex slightly elevated. Vestiture obsolete except of minute hair on declivity.

Distribution: Brazil: Sao Paulo.

Notes: The above treatment was based on the male holotype.

Sternobothrus transitus (Schedl), n. comb.

Sternobothrus transitus (Schedl), 1976:63 (*Cnesinus*). Holotype ♀; Corcovado, Guanabara, Brazil; NHMW, Wien (References in Wood & Bright c1992:212)

Distinguished from *pumilus* (Eggers) by the larger size; by the narrower discal interstriae; and by the absence of granules on declivital interstriae 1 and 2.

Female: Length 2.4 mm, 2.5 times as long as wide; color very dark reddish brown. Frons with epistomal callus on median one-fifth, almost as long as wide, reddish brown brush broad, occupying lower one-third of area below upper level of eyes; central half of upper half smooth, shining, impunctate, lateral areas dull, subreticulate, closely, rather coarsely punctured, with several stout, moderately long setae. Pronotum 1.2 times as long as wide; surface shining, finely, closely, longitudinally strigose on anterior half, more coarsely near base; several large, shallow punctures at base, their interiors rugose-reticulate. Elytra 1.9 times as long as wide, 1.8 times as long as pronotum; striae distinctly impressed, rugose-reticulate, punctures large, confluent, obscure;

interstriae reticulate-micropunctate, slightly wider than striae, small, obscure punctures uniseriate except mostly confused on 3. Declivity broadly convex; interstriae rather weakly carinate at base, ending higher on 1 and 2, at middle on 3 and 4, 1 with punctures to apex (no granules), 2–4 with a few granules. Glabrous on disc; sparse, uniseriate rows of hair on declivity.

Distribution: Brazil: Guanabara, Corcovado, XI-1970, Alvarenga & Seabra.

Notes: The above treatment was based on the female holotype.

Sternobothrus bicaudatus (Blandford)

Sternobothrus bicaudatus (Blandford), 1896:133 (*Bothrosternus*). Syn-types 2, sex?; Volcan de Chiriqui, Chiriqui, Panama; BMNH, London (References in Wood & Bright c1992:216)

Sternobothrus tuberculatus Eggers, 1951:152. Holotype ♀; Blumenau, Brazil; NHMW, Wien (References in Wood & Bright c1992:216).
New synonymy

Diagnosis: Interstriae flat on basal half of disc, costate on posterior disc and declivity; sutural apex emarginate, elytral apices explanate, their costal margins serrate.

Male: Similar to female except epistomal callus greatly reduced, reddish brown brush absent.

Female: Length 2.1–2.5 mm, 2.4 times as long as wide; color almost black, elytra usually dark reddish brown. Frons broadly convex on upper two-thirds, smooth, shining, impunctate, a few setae in lateral areas; rather strongly, transversely impressed from epistoma to slightly above level of antennal insertion; shining epistomal callus broadly (transversely), narrowly elevated, its upper slope ornamented by a large brush of laterally flattened reddish brown setae filling at least half of impressed area, a few yellowish setae above brush and laterally. Pronotum 1.06 times as long as wide; sides straight and parallel on more than basal half; surface smooth, shining behind, reticulate on anterior third, punctures fine, oval, separate, not strigose. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; basal margins forming an acute, continuous costa; striae moderately impressed, punctures confluent, not discernible; interstriae almost flat and twice as wide as striae on basal half of disc, becoming convex and as wide as striae by base of declivity, surface smooth, shining, punctures small, confused. Declivity convex, steep, sutural apex emarginate, elytral apices explanate, their costal margins serrate (visible from dorsal aspect); interstriae subacutely costate at base, becoming serrate on upper third, continued to apex as rows of narrow, subacute tubercles; vestiture confined to declivity, of minute, fine hair (not in rows).

Distribution: Panama to Brazil.

Brazil: Blumenau [Santa Catarina]; 260 km N Xavantina, Mato Grosso (12°31'S, 51°0'W), RA. Beaver.

Peru: Almirante, Dep. San Martin, 12-XII-1936, 1900 m, F. Woytkowski.

Venezuela: 7 km W Socopo, Barinas, 13-II-1970, 200 m, No. 322, *Nectandra*, SLW.

Hosts: *Guatteria*, *Hirtella*, *Ocotea*, *Protium*, *Siparuna guianensis* were reported by Bright & Skidmore (1997:45); these specimens were not seen by me.

Biology: Taken from axial pith tunnels in small branches of a cut seedling.

Notes: The above treatment was based on the 2 syntypes of *Bothrosternus bicaudatus* Blandford, on 1 female from Brazil, 1 female from Peru, 18 specimens of both sexes from Venezuela in my collection, and on the female holotype of *Sternobothrus tuberculatus* Eggers.

Sternobothrus costatus (Chapuis)

Sternobothrus costatus (Chapuis), 1869:25 (*Bothrosternus*). Lectotype ♀?; Bresil; IRSNB, Brussels, present designation (References in Wood & Bright c1992:216)

Bothrosternus lacordairei Chapuis, 1869:25. Holotype ♂; Bresil, Nova Fribourg; IRSNB, Brussels (References in Wood & Bright c1992:216). *New synonymy*

Diagnosis: Distinguished by the more slender body form; by the reticulate discal interstriae; and by the equally costate declivital interstriae.

Male: Length 2.3–2.7 mm, 2.2 times as long as wide; color almost black. Frons rugose-reticulate above, smooth, shining on lower fourth of area below upper level of eyes, punctures small, obscure, close; small median area slightly above level of antennal insertion, shallowly concave; subglabrous; epistomal callus very weak. Pronotum 1.03 times as long as wide; surface smooth, shining, except reticulate on anterior fourth, punctures small, moderately close, oval to about twice as long as wide; glabrous, except sparse, short hair near anterior margin. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; basal margins a continuous costa; striae distinctly, moderately impressed, rugose-reticulate, punctures obsolete; interstriae broadly, rather weakly convex, reticulate, rows of close, minute punctures on each margin. Declivity broadly convex, moderately steep; interstriae equally, subacutely costate from just before base to near apex, 1–3, 5, and 9 attain apex, others end short; glabrous. Abdominal sternum 5 concave.

Female: Similar to male except frons with impression not as strong, convex area above weaker, vestiture on lower half and lateral areas longer, more abundant, reddish brown in color.

Distribution: Brazil: Nova Fribourg, Deyrolle; Sierra de Communitay [Recife or Pernambuco], 3-XII-1893; Talemaco Borba, Para, 1984, *Araucaria angustifolia*, C. Moreira, also 4-IV-1996, ethanol trap, *Pinus taeda* stand; Monte Alegre, Para, 25-VIII-1995, ethanol trap, C.A.H. Flechtman; Sao Paulo, S.P.

Hosts: *Araucaria angustifolia*.

Notes: The above treatment was based on the male holotype of *lacordairei* and the 2 Chapuis female (?) syntypes of *costatus*. The first of these syntypes is here designated as the lectotype of *Bothrosternus costatus* Chapuis. Specimens in the DEI, Munchenberg were identified by Schedl as *suturalis*. There were 21 other specimens examined from Brazil (Para).

Sternobothrus carinatus Eggers

Sternobothrus carinatus Eggers, 1943:273. Holotype ♀; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:216)

Diagnosis: Lower declivity convex, costae on interstriae 2 and 3 extending to or below middle of declivity; epistomal callus unarmed.

Female: Length 3.1 mm, 1.9 times as long as wide; color black, elytra dark brown. Frons shallowly concave from level just below ocular situation to epistomal callus, concavity filled by a dense brush of reddish brown hair of uniform length; epistomal callus poorly formed; area above abrupt margin of concavity to upper level of eyes smooth, densely covered by micropunctures, glabrous. Pronotum 1.05 times as long as wide; arcuate sides converging cephalad from base; basal area smooth, shining, reticulate on anterior third, punctures small, close, round to oval in shape, not strigose. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; basal margins forming a continuous costa, a few submarginal crenulations on interstriae 2, 3; striae rather strongly impressed, punctures confluent, reticulate at base of declivity; interstriae twice as wide as striae on basal half of disc, weakly convex at base of disc, rather strongly convex by base of declivity, surface smooth, shining, punctures small, confused. Declivity broadly convex, steep; striae more deeply impressed, interstriae narrower than on disc, each subacutely costate to below middle of declivity or below, represented by weak punctures or obscure granules near apex; glabrous.

Distribution: Bolivia to Peru.

Bolivia: Cochabamba [F. Woytkowski].

Peru: Rioja, Dept. San Martin, 9-IX-1936, 900 m, F. Woytkowski.

Notes: The above treatment was based on the holotype, and on 1 female from Peru.

Sternobothrus opaculus Schedl

Sternobothrus opaculus Schedl, 1963:218. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:216)

Diagnosis: Distinguished from *cancellatus* (Chapuis) and *sculpturatus* (Blandford) by the subserrate declivital interstriae 1–9; by the uniformly rugose-reticulate striae from base to apex.

Male: Similar to female except frons with smooth area replaced by minute, transversely etched rugulation, setae less abundant, shorter, epistomal callus weaker but present; basal one-fourth of pronotum smoother, with dense, shallow, small and minute punctures intermixed; crenulations at base of elytra slightly coarser.

Female: Length 3.6–3.8 mm, 2.1 times as long as wide; color very dark reddish brown. Frons with a strong, transverse impression one-third length from epistoma to upper level of eyes; upper area broadly convex, central three-fifths impunctate and brightly shining to well

above upper level of eyes; lateral margins and transverse impression with rather dense, long reddish brown hair to epistomal callus; transverse callus conspicuous, smooth, shining, modestly elevated on median three-fourths of epistoma. Pronotum 0.90 times as long as wide; shining, punctures not clearly evident, entire surface rather finely, closely, uniformly rugose (not strigose) from anterior margin to base (no smooth areas); vestiture absent. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; basal margins weakly subcrenulate, bases of interstriae 2–4 with weak submarginal crenulations; striae dull, rather broadly, moderately impressed and strongly, uniformly rugose-reticulate from base to apex, minute, obscure punctures indicated in some areas; interstriae distinctly wider than striae, surface smooth, shining (often with margins rugose-reticulate), punctures rather fine, close, confused. Declivity broadly convex, rather steep, shallowly sulcate between interstriae 3; striae narrower than on disc; interstriae 1–9 narrower than on disc, punctures mostly eliminated, convex, 3, 5, 7, and 9 distinctly higher, their crests subserrate, not clearly dentate, apex of 1 joins costal margin, 3 joins 9, 2 almost attaining costal margin. Vestiture absent, except minute, uniseriate interstitial hair on lower declivity, none as long as twice diameter of discal puncture.

Distribution: Brazil: Nova Teutonia [Santa Catarina], 27°11'N, 52°23'W, II-1964, 300–500 m, F. Plaumann.

Notes: The above treatment was based on the male holotype and female allotype of *opaculus*, both from Brazil. Schedl had the sexes reversed in the original description.

Sternobothrus cancellatus (Chapuis)

Sternobothrus cancellatus (Chapuis), 1869:25 (*Bothrosternus*). Holotype ♂; Nova Fribourg, Brazil; IRSNB, Brussels (References in Wood & Bright c1992:216)

Diagnosis: Distinguished by the large size; by the smooth, shining discal interstriae; and by the absence of costae on all declivital interstriae.

Female: Length 4.0 mm, about 2.0 times as long as wide; color black. Frons rather deeply concave from epistoma to well above upper level of eyes; surface smooth, shining, with sparse, minute punctures on more than upper half, finely subgranulate on lower fourth; lateral margins acutely elevated on lower half to epistoma; epistomal callus moderately elevated on median half, its upper margin subcarinate on median third; a tuft of hair on mesal surface of lateral elevation at junction with epistoma, a fringe of rather short hair on lateral margin of upper half of impressed area; concavity glabrous. Pronotum about 1.1 times as long as wide; surface smooth, brightly shining, punctures minute in central area, slightly larger toward lateral and anterior margins; glabrous. Elytra about 1.7 times as long as wide, 1.6 times as long as pronotum; basal margins with a partial, weak costa near scutellum; scutellar notch deep, broadly U-shaped; striae narrowly, moderately impressed,

punctures small, clearly impressed on about basal half, confluent and obsolete toward declivity; interstriae smooth, shining, moderately convex (not costate), punctures numerous, fine, confused. Declivity broadly convex, obscurely sulcate between left and right interstriae 3; rather steep; interstriae 1 and 3–9 convex, not costate, with numerous, close, confused punctures (except uniseriate on 1), none costate; 2 moderately flat with uniseriate punctures; 3 and lateral areas weakly elevated; glabrous. Abdominal sternum 5 concave.

Distribution: Brazil: Nova Fribourg, Deyr.

Notes: The above treatment was based on the male holotype.

Sternobothrus sculpturatus (Blandford)

Sternobothrus sculpturatus (Blandford), 1896:132 (*Bothrosternus*).
Lectotype ♀; Bugaba, Chiriqui, Panama; BMNH, London, designated by Wood 1982:254 (References in Wood & Bright c1992:216)

Diagnosis: Lower declivity rather strongly impressed, costa on interstriae 2 obsolete, 3 more strongly elevated, this costa continued from base to apex of 3; female epistomal callus armed by a conspicuous median tubercle.

Male: Length 2.5–3.8 mm, 2.0 times as long as wide; color black. Frons convex from just above level of antennal insertion to upper level of eyes, this area almost smooth, shining in central area, finely punctured and pubescent laterally; lower area rather strongly, transversely impressed from epistoma to base of convexity; epistomal callus distinct on median third, armed on median line by a large tubercle, in some specimens a weak carina extending dorsad from summit of tubercle to base of upper convexity; most of impressed area filled by a dense brush of reddish brown setae of moderately

long, uniform length. Pronotum 0.87 times as long as wide; surface minutely reticulate; punctures very small, moderately abundant, each almost round. Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; basal margins forming a continuous costa on median area, weakly crenulate laterally, with submarginal crenulations on interstriae 2–5; striae strongly impressed, punctures mostly confluent; interstriae less than twice as wide as striae, moderately convex at base, strongly convex near declivity; smooth, shining, small punctures confused. Declivity rather steep, shallowly sulcate between left and right interstriae 3; interstriae 3–9 subacutely costate to their apices, 1 and 2 convex (not costate), conspicuously impressed below level of 3; disc glabrous, very minute interstriae hair on declivity.

Female: Similar to male except epistomal brush very small, callus smaller; discal interstriae reticulate.

Distribution: Mexico (Oaxaca) to Argentina.

Argentina: Cited in Wood & Bright (c1992:216).

Brazil: Nova Teutonia, Santa Catarina, I-1931, F. Plaumann.

Colombia: 24 km E Barbosa, Antioquia, 18-VII-1970, 1200 m, No. 694, *Xelopia*, SLW.

Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 431, *Nectandra*, SLW; 8 km SW Bumbum, Barinas, 11-II-1970, 150 m, No. 328, *Nectandra*, SLW; III-1970, 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 272, *Nectandra* (Laurel Roja), SLW.

Biology: Specimens were taken from axial pith tunnels in stems 2–5 cm in diameter.

Notes: The above treatment was based on 2 specimens from Brazil, 1 from Colombia, 49 from Venezuela, and 58 from Central America.

TRIBE PHLOEOTRIBINI

Description: Frons sexually dimorphic, male variously impressed, female flat to convex; eye entire; funicle 5-segmented, club simple and very slender to strongly asymmetrical, deeply divided into 3 movable, usually sublamellate segments; procoxae contiguous; pronotum with or without asperities, its lateral margins rounded; metatergum fused to its postnotum (Wood 1986).

Biology: All species are monogynous and phloeophagous. Parental galleries are biramous and often engrave the wood rather deeply. Eggs are placed in niches and packed in frass. Larval mines radiate from the parental gallery and usually do not cross one another. In thin-barked hosts maturing larvae may engrave the wood rather deeply. Among those species that infest lianas, the larvae may bore deeply and destroy most host tissue. One species, *ingae* Wood, breeds in the fruiting pods of its host.

Taxonomy: Of the 2 genera that comprise this tribe, only 1 occurs in South America. It is readily apparent that this tribe arose in South America and spread to Australia prior to the Tertiary, when it was possible to do so; and to North America after the Tertiary; and from there to Asia and Europe during more recent interglacial periods.

GENUS *PHLOEOTRIBUS* LATREILLE

- Phloeotribus* Latreille, 1796:50. Type-species: *Hylesinus oleae* Fabricius = *Scolytus scarabaeoides* Bernard (objective synonyms), monobasic (Synonymy and references in Wood & Bright c1992:217–235)
- Phloeophthorus* Wollaston, 1854:299. Type-species: *Phloeophthorus perfoliatus* Wollaston
- Dryotomus* Chapuis, 1869:46. Type-species: *Dryotomus puberulus* Chapuis, monobasic, preoccupied by Swainson 1831:301

- Phthorophloeus* Rey, 1885:128. Type-species: *Phthorophloeus* Rey, 1885:128, monobasic
- Elzearius* Guillebeau, 1893:64. Type-species: *Elzearius crenatus* Guillebeau, monobasic
- Eulytocerus* Blandford, 1897:161. Type-species: *Eulytocerus champi- oni* Blandford, monobasic
- Comesiella* DelGuercio, 1925:218. Type-species: *Comesiella sicula* DelGuercio = *Phloeophthorus pubifrons* Guillebeau, monobasic
- Neophloeotribus* Eggers, 1943:349. Type-species: *Phloeotribus nubilus* Blandford, subsequent designation by Wood 1983:648
- Dryotomicus* Wood, 1962:76. Type-species: *Dryotomus puberulus* Chapuis, automatic, replacement name for *Dryotomus* Chapuis

Diagnosis: The very distinctive sublamellate, movable segments of the antennal club distinguish this genus from all other Scolytidae.

Description: Lateral margins of protibia armed by several socketed denticles; lateral margins of pronotum rounded; ventral or lateral margin of each segment in antennal club weakly to profoundly extended into a sublamellate process. Female frons of all species bearing a small median fovea just above upper level of eyes (not mentioned in the following descriptions).

Biology: All species are monogynous and breed in phloem tissue. The parental tunnels are biramous and mostly transverse. The larvae make individual mines in the phloem.

Notes: It is apparent that this tribe originated in South America based upon the large number of species and the diversity of forms that occur there. Of the 109 species listed by Wood & Bright (c1992:217–235), 53 occur in South America and an additional 17 in Central America. A few species occur in Asia, Europe, and North America, including Mexico.

Key to the Species of *Phloeotribus*

- 1. Male epistoma not subacutely elevated, without a transverse carina; pronotum variable, with or without asperities; interstriae variable, one to three times as wide as striae, setae either confused or uniseriate 2
- Male epistoma bearing and acutely elevated transverse carina; male scape usually bearing a conspicuous tuft of hair; some pronotal asperities always present; interstriae as wide as striae, each interstriae with a central, uniseriate row of setae 40
- 2(1). Body more slender, more than 1.8 times as long as wide; basal margin of pronotum transversely straight, median area not noticeably extended into scutellar notch; variable 3
- Body very stout, less than 1.6 (1.8 in *opacicollis*) times as long as wide; basal margin of pronotum with median area conspicuously extended caudad into scutellar notch; male antennal insertions usually displaced slightly mesad; striae abruptly, narrowly impressed, interstriae at least twice as wide as striae; male scape usually bearing a conspicuous tuft of hair 30

SCOLYTIDAE OF SOUTH AMERICA

3(2).	Lateral margin of male frons armed at level of antennal insertion by a moderately large, acutely pointed denticle; setae on discal interstriae fine, long, confused	4
—	Lateral margins of male frons without a pair of sharply pointed denticles at level of antennal insertion, rounded elevations sometimes present; interstitial setae on disc uniseriate except confused in <i>collaris</i> , <i>nanus</i>	6
4(3).	Declivital interstriae 1 and 2 unarmed, 2 constricted, 3 and posterior part of 9 conspicuously elevated and serrate; crenulations on lateral areas of pronotum weak to absent; Peru; 3.0–3.1 mm	<i>hylurgulus</i> Schedl
—	Declivital interstriae 1 and 2 each armed by a row of fine tubercles, 3 and 9 not elevated, their tubercles equal in size to those of adjacent interstriae; anterior and lateral areas of pronotum finely to moderately crenulate; smaller species	5
5(4).	Male frons less extensively excavated, concavity ending slightly above upper level of eyes, several conspicuous granules on upper fourth of concavity; disc on posterior half of pronotum more finely punctured, few circular, most transversely rugose; longest interstitial setae equal in length to combined width of two striae plus two interstriae; Peru; 2.2–2.5 mm	<i>pilifer</i> Wood
—	Male frons more broadly, more deeply excavated to well above upper level of eyes, a few very minute granules near upper margin within concavity; disc on posterior half of pronotum closely, deeply punctured, punctures almost circular, rugose only at posterior margin; longest interstitial setae equal in length to combined width of one striae and one interstriae; Venezuela; unidentified liana; 2.1–2.5 mm	<i>hirticulus</i> Wood
6(3).	Discal striae narrow, rather strongly impressed, punctures small; interstriae about two or more times as wide as striae, interstitial setae rather abundant, confused	7
—	Discal striae weakly to moderately impressed, about equal in width to interstriae; interstitial setae much less numerous, all in interstitial rows (except <i>truncatus</i>)	16
7(6).	Ground setae on pronotum and elytra very short, stout, almost scalelike; very small; Brazil; 1.5–1.7 mm	<i>nanus</i> Wood
—	Setae on pronotum and elytra longer, hairlike; body larger than 2.0 mm	8
8(7).	Slender species, at least 2.2 times as long as wide; interstitial setae (at least on disc) of very fine, slender hair, not separable into ground cover and erect bristles; pronotum with numerous subasperate tubercles in anterolateral areas	9
—	Stouter than 2.0 times as long as wide; interstitial setae with uniseriate, erect setae evident at least on part of declivity; pronotum variable	10
9(8).	Pronotum surface smooth, shining between punctures; basal margins of elytra armed by a strong, single row of crenulations, with no submarginal granules (sparse granules present); interstitial vestiture of fine hair on disc, of stout, obscurely subplumose setae on declivity; Venezuela; 2.2 mm	<i>hirtellus</i> Schedl
—	Pronotum obscurely reticulate, granulate-subreticulate near base; row of crenulations on basal margins of elytra rather low, with many submarginal crenulations; interstitial setae of fine, semi-recumbent hair of variable length on disc and declivity; Brazil (Santa Catarina); 1.9 mm	<i>schedli</i> Wood
10(9).	Pronotum smooth, shining, punctures minute, abundant, irregular in distribution, ground setae hairlike; striae weakly impressed, punctures small; interstriae at least three times as wide as striae . . .	11
—	Pronotum surface varied, most setae in pronotal ground cover (when present) at least half as long as erect setae	12

- 11(10). Pronotum with median line clearly, broadly elevated, areas lateral to line shallowly impressed, densely, minutely punctured; striae punctures on basal half of disc weakly impressed, punctures very small, obscure; elytral declivity with moderately abundant, short ground setae; French Guyana; 3.8–4.0 mm *puberulus* (Chapuis)
- Pronotum normally convex on basal half, median line not marked, surface reticulate on basal fourth and other scattered areas, punctures rather coarse, moderately deep; striae rather weakly impressed, punctures on basal half of disc rather coarse, moderately impressed, on posterior half of disc and declivity very small; declivity without ground cover of short setae, all setae erect; Bolivia; 2.3 mm *ovatus* (Eggers)
- 12(10). Ground setae on declivity short, rather stout, less than one-third as long as erect setae; pronotum shining 13
- Ground setae on declivity slender, at least half as long as erect setae; median line on pronotum never impunctate; interstitial tubercles on disc smaller, closer, rather poorly formed, sometimes confused 15
- 13(12). Median line impunctate on basal half of pronotum, punctures small, close, distinct; interstitial punctures on disc not indicated, each with a row of tubercles; Bolivia; about 3.4 mm *tuberculatus* (Eggers)
- Median line on basal half of pronotum punctured, not evident, punctures small or coarse, deep; interstitial punctures on disc very small on margins, central row replaced by tubercles, tubercles slightly confused or uniseriate 14
- 14(13). Interstitial punctures on disc slightly confused; interstriae on disc slightly wider than striae; erect interstitial setae identifiable only on declivity; declivital tubercles of about equal size on all interstriae; Brazil (Santa Catarina); 1.9–2.0 mm *brasiliensis* (Schedl)
- Striae distinctly wider than interstriae, interstitial tubercles entirely uniseriate; erect interstitial setae identifiable almost to base of disc; declivital tubercles on 3, 5, 7, and 9 distinctly larger; Venezuela; 1.8 mm *hispidulus* Eggers
- 15(12). Pronotum reticulate on anterior third, punctures very close, rather coarse, their interiors smooth, shining; submarginal crenulations at bases of interstriae 2–4 smaller, narrower, each not more than half width of other interstriae; elytral declivity more narrowly convex on lower half; Peru; 2.1–2.2 mm *woytkowskii* Wood
- Pronotum reticulate to base in specimens from Colombia and minutely, sparsely punctured (Venezuelan specimens with reticulation and punctures variable on anterior three-fourths), interiors of punctures reticulate to base; submarginal crenulations at bases of interstriae 2–4 higher, wider, most more than half as wide as an interstriae; elytral declivity steeper, more broadly convex; Colombia to Venezuela; *Clusia*; 2.0–3.0 mm *collaris* Chapuis
- 16(6). Setae on pronotum and elytra stout, scalelike, each about 2–6 times as long as wide 17
- Setae on pronotum and elytra slender, hairlike 19
- 17(16). Scales on pronotum and interstriae more slender, each about 5–8 times as long as wide, those on interstriae usually pointed; declivital interstriae 1, 3, 5, 7, and 9 armed by pointed tubercles; Venezuela; *Eschweilera*; 1.5–1.7 mm *venezuelensis* (Schedl)
- Scales on pronotum and interstriae each about two to four times as long as wide; declivital tubercles present on interstriae 3–9 18
- 18(17). Declivital interstriae 1–9 each armed by a uniseriate row of minute to obsolete tubercles to their apices; striae punctures on disc unusually large; scales on pronotum and elytra blunt, each slightly longer than wide; Venezuela; *Inga*; 1.5–1.7 mm *squamiger* Wood

- Declivital interstriae 1, 3–9 and base of 2 armed by moderately large, rounded tubercles; striae punctures on disc large, normal; scales on pronotum and elytra blunt, each almost four times as long as wide; Brazil; 1.5–1.6 mm *hebes* Schedl
- 19(16). Pronotum without asperities; declivital interstriae 9 not elevated, tubercles very small 20
- Pronotum armed by several rather coarse asperities; declivital interstriae 9 elevated and rather coarsely serrate (except *argentinensis*) 21
- 20(19). Male frons shallowly concave from epistoma to upper level of eyes, lateral margins less strongly elevated, face of concavity with many rather widely spaced, moderately coarse punctures; interstitial tubercles very slightly larger; female frons punctured above level of antennal insertion; Colombia; *Inga*; 1.5–1.7 mm *ingae* Wood
- Male frons deeply concave from epistoma to upper level of eyes, lateral margins on lower half strongly, acutely elevated, face of concavity with almost no punctures except near upper margin; interstitial tubercles very slightly larger; female frons without punctures on lower two-thirds; Colombia; ex “Guamo”; 1.8–1.9 mm *simplicidens* Wood
- 21(19). Mostly larger species; striae narrower than interstriae; erect interstitial setae either confused or uniseriate, shorter than distance between rows; declivital interstriae 9 modestly to strongly elevated, moderately serrate 22
- Smaller species; striae wider than interstriae; erect interstitial setae often longer than distance between rows; declivital interstriae 9 strongly to very strongly elevated, very coarsely serrate 24
- 22(21). Male frons more strongly impressed from epistoma to upper level of eyes, lateral margins immediately above antennal insertions subacutely elevated (crest rounded, not pointed); subcircular median third from epistoma almost to level of antennal insertions coarsely rugose-reticulate; interstriae 9 feebly elevated on declivity, tubercles very small; striae setae conspicuous, half as long as those of interstriae, very fine, semirecumbent, interstitial bristles stout, closely set, slightly shorter than distance between rows; Argentina; 1.6–1.7 mm *argentinensis* (Schedl)
- Male frons much less strongly impressed on lower half, lateral margins not or weakly elevated, lower area smooth, with fine punctures; declivital interstriae rather weakly elevated, tubercles or serrations rather small; much larger species 23
- 23(22). Elytral declivity subobliquely truncate in both sexes, its base armed by a circumdeclivital ring of tubercles, interstriae 1–8 each with a large blunt spine; discal interstriae usually with vestiture abraded, short, confused when present; male frons convex, unarmed on lower half, weakly concave above; male scape with a small tuft of hair; Colombia; *Ceroxylon quindiuense*; 2.7–3.3 mm *truncatus* Wood
- Elytral declivity convex, its base rounded, not armed by a ring of spines; discal interstriae with uniseriate setae rather short; male frons subconcave from epistoma to upper level of eyes, lateral margins distinctly elevated on lower half; male scape with a small tuft of hair; Venezuela; tree bole; 3.2–3.9 mm *amplus* Wood
- 24(21). Pronotum less coarsely punctured; body stouter, 2.0 times as long as wide; interstitial tubercles on disc and declivity more closely spaced, of more uniform size; interstitial setae shorter than distance between rows; color dark brown 25
- Pronotum more coarsely punctured; body more slender, 2.1–2.2 times as long as wide; interstitial tubercles on declivity of irregular size and more widely spaced than on disc; color black 28
- 25(24). Pronotum reticulate; interstitial tubercles on declivity uniseriate, those on 1–3 very small, almost obsolete; interstitial setae shorter than distance between rows 26
- Pronotum shining; interstitial tubercles on 1–3 of declivity about equal to those on disc; interstitial setae fine, slender, each about as long as distance between rows 27

- 26(25). Male frons shallowly concave on less than lower half, upper area with a large, impunctate, brilliantly shining area on median two-thirds extending to well above eyes; pronotum shining, weakly reticulate; discal striae slightly wider than interstriae, punctures deep; erect interstitial setae rather coarse, of uniform width; Brazil (Santa Catarina); 1.2 mm *novateutonicus* (Schedl)
- Male frons broadly, rather deeply concave to slightly below upper level of eyes, surface rugose-reticulate above; pronotum dull, strongly rugose-reticulate; striae almost twice as wide as interstriae, very large punctures shallow; erect interstitial setae moderately coarse, each distinctly wider at its apex; Venezuela; *Ochroma*, *Sterculia pruriens*; 1.3–1.4 mm *vesculus* Wood
- 27a(25). Smaller species; male frons more broadly, more deeply concave to slightly above upper level of eyes; strial punctures smaller, discal interstriae less strongly convex; interstitial setae stouter, each about eight to ten times as long as wide; declivital interstriae 9 rather weakly elevated, tubercles much smaller, about as on other interstriae; Brazil (Santa Catarina); 1.4 mm *profanus* Schedl
- Larger species; male frons shallowly concave, concave area not attaining upper level of eyes; strial punctures on disc larger, discal interstriae much more strongly convex; interstitial setae slender, hairlike; declivital interstriae 9 rather strongly elevated, denticles moderately large 27b
- 27b(27a). Declivital interstriae 9 moderately elevated, much less strongly serrate; discal striae impressed, punctures much smaller, closer; declivital interstriae 1–3 small, of about equal size; Colombia; *Clusia guianensis*; 1.5–2.0 mm *nitidicolis* (Eggers)
- Discal interstriae 9 very strongly elevated, coarsely serrate; discal striae weakly impressed, punctures large, deep, as wide as interstriae; declivital interstriae 1 armed by about five rather coarse tubercles, those on 2 and 3 smaller, those near apex of 5 and 7 as large as those on 3; Brazil (Santa Catarina); 1.8 mm *erinaceus* Schedl
- 28(24). Male frons more strongly concave to above upper level of eyes; declivital interstriae 1 unarmed by fine tubercles; interstitial setae slightly longer, closer; Argentina; 2.1–2.2 mm (see also *jujuya* Blackman) *harringtoni* Blackman
- Male frontal concavity not as deep, less extensive, ending well before upper level of eyes; declivital interstriae 1 armed by several small tubercles; interstitial setae slightly shorter, less numerous 29
- 29(28). Declivital interstriae 2 and 4 armed by tubercles (usually smaller), 1, 3, and 5 often with one tubercle distinctly larger than others; interstitial setae on disc and declivity very long, about three times as long as distance between rows, equally long on pronotum; Colombia; ex “arbol de sangregao”; 1.9–2.0 mm *hirtus* Wood
- Declivital interstriae 2 and 4 unarmed by tubercles, tubercles on 3, 5, 7, and 9 larger; interstitial setae on disc and declivity up to one and one-half times as long as distance between rows; Venezuela; *Ficus*; 1.6–1.7 mm *fici* Wood
- 30(2). Surfaces of pronotum and elytra (between punctures) smooth, shining; discal crenulations on interstriae higher, more strongly acute, either broad and uniseriate or narrow and confused 31
- Surfaces of pronotum (usually) and elytra minutely reticulate or reticulate-granulate; interstriae with crenulations low, poorly formed, mostly on central one-third of each interstriae 33
- 31(30). Discal interstriae less than twice as wide as striae, interstitial setae short, erect, uniseriate from base to apex, each seta within a moderately large pit, anterior margin of this pit usually crenulate in all females and most males, these crenulations each about half as wide as interstriae, forming a uniseriate row; Colombia and Venezuela to Brazil (Sao Paulo, Santa Catarina); *Brosimum*, *Pseudoolmedia*; 2.1–2.8 mm *rudis* Eichhoff
- Discal interstriae two or three times as wide as striae, fine, short interstitial hair and small, narrow, acute interstitial crenulations strongly confused on disc 32

SCOLYTIDAE OF SOUTH AMERICA

- 32(31). Female frons without a long median sulcus, a small median fovea present slightly above level of antennal insertion, upper frons and vertex rugose-reticulate; interstriae twice as wide as striae at base, only slightly wider than striae at base of declivity, small punctures on disc not bearing a small seta, all setae on disc arising from a puncture at base of crenulations; Brazil (Santa Catarina); 2.5–2.8 mm *erosus* Schedl
- Female frons with a strong, rather broad median sulcus extending from vertex to a point slightly above level of antennal insertion; Colombia; 3.2 mm *sulcifrons* Chapuis
- 33(30). Smaller, more slender (body 1.8 times as long as wide); discal interstriae 2 and 3 with setae uniseriate to base 34
- Larger, stouter (body 1.6 times as long as wide); discal interstriae 2 and 3 with setae confused (sometimes also confused on other interstriae) at least on basal half 35
- 34(33). Elytral interstriae smooth (obscure reticulation in female), shining; pronotum reticulate, dull; discal interstriae each with a uniseriate row of transverse crenulations (each at least two-thirds as wide as an interstriae), posterior slope with a small puncture, each bristle equal in length to half distance between rows; Brazil (Santa Catarina); 2.3–2.6 mm *cylindricus* Schedl
- Both pronotum and elytral interstriae reticulate, dull; interstitial crenulations slightly narrower and higher, punctures on posterior slope larger, each bristle equal in length to slightly less than half distance between rows; Bolivia; 2.2 mm *opacicollis* Eggers
- 35(33). Interstriae with tubercles and setae confused on basal one-half of disc, uniseriate on posterior half of disc and declivity, setae fine, short, recumbent; pronotum reticulate; color black; Peru; 2.9–3.0 mm *incanus* Wood
- Interstriae with tubercles and setae confused from base to base of declivity 36
- 36(35). Discal interstriae 1–9 with erect setae confused; tubercles on upper half of declivital interstriae I confused 37
- Discal interstriae 3–9 with erect setae uniseriate; tubercles on upper half of declivital interstriae I uniseriate 39
- 37(36). Pronotum spaces between punctures on disc smooth, shining; discal striae abruptly, rather deeply impressed, punctures obscure to obsolete; interstitial setae 2–9 on disc confused, on declivity 1–4 uniseriate on at least lower two-thirds, setae shorter than distance equal to width of an interstriae, 2–7 each with a row of tubercles; Brazil (Goyas to Parana); 2.4–2.9 mm *rugulosus* Eggers
- Pronotum spaces between punctures reticulate; discal striae less strongly impressed 38
- 38(37). Declivital interstriae 2–4 with tubercles confused on more than upper half; erect interstitial setae on disc and declivity mostly pointed, longer, more slender, length of each at least equal to two-thirds width of an interstriae; Bolivia; 2.6 mm *vestitus* Eggers
- Declivital interstriae 1–4 more narrowly convex, tubercles uniseriate on at least lower three-fourths, setae shorter, slightly stouter, length of each equal to one-fourth to one-third width of an interstriae; Bolivia; 2.7 mm *suturalis* Eggers
- 39(36). Frons in both sexes smooth, densely, sharply, finely punctured from epistoma to level of antennal insertion; propleuron near posterior margin with normal sculpture; Bolivia, Peru to Mato Grosso in Brazil; 2.5–3.0 mm *uniseriatus* Eggers
- Frons in both sexes minutely rugose from epistoma to level of antennal insertion, few if any punctures indicated; propleuron near posterior margin transversely strigose; Mexico (Chapias) to Brazil; *Brosimum*; 2.4–3.4 mm *pilula* (Erichson)

- 40(1). Discal interstriae 2 and 3 (occasionally all) with setae more numerous, confused; pronotum usually with asperate crenulations small, less numerous, most in lateral areas on anterior third; striae punctures very large, interstriae half as wide as striae; ground cover on interstriae short, stout but sharply pointed, a few longer erect setae on odd-numbered interstriae; sparse erect setae about as long as distance between rows, twice as long as ground setae; declivital interstriae 1, 3, 5, 7, and 9 each armed by a sparse row of pointed tubercles; Venezuela; *Eschweilera*; 1.8–2.1 mm **tetricus Wood**
- Striae and interstriae of equal width; all discal interstriae with setae of fine, long hair, in uniseriate rows, one row on each interstriae; all interstriae armed by tubercles; asperities on pronotum usually larger, more widely distributed 41
- 41(40). Male epistomal carina transversely short, its length equal to or conspicuously shorter than width of an eye; male frons concavely impressed to upper level of eyes or above; declivital tubercles small, of about equal size on interstriae 1–5 (except absent on 2 and 4 in *minor*); elevated crest of interstriae 9 ending before joining costal margin (except in *biguttatus*) 42
- Male epistomal carina transversely rather long, its length conspicuously greater (1.5–2.0 times) than greatest width of an eye; declivital tubercles on interstriae 2 and 4 usually absent or greatly reduced in number in male, usually present in female but reduced in size and number; costa of interstriae 9 usually strongly elevated, joining costal margin (without interruption) and continuing to apex (rather weak in some *picipennis*) 45
- 42(41). Pronotum reticulate, asperities of more regular size and wider distribution; male epistomal carina much more strongly elevated; male frontal impression on upper half rather narrow, ending at upper level of eyes; Guatemala to Argentina; tree bole; 2.0–2.4 mm **subovatus Blandford**
- Basal half of pronotum mostly smooth, shining, anterior one-fourth armed by several asperities; interstitial crenulations on disc much smaller, with few impressed points; submarginal crenulations at base of elytra less numerous 43
- 43(42). Body more slender, 1.9 times as long as wide; male frons moderately, concavely impressed to slightly above upper level of eyes, surface of concavity with dense, rather obscure micropunctures; discal striae more broadly, less strongly impressed, interstriae as wide as striae on basal half of disc; asperities on anterior fourth of pronotum rather small, broad (superficially resembling *setulosus* but entirely unrelated); Colombia (Bogota); 2.2 mm **schoenbachi Kirsch**
- Body stouter, 1.7 times as long as wide; male frons more broadly, more deeply, concavely impressed to well above upper level of eyes, surface of concavity partly reticulate, especially on upper half; discal striae narrowly, more abruptly impressed, interstriae two or more times as wide as striae on basal half of disc; anterior fourth of pronotum armed by several large asperities 44
- 44(43). Discal interstriae near base three or more times as wide as striae, interstitial tubercles much smaller, each about half or less as wide as this interstriae; pronotum with disc mostly smooth (some reticulation), punctures rather small, shallow; serrations on anterior margin much larger, less numerous; interstitial setae longer, stouter; body color brown; Panama to Colombia and Venezuela; *Brosimum*; 1.8–2.7 mm **biguttatus Blandford**
- Discal interstriae near base about twice as wide as striae, interstitial tubercles much larger, each about as wide as this interstriae, much higher; pronotum disc strongly reticulate, punctures much deeper; pronotum serrations on anterior margin slightly smaller, more numerous; interstitial setae slightly shorter, more slender; body color black; Mexico (Morelos); 2.7–3.2 mm . . . **ebeneus Wood**
- 45(41). Body size small, 1.3–2.0 mm; declivital interstriae 9 less strongly elevated; punctures on disc of pronotum rather coarse, moderately deep 46
- Body size larger, 2.0–3.0 mm; declivital interstriae 9 more strongly elevated; punctures on disc of pronotum small to obsolete (some exceptions in *setulosus*) 49

SCOLYTIDAE OF SOUTH AMERICA

- 46(45). Declivital tubercles and setae usually present on interstriae 2 and 4 (although often reduced in size and number); punctures on disc of pronotum coarse, deep; body form more slender, 2.1 times as long as wide 47
- Declivital tubercles and setae absent on lower two-thirds of interstriae 2 and 4; punctures on disc of pronotum less numerous, not as deep; body form stout, about 1.8 times as long as wide 48
- 47(46). Punctures on pronotum disc moderately large, deep; striae slightly narrower than interstriae, interstitial crenulations very coarse; male frontal concavity appearing slightly narrower, ending above rather abruptly well below upper level of eyes; Bolivia (Cochabamba); 1.7 mm *asperulus* Eggers
- Punctures on pronotum disc very coarse, deep; striae distinctly wider than interstriae, interstitial crenulations moderately large; male frontal concavity apparently wider, declining more gradually above, attaining upper level of eyes; Chile to Peru; *Ficus carica*; 1.8–2.0 mm *willei* Schedl
- 48(46). Pronotum disc at least partly reticulate; discal interstriae less strongly convex; setae on elytral interstriae shorter, slightly stouter; Brazil (Amazonas); 1.3 mm *contortus* Schedl
- Pronotum without any reticulation on disc; discal interstriae more strongly convex; setae on elytral interstriae more slender, slightly longer; Colombia; *Pseudoolmedia*; 1.3–1.4 mm *minor* Wood
- 49(45). Declivital interstriae 9 rather weakly elevated (half or less as high as wide, 2, 4, 6, and 8 in both sexes armed by fine tubercles to their apices; S Brazil to Bolivia; 1.8–2.5 mm *picipennis* Eggers
- Declivital interstriae 9 very strongly, narrowly elevated, its summit rather strongly serrate; sexually dimorphic, all or most of interstriae 2, 4, 6, and 8 often devoid of tubercles in male, tubercles usually present in female 50
- 50(49). Color all or mostly black; pronotum strongly, uniformly reticulate, asperities shining; Colombia; *Quercus humboldtii*; 2.4–3.0 mm *remorsus* Wood
- Color brown (except black in *serratus*), pronotum usually darker; pronotum shining, rarely with weak reticulation in isolated areas 51
- 51(50). Male declivity with tubercles on interstriae 2 and 4 more widely spaced but continued to apex, discal striae moderately impressed to base, much more strongly impressed at base of declivity, moderately, narrowly impressed on declivity; tuft of setae on male scape sparse, consisting of about a dozen long hairs (female not seen); Bolivia; 2.2 mm *serratus* Eggers
- Male declivity with tubercles on interstriae 2 and 4 absent; striae on disc and declivity weakly to moderately impressed; male scape ornamented by a large tuft of several dozen long setae 52
- 52(51). Discal interstriae less strongly convex (somewhat flattened), their crenulations wider, not as high; punctures on disc of pronotum mostly smaller, not as deep; scutellum about twice as wide as long, less strongly convex; Colombia to Venezuela; ex unidentified trees; 2.1–2.7 mm *transversus* Chapuis
- Discal interstriae more strongly convex, their crenulations narrower, higher; punctures on disc of pronotum mostly larger, deeper; scutellum only slightly wider than long, much more strongly convex; Mexico (Jalisco) to Brazil; *Brosimum*, *Cedrela mexicana*, *Celtus*, *Croton*, *Ficus*, 1.9–2.4 mm *setulosus* Eichhoff

Phloeotribus hylurgulus Schedl

Phloeotribus hylurgulus Schedl, 1959:405. Holotype, sex?; Huaraz, Peru; deposited in Frey Museum, now in NHMBS, Basel (References in Wood & Bright c1992:222)

Diagnosis: Distinguished from *pilifer* Wood and *hirticulus* Wood by the larger size; by the coarsely, deeply punctured pronotum with no asperities; by the absence of tubercles on declivital interstriae 1 and 2; and by the moderate elevation and strong serration of 3 and 9; and by other characters described below.

Male: Length 3.0–3.1 mm, 2.3 times as long as wide; color dark brown. Frons broadly, rather deeply concave from epistoma to very slightly above upper level of eyes; a weak, irregular, transverse elevation at middle of concavity; lateral margins armed by a moderate, sharply pointed denticle at level of antennal insertions; surface shining, mostly smooth and not clearly punctured on lower half of concavity, lateral and upper margins rather coarsely, closely punctured above; vestiture of fine, long, moderately abundant hair; antennal scape ornamented by fewer than a dozen setae. Pronotum 0.80 times as long as wide; widest at base; surface rather coarsely, deeply, irregularly punctured, middle third of median line shining, impunctate, weakly elevated; vestiture of fine, moderately long, rather abundant hair. Elytra 1.6 times as long as wide, 2.1 times as long as pronotum; crenulations on basal margins rather coarse, about 4 submarginal crenulations on each elytron; striae 1 weakly, others feebly impressed, punctures rather coarse, deep; interstriae almost twice as wide as striae, shining, punctures small, uniseriate (a few of them weakly crenulate on anterior margin). Declivity moderately impressed between left and right interstriae 3; interstriae 1 and 2 smooth, shining, impunctate, 3 rather strongly elevated on upper two-thirds, crest rather finely serrate, 5 and 7 more weakly elevated, each armed by two or more small denticles, 9 more strongly, narrowly elevated and more coarsely dentate. Strial and interstitial setae hairlike, fine, long on disc and sides, subglabrous on declivity.

Female: Similar to male except frons convex, sculpture simple (lateral denticles absent); elytral declivity similar except elevations and impressions much weaker, interstriae 1 with a row of fine, rounded tubercles.

Distribution: Peru: Huaraz [Huaraz Prov.], VII-1954, H. Loeffler.

Notes: The above treatment was based on 1 male paratype and 1 female paratype in the NHMW, Wien.

Phloeotribus pilifer Wood, n. sp.

Phloeotribus pilifer Wood: Holotype ♂; Andes Highland Lakes, Shishma, Hunuco, Peru, 3600–4000 m; USNM, Washington, designated below

Diagnosis: Lateral margins of male frons at level of antennal insertion armed by a pair of sharply pointed tubercles; distinguished from *hirticulus* Wood by the less deeply, less extensively concave male frons.

Male: Similar to female except frons rather strongly, broadly concave from epistoma to upper level of eyes, lateral margins acutely elevated from epistoma to just below upper level of eyes, crest armed at lower level of antennal insertion by a moderately large, acutely pointed tubercle; concave area reticulate, upper one-fourth armed by several granules, vestiture of sparse, rather short hair; pronotal asperities averaging smaller.

Female: Length 2.2–2.5 mm, 2.1 times as long as wide; color brown. Frons convex above level of antennal insertion, moderately, transversely impressed below; surface reticulate, rather coarsely, shallowly, obscurely punctured; vestiture of sparse, fine hair; middle segment of antennal club about 6 times as wide as long. Pronotum 0.80 times as long as wide; anterolateral areas armed by about 2 coarse and several small asperities; widest at base, sides arcuately converging cephalad; surface smooth, shining, irregular, punctures small, moderately abundant, distinctly impressed; vestiture of fine, long to very long hair. Elytra 1.4 times as long as wide, 2.1 times as long as pronotum; bases of interstriae 2–5 with a total of about five submarginal crenulations; striae rather weakly impressed, stronger toward declivity, punctures coarse, deep; interstriae as wide as striae, smooth, shining, crenulations somewhat irregularly crenulate, narrow, rather coarse, close. Declivity convex, steep; striae and interstriae narrower than on disc; each interstriae armed by a row of small, pointed tubercles, except rather coarse on 9; costal margin near apex sometimes with a few serrations; vestiture of fine, long interstitial hair, longest setae equal to combined width of two interstriae plus two striae.

Distribution: Peru (Huanuco).

Type material: The male holotype, female allotype, and 5 paratypes were taken at Shishmay, Dep. Huanuco, Peru, Andes Highland Lakes, 3600–4100 m, 15-20-IX-1937, No. 3787, F. Woytkowski. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Phloeotribus hirticulus Wood, n. sp.

Plate XIII

Phloeotribus hirticulus Wood: Holotype ♂; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington, designated below

Diagnosis: Lateral margins of male frons armed at level of antennal insertion by a pair of sharply pointed tubercles; distinguished from *pilifer* Wood by the much more deeply concave male frons; and by the slightly shorter interstitial setae.

Male: Similar to female *pilifer* except frons much more deeply, extensively concave to well above upper level of eyes, granules on upper fourth of concavity minute to obsolete, very sparse; other characters as in female.

Female: Length 2.1–2.5 mm, 2.1 times as long as wide; color brown. As in *pilifer* except pronotal crenulations smaller; interstitial crenulations smaller, narrower,

interstitial setae shorter; longest equal to combined width of one interstriae plus one striae.

Distribution: Venezuela (Merida).

Type material: The male holotype, female allotype, and 70 paratypes were taken at La Carbonera Experimental Forest 50 km airline NW Merida, Merida, 14-X-1969, 2500 m, No. 52, ex unidentified liana, SLW. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Phloeotribus nanus Wood

Phloeotribus nanus Wood, 1974:8. Holotype ♂; 260 km N Xavantina, Mato Grosso, Brazil; BMNH, London (References in Wood & Bright c1992:225)

Diagnosis: Interstriae twice as wide as striae, setae numerous, confused, stout, almost scalelike.

Male: Similar to female except frons broadly, moderately concave from epistoma to upper level of eyes, concavity covered by short, moderately stout setae.

Female: Length 1.5–1.7 mm, 1.8 times as long as wide; color yellowish brown, vestiture pale. Frons convex, reticulate, with fine granules on upper two-thirds; vestiture of fine, short, inconspicuous hair. Pronotum 0.84 times as long as wide; widest at base, sides arcuately convergent cephalad; anterolateral areas armed by several asperities; surface smooth, shining, punctures rather small, very close; vestiture of abundant, short, stout, almost scalelike setae, each about 6 times as long as wide; Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; bases of interstriae 2–5 armed by a total of about seven submarginal crenulations; striae distinctly impressed, punctures moderately large, partly confluent, not clearly evident; interstriae almost twice as wide as striae, convex, surface smooth, shining, punctures small, numerous, confused; each interstriae with a central row of small granules. Declivity convex, steep, about as on disc; vestiture of abundant, confused, short, stout, pointed setae, each about six times as long as wide, each interstriae with a central row of erect setae (each about one and one-half times as long as ground setae), each about one-third as long as distance between rows.

Distribution: Brazil: 260 km N Xavantina, Mato Grosso, 12°49'S, 51°46'W, 1-XI-1-XII-1968, R.A. Beaver.

Notes: The above treatment was based on the type series of 10 specimens.

Phloeotribus hirtellus Schedl

Phloeotribus hirtellus Schedl, 1966:99. Holotype ♀; Venezuela; NHMW, Wien (References in Wood & Bright c1992:222)

Diagnosis: Distinguished by the near absence of tubercles on the pronotum; by the thoroughly confused interstitial setae on disc and declivity; and by the fine, hairlike setae on pronotum and elytral disc, slightly subplumose on declivity.

Female: Length 2.2 mm, 2.24 times as long as wide; color almost black. Frons irregularly convex from epis-

toma to vertex, weak transverse impressions just above epistoma and slightly above level of antennal insertion; surface rugose-reticulate, punctures moderately close and rather coarse on upper half, obscure below; vestiture of moderately abundant, fine, rather long hair. Pronotum 0.92 times as long as wide; unarmed, except lateral areas with several rounded granules (no true asperities); surface smooth, shining, punctures rather small, close, mostly spaced by less than half diameter of a puncture; vestiture of very fine, erect, rather long hair of moderate abundance. Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; bases armed by a row of rather coarse crenulations, submarginal crenulations almost absent; striae moderately impressed, punctures rather coarse, deep; interstriae slightly wider than striae, almost smooth, shining, with rather numerous fine, confused punctures, a central row of small tubercles extending almost to base. Declivity broadly convex, steep; striae narrower and deeper than on disc, interstriae narrower, tubercles obsolete. Vestiture on disc of fine, confused, rather abundant, moderately long hair of about equal length, on declivity similar but stouter, obscurely, weakly plumose, distinctly shorter.

Distribution: Venezuela: "Venezuela."

Notes: The above treatment was based on the female holotype.

Phloeotribus schedli Wood, n. sp.

Phloeotribus schedli Wood: Holotype ♀; Nova Teutonia, Santa Catarina, Brazil, 27°11'B, 52°32'L, 300–500 m; NHMW, Wien, designated below

Diagnosis: Distinguished from *hirtellus* Schedl by the smaller size; by the reticulate pronotum with larger crenulations in lateral areas; by the confused tubercles on the discal interstriae; and by the fine declivital hair.

Female: Length 1.9 mm, 2.2 times as long as wide; color black. Frons similar to female *hirtellus* except surface finely rugose-reticulate, a few small, obscure punctures above. Pronotum 0.86 times as long as wide; surface rugose-reticulate, obscure punctures on median third, lateral areas on posterior two-thirds granulate (subreticulate), distinct crenulations at or near lateral margins; vestiture of fine, moderately abundant, short hair. Elytra 1.6 times as long as wide, 2.3 times as long as pronotum; crenulations at basal margins small, submarginal crenulations on interstriae 1–5 numerous, moderately coarse; striae 1 and 4–9 weakly impressed, 2 and 3 not impressed, 1–3 obscure near base, punctures small, distinct; interstriae about twice as wide as striae, surface shining, punctures not clearly evident, moderately coarse tubercles close, confused on basal half of disc, becoming uniseriate before base of declivity. Declivity occupying posterior third; rather narrowly convex, moderately steep; striae more strongly impressed, interstriae mostly smooth, shining, each interstriae with a uniseriate row of small, rounded tubercles, those in

lateral areas pointed. Vestiture confused, of fine, moderately long, hairlike setae, some of those arising from tubercles distinctly longer.

Distribution: Brazil (Santa Catarina).

Type material: The female holotype was taken at Nova Teutonia, Santa Catarina, Brazil, 27°11'B, 52°32'L, XI-1968, 300–500 m, F. Plaumann. The holotype is in the NHMW, Wien.

Notes: The female holotype (antennae missing) was removed from the Schedl series of paratypes of *Phloeotribus profanus* Schedl, an unrelated species.

Phloeotribus puberulus (Chapuis)

Phloeotribus puberulus (Chapuis), 1869:46 (*Dryotomus*). Holotype ♀; Cayenne [French Guyane]; IRSNB, Brussels (References in Wood & Bright c1992:227)

Diagnosis: Distinguished from other members of the genus by the large size; by the absence of asperities on the pronotum; by the rather abundant hairlike ground vestiture on the elytra; and by the sparse, uniseriate, hairlike interstitial setae.

Female: Length 3.8–4.0 mm, about 1.9 times as long as wide; color black. Frons convex from level of antennal insertion to vertex, a moderate transverse impression above epistoma; a median fovea at center of frons; surface reticulate below fovea, rugose-reticulate above; vestiture of sparse, short, inconspicuous, hairlike setae; antennal scape long, slender, club sublamellate, segments each about 6 times as wide as long. Pronotum 0.88 times as long as wide; devoid of asperities, surface shining, with dense, minute punctures on median half, punctures numerous but of irregular distribution in lateral areas; median line on most of basal half distinctly (not sharply) elevated, lateral areas slightly impressed near median elevation. Elytra about 1.3 times as long as wide, 1.7 times as long as pronotum; basal margins of elytra weakly elevated, serrations poorly formed, almost a continuous costa; striae feebly impressed, punctures small, shallow; interstriae at least twice as wide as striae, smooth, brightly shining, feebly convex, punctures for ground vestiture very small, confused, moderately abundant on 1 and 2, sparse laterally, punctures giving rise to erect setae larger, sparse, uniseriate. Declivity rather steep, broadly convex; striae more deeply impressed, interstriae more strongly convex except 2 weakly impressed; interstitial punctures abundant, confused, on all interstriae, minute granules sometimes present at bases of erect setae. Vestiture of ground cover of very short setae, these more nearly hairlike on disc, more nearly scalelike on declivity (all scales 3 or more times longer than wide). Protibia with 5 socketed teeth on lateral margin.

Distribution: French Guyane: "Cayenne, Dejean."

Notes: The above treatment was based on the female holotype. This specimen is slightly crushed, with 1 elytron ajar; for this reason most measurements used above are approximations. Bright & Skidmore (1997:490) report

this species from Brazil; these specimens were not seen by me.

Phloeotribus ovatus (Eggers)

Phloeotribus ovatus (Eggers), 1943:347 (*Dryotomus*). Holotype ♂; Bolivia (Cochabamba); USNM, Washington (References in Wood & Bright c1992:225)

Diagnosis: Distinguished from *puberulus* (Chapuis) by the normally convex posterior half of pronotum, with median line not marked; by the discal striae being weakly impressed, punctures moderately coarse on basal half, very fine behind and on declivity; and by the absence of ground setae on the declivity.

Male: Length 2.3 mm, 1.8 times as long as wide; color black. Frons moderately concave to upper level of eyes; lateral margins obtusely elevated from level of antennal insertion half distance to upper level of eyes, subacutely elevated below, without a denticle; surface of concave area half obscured by glue, obscurely reticulate, punctures sparse, small, shallow, hairlike setae sparse, inconspicuous; antennal club with segments each about 4 times as wide as long. Pronotum 0.81 times as long as wide; anterior third armed by small asperities, especially on median one-third; surface of basal one-third reticulate, smooth with obscure areas of reticulation elsewhere, rather coarsely, moderately punctured; vestiture sparse, hairlike. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; striae rather weakly impressed, punctures much coarser, deeper on basal half of disc, less than one-third as large at base of declivity; interstriae smooth, shining, several submarginal crenulations at base, each with small, moderately confused tubercles, punctures not evident. Declivity broadly convex, steep; striae narrowly, more deeply impressed, each interstriae with a row of fine tubercles, those on 3 slightly confused, no interstitial punctures. Vestiture of rather sparse, erect, slender bristles, each apparently equal in length to two-thirds width of an interstriae.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the male holotype.

Phloeotribus tuberculatus (Eggers)

Phloeotribus tuberculatus (Eggers), 1943:348 (*Dryotomus*). Holotype ♂?; Cochabamba; Bolivia; USNM, Washington (References in Wood & Bright c1992:235)

Diagnosis: Distinguished from *collaris* Chapuis by the much shorter declivital ground vestiture; by the shining, impunctate median line on basal half of the pronotum, the pronotal punctures smaller, deeper.

Male (?): Length about 3.4 mm (crushed), about 1.8 times as long as wide; color almost black. Head lost from type. Pronotum 0.85 times as long as wide; anterior half with many granules or very small asperities, surfaces smooth, shining, punctures on posterior half small,

deep, close; median line on middle half smooth, impunctate; vestiture of short, fine, recumbent hair; several rather long, coarse hairs on lateral and anterior margins. Elytra about 1.6 times as long as pronotum (crushed); basal margins modestly elevated into a continuous costa, individual crenulations obscure; striae moderately, not abruptly impressed, punctures moderately coarse, impressed; interstriae about twice as wide as striae, surface smooth, shining, punctures not indicated, each with a uniseriate row of moderately coarse tubercles (rounded toward base, pointed near declivity). Declivity broadly convex, steep; striae more narrowly, more deeply impressed; interstriae 1–3 more strongly convex, all interstriae with numerous, fine punctures, tubercles (except at base) virtually absent, minute tubercles irregularly, sparsely scattered, especially on 3; interstriae 9 somewhat costate, weakly serrate to its apex; costal margin distinctly elevated, costal margin and 9 close but not fused. Vestiture of moderately abundant, stout, short, pointed setae each equal to less than one-third length of erect setae, and uniseriate rows of erect, slender bristles, longest equal to distance between rows.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the crushed holotype, with head missing, which is thought to be a male.

Phloeotribus brasiliensis (Schedl)

Phloeotribus brasiliensis (Schedl), 1951:85 (*Phthorophloeus*). Holotype ♀; Cachoeirinha-Una, Bahia, Brazil; NHMW, Wien (References in Wood & Bright c1992:219)

Diagnosis: Distinguished from *hispidulus* Eggers by the slightly confused punctures on the discal interstriae; by the discal interstriae being only slightly wider than the striae; and by the erect interstitial setae being in identifiable rows only on the declivity.

Female: Length 1.9–2.0 mm, 1.9 times as long as wide; color very dark brown. Frons broadly convex from epistoma to upper level of eyes, surface weakly reticulate, punctures small, obscure; a conspicuous central fovea present; vestiture of fine, rather sparse hair of moderate length, uniformly distributed. Pronotum 0.80 times as long as wide; surface shining, punctures rather small, moderately deep, close; anterolateral areas with a few small crenulations; vestiture almost hairlike, moderately abundant, rather short. Elytra about 1.4 times as long as wide, 1.9 times as long as pronotum; basal row of crenulations moderately coarse, submarginal crenulations obscure to absent; striae distinctly impressed, punctures rather coarse, deep; interstriae very slightly wider than striae, surface smooth, shining, each with a row of rather closely set, small tubercles, a row of very small punctures along each margin (several of them very slightly tuberculate). Declivity broadly convex, rather steep; striae and interstriae narrower than on disc, sculpture similar. Vestiture of stout setae, ground setae half to two-thirds as long as erect setae; erect rows

clearly evident on declivity and posterior disc, not evident anteriorly; erect setae two-thirds as long as distance between rows on declivity, much shorter on disc.

Distribution: Brazil: Cachoeirinha-Una, Bahia; Nova Teutonia, Santa Catarina, V-1947, F. Plaumann.

Notes: The above treatment was based on the female holotype and on 1 other female, both from Brazil.

Phloeotribus hispidulus Eggers

Phloeotribus hispidulus Eggers, 1934:78. Holotype, sex[?]; Venezuela; Hamburg Museum, lost. Neotype ♂; Venezuela, designated by Schedl (1979:118) from 1 of 2 Eggers cotypes in NHMW, Wien (References in Wood & Bright c1992:222)

Diagnosis: Distinguished from *brasiliensis* (Schedl) by the uniseriate interstitial punctures on the disc; by the discal striae being wider than the interstriae; and by rows of erect interstitial setae being identifiable almost to the base.

Female: Length 1.8 mm, 1.8 times as long as wide; color dark reddish brown. Frons essentially flat on lower half, broadly convex above, a conspicuous fovea at center; surface reticulate from epistoma to vertex, punctures small obscure, of moderate abundance above; vestiture sparse, short, apparently mostly abraded. Pronotum 0.91 times as long as wide; surface shining, punctures on disc coarse, close, smaller toward anterior and lateral margins, several small asperities at lateral margin. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; crenulations on basal margins close, interstriae 2 with two submarginal crenulations; striae weakly impressed, punctures very coarse, deep, interstriae half to two-thirds as wide as a striae, smooth, shining, a few minute punctures at or near margins (sometimes weakly tuberculate) and uniseriate rows of interstitial tubercles, tubercles on 3, 5, 7, and 9 moderately coarse on declivity, obsolete on even-numbered declivital interstriae. Declivity broadly convex, steep. Vestiture of ground setae sparse on disc, rather abundant on declivity, each moderately stout, mostly, sharply pointed at their apex, about half as long as erect setae; erect setae slender, in rows on odd-numbered interstriae on posterior two-thirds of disc and on declivity.

Distribution: Venezuela: "Eing 1925, No. 10"; Dr. Moritz 1858 [presumably Colonia Tovar at or near his home].

Notes: The above treatment was based on 1 female cotype and on the Moritz female that Eggers had compared to the type prior to its destruction.

Phloeotribus woytkowskii Wood, n. sp.

Phloeotribus woytkowskii Wood: Holotype ♀; Cuachapayas, Dep. Amazonas, Peru, Andes, 2000 m; USNM, Washington, designated below

Diagnosis: Frons simple; interstitial setae more numerous, confused; pronotum reticulate on anterior third only.

Female: Length 2.1–2.2 mm, 2.3 times as long as wide; color very dark brown, pronotum black. Frons convex,

reticulate and rather coarsely punctured above level of antennal insertion, almost smooth and more finely punctured below; vestiture fine, short, hairlike, inconspicuous; middle segment of antennal club 4 times as wide as long. Pronotum 0.92 times as long as wide; basal margin almost straight; sides arcuately converging from base; surface without crenulations, some fine rugosity near lateral margins; reticulate on anterior third, smooth behind; posterior two-thirds coarsely punctured, centers of punctures smooth, shining, interspaces narrow, equal in width to less than one-third of a puncture, punctures smaller on anterior third; vestiture of fine, moderately long, recumbent hair. Elytra 1.6 times as long as wide, 1.9 times as long as pronotum; about twelve to eighteen submarginal crenulations at bases of interstriae 2–5; striae narrowly, rather deeply impressed, punctures small, deep, distinct; interstriae twice as wide as striae, closely set, with small, confused crenulations; vestiture of erect, confused bristles of about equal length, each about equal in length to width of an interstriae. Declivity convex, steep, somewhat narrowly rounded behind; all interstriae moderately convex and armed by uniseriate rows of irregular, pointed tubercles; vestiture confused as on disc, slightly shorter.

Distribution: Peru (Amazonas).

Type material: The female holotype and 1 female paratype were taken at Chachapoyas, Dep. Amazonas, Andes, Peru, 2000 m, 10-IX-1936, No. 3675, F. Woytkowski. The holotype and paratype are in the U.S. National Museum, Washington.

Phloeotribus collaris Chapuis

Plate XII

Phloeotribus collaris Chapuis, 1869:46. Holotype ♀; Nouvelle Grenada; IRSNB, Brussels (References in Wood & Bright c1992:219)

Phloeotribus despectus Schedl, 1966:98. Holotype ♀; Venezuela; NHMW, Wien (References in Wood & Bright c1992:221). *New synonymy*

Diagnosis: Distinguished from *woytkowskii* Wood by the simple frons; by the interstitial setae being more numerous, confused; and by the pronotum being reticulate to its base.

Male: Similar to female except frons moderately concave on upper one-third, impression not as strong below, continued as a broad, slightly concave sulcus to epistoma; surface reticulate, a few minute punctures; lateral margins (above) near eye with several coarse bristles; erect interstitial bristles continue to base on all interstriae.

Female: Length 2.0–3.0 mm, 2.0 times as long as wide; color black. Frons convex and rugose-reticulate on upper third, a few obscure punctures in marginal areas; area below level of antennal insertion almost flat, almost smooth, closely, finely, rather deeply punctured; inconspicuous vestiture of sparse, fine, hairlike setae of moderate length; middle antennal club segment 4 times as wide as long. Pronotum 0.89 times as long as wide; widest at base, sides rather weakly arcuate, converging slightly cephalad; unarmed by asperities; surface reticulate,

basal one-sixth rather coarsely, closely punctured on mesal half, anterior one-third rather finely, less closely punctured, remaining area obscurely, finely punctured, usually finely subgranular, dull; vestiture of fine hair, rather short on mesal area, longer laterally, a few rather coarse bristles in anterolateral area. Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; several coarse, submarginal crenulations at bases of interstriae 2–4; striae distinctly, rather narrowly impressed, punctures distinct, partly confluent; interstriae about twice as wide as striae, shining, a few minute punctures present, crenulations almost uniseriate, of irregular size and position, some two-thirds as wide as an interstriae on basal half of disc, one-fourth as wide near declivity. Declivity convex, steep; interstriae narrower than on disc, tubercles uniseriate, pointed, becoming almost obsolete on 2, 4, and 6; vestiture of fine, rather short, confused hair on disc, stout on declivity, odd-numbered interstriae with a few erect bristles on posterior half.

Distribution: Colombia to Venezuela.

Colombia: Nouvelle Grenada; Piedras Blancas 10 km E Medellin, Antioquia, 15-VII-1970, 2500 m, No. 681, *Clusia*, SLW.

Venezuela: “Venezuela” (type of *despectus*); Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 416, Guttiferae, SLW; Merida, Merida, 22-IX-1969, 1700 m, No. 9, *Clusia*, SLW; La Carbonera Experimental Forest, 50 km airline NW Merida, Merida, 14-X-1969, 2500 m, No. 50, 51 (also No. 92 on 27-X-1969), *Clusia*, SLW.

Biology: Taken from phloem in broken limbs 4–20 cm in diameter.

Notes: The above treatment was based on the female holotype of *collaris* Chapuis, on the female holotype of *despectus* Schedl, and on 41 other specimens from Colombia and 94 from Venezuela. I compared 3 of these females directly to the holotype of *collaris*.

Phloeotribus venezuelensis (Schedl)

Plate XVII

Phloeotribus venezuelensis (Schedl), 1936:105 (*Phloeophthorus*). Holotype ♀; Venezuela; NHMW, Wien (References in Wood & Bright c1992:235)

Diagnosis: Distinguished from *squamiger* by the more slender striae and interstitial scales; and by the absence of tubercles on declivital interstriae 1, 2, 4, 6, and 8.

Female: Length 1.5–1.7 mm, 2.0 times as long as wide; color dark brown, setae pale. Frons convex from epistoma to vertex; surface reticulate, punctures coarse, close, rather deep; vestiture of sparse, inconspicuous hair; antennal club with middle segment about 2–3 times as wide as long. Pronotum 0.83 times as long as wide; asperities absent; outline as in *nanus*; surface reticulate, punctures coarse, close, interspaces between punctures equal to less than one-fourth diameter of a puncture; vestiture moderately abundant, of stout setae of moderate length, each about 6–8 times as long as wide. Elytra 1.3 times as long as wide, 1.9 times as long as pronotum;

bases of interstriae 2–4 without submarginal crenulations; striae not impressed, punctures very large, deep; interstriae about half as wide as striae, shining, each with a uniseriate row of small, pointed tubercles. Declivity convex, steep; striae narrower than on disc; interstriae 2, 4, 5, and 8 unarmed, 1, 3, 5, 7, and 9 each armed by a row of small, pointed tubercles; vestiture in uniseriate rows on disc, in double rows on most declivital interstriae, each seta stout, its apex pointed, about six times as long as wide; without any erect bristles.

Distribution: Venezuela: Merida, Merida, 22-IX-1969, No. 15, unidentified tree, SLW; La Carbonera Experimental Forest 50 km NW Merida, Merida, 14-X-1969 (and 12-I-1970, No. 234), 2500 m, *Eschweilera*, SLW.

Biology: Taken from the bole of standing, injured trees.

Notes: The above treatment was based on 40 females, 3 of which I compared directly to the female holotype.

Phloeotribus squamiger Wood

Plate XV

Phloeotribus squamiger Wood, 1977:392. Holotype ♂; Colonia Tovar, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:234)

Diagnosis: Distinguished from *venezuelensis* (Schedl) by the stouter interstitial scales; and by the presence of tubercles on declivital interstriae 1–9.

Male: Similar to female except frons broadly concave from epistoma to upper level of eyes, its surface rugose-reticulate, setae short, stout, moderately abundant.

Female: Length 1.5–1.7 mm, 2.0 times as long as wide; color black, setae pale. Frons convex; surface rugose-reticulate, punctures minute, obscure, vestiture sparse, short, stout; middle segment of antennal club about 6 times as wide as long. Pronotum 0.89 times as long as wide; outline as in *nanus* Wood; surface shining, punctures very close, rather small, shallow; vestiture rather abundant, of short scales, each about 3–4 times as long as wide. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; as in *venezuelensis* except interstitial tubercles minute to obsolete on all interstriae; interstitial scales uniseriate on disc and declivity, each broad, about one and one-half times as long as wide.

Distribution: Venezuela: Colonia Tovar, Aragua, 4-V-1970, 1700 m, No. 495a, *Inga*, SLW; La Carbonera Experimental Forest, 50 km airline NW Merida, Merida, 27-X-1969, 2500 m, No. 89, tree seedling, SLW.

Biology: Taken from phloem tissues of broken limbs.

Notes: The above treatment was based on the type series of 36 specimens.

Phloeotribus hebes Schedl

Plate XII

Phloeotribus hebes Schedl, 1978:294. Holotype ♀; Encruzilhada, Brazil; NHMW, Wien (References in Wood & Bright c1992:222)

Diagnosis: Distinguished from *squamiger* Wood by the absence of tubercles on the lower two-thirds of declivital interstriae 2; and by the smaller strial punctures.

Male: Similar to female except frons rather deeply concave from epistoma to just below upper level of eyes, slightly narrower than in allied species; lower two-thirds of declivital interstriae 2 unarmed by tubercles.

Female: Length 1.5–1.6 mm, 2.1 times as long as wide; color very dark brown, setae pale. Frons transversely impressed from epistoma to level of antennal insertion, broadly convex above; surface reticulate, punctures small, not deep, somewhat obscure; vestiture short, rather stout, of moderate abundance; middle segment of antennal club about 6 times as wide as long. Pronotum 0.86 times as long as wide; outline as in *nanus* Wood; surface shining, punctures moderately large, close, spaces between punctures with moderately numerous impressed points; vestiture of short, stout, almost scalelike setae, each about 4 times as long as wide, and on discal area intermixed with equally long, slender bristles. Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; bases of interstriae 2–4 armed by a total of about six submarginal crenulations; striae not impressed, punctures coarse (not as large as in *squamiger*), deep; interstriae slightly narrower than striae, shining, each with a uniseriate row of setiferous granules, each granule about two-thirds as wide as an interstriae. Declivity convex, steep; striae and interstriae narrower than on disc; each interstriae armed by tubercles to apex similar to those on disc; vestiture of uniseriate rows of erect scales, each scale about four times as long as wide, almost half as long as distance between rows.

Distribution: Brazil: Cepec, Ilheus, Bahia, II-III-1981, blacklight, Kaston; Encruzilhada, Bahia, XI-1972, 980 m, M. Alvarenga.

Notes: The above treatment was based on the female holotype, on 1 female paratype, and on 19 other specimens from Brazil. Schedl had the sexes reversed in this species.

Phloeotribus ingae Wood

Phloeotribus ingae Wood, 1977:389. Holotype ♂; Buga, Colombia; USNM, Washington (References in Wood & Bright c1992:223)

Diagnosis: Distinguished from *nitidicollis* (Eggers) by the smooth, shining pronotum (between punctures); by the stouter body; and by the weakly impressed striae.

Male: Similar to female except frons broadly, rather shallowly concave from epistoma to upper level of eyes; interstitial bristles distinctly coarser.

Female: Length 1.5–1.7 mm, 2.0 times as long as wide; color dark brown. Frons transversely impressed from epistoma to level of antennal insertion, convex above; upper area smooth, slightly shagreened, punctures moderately large, shallow, not close; vestiture of sparse, short, fine, inconspicuous hair; middle segment of antennal club about 4 times as wide as long. Pronotum 0.80 times as long as wide; anterolateral areas rugose (subasperate), without asperities; surface smooth, slightly shagreened, punctures moderately coarse, rather deep, not close, spaced by distances equal to 1–3 diameters of

a puncture; vestiture of moderately abundant, fine hair of moderate length. Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; no submarginal crenulations at bases of interstriae 2–5; striae not impressed, punctures coarse, rather deep; interstriae slightly wider than striae, surface smooth, slightly shagreened, each with a central, uniseriate row of small, setiferous tubercles. Declivity convex, steep; striae and interstriae slightly narrower than on disc, sculpture as on disc; interstriae 9 not elevated, its tubercles very slightly larger than others; fine strial setae conspicuous, interstitial setae erect, as long as distance between rows, spaced within a row by similar distances.

Distribution: Colombia: Buga, Valle del Cauca, 16-V-1973, 1700 m, *Inga* pods, G. Ekis.

Biology: Breeds in fruiting pods of the host.

Notes: The above treatment was based on the type series of 104 specimens.

Phloeotribus simplicidens Wood

Phloeotribus simplicidens Wood, 1977:389. Holotype ♂; Finca La Hermosa, Salento, Caldas, Colombia; USNM, Washington (References in Wood & Bright c1992:233)

Diagnosis: Pronotum without asperities; elytral surfaces slightly shagreened; male frons strongly concave, its lateral margins on lower half acutely elevated.

Female: Length 1.8–1.9 mm, 2.1 times as long as wide; color brown.

Frons about as in *ingae* Wood except punctures on upper areas feebly granulate; middle segment of antennal club about 4 times as wide as long. Pronotum 0.91 times as long as wide; as in *ingae*. Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; about as in *ingae* except strial punctures slightly larger, vestiture slightly finer and shorter.

Male: Similar to female except frons very deeply concave from epistoma to well above upper level of eyes (much deeper and more extensive than in *ingae*, its lateral margins higher, more acutely elevated).

Distribution: Colombia: La Hermosa, Salento, Caldas, 1-VI-1959, ex guamo, J.A. Garzon.

Notes: The above treatment was based on the type series of 10 specimens.

Phloeotribus argentinensis (Schedl)

Phloeotribus argentinensis Schedl, 1952:447 (*Phthorophloeus*). Lectotype ♂; Santa Maria, Concepcion, Misiones, Argentina; NHMW, Wien, present designation (References in Wood & Bright c1992:218)

Diagnosis: Remotely allied to *amplus* Wood but easily distinguished by the smaller size; by the much longer, conspicuous strial hair and coarser, much more closely set interstitial setae; by the very different male frons; and by other characters described below.

Male: Length 1.6–1.7 mm, 1.9 times as long as wide; color very dark brown. Frons moderately, broadly im-

pressed on lower third to level of antennal insertions, continued on middle third to median line, feebly impressed above to upper level of eyes; median third from epistomal margin almost to level of antennal insertions rather coarsely rugose-reticulate (or minutely granulate), brightly shining and sparsely punctured to slightly above upper level of eyes; vestiture sparse, mostly on margins. Pronotum 0.82 times as long as wide, widest at base; median half armed from near anterior margin to near base by numerous small, confused asperities replacing punctures; surface mostly shining, with areas of weak reticulation mostly on basal third; vestiture of moderately abundant, rather short, fine hair. Elytra 1.27 times as long as wide, 1.8 times as long as pronotum; basal margins each with a single row of crenulations, with no submarginal crenulations; interstriae 1 moderately, others feebly, impressed; interstriae about as wide as striae, smooth, shining, each with a central row of moderately coarse setiferous tubercles. Declivity broadly convex, steep; sculpture about as on disc except striae and interstriae slightly narrower, tubercles smaller (almost obsolete on lower interstriae 1 and 2), 9 not elevated.

Female: Similar to male except frons convex almost to epistoma, sculpture simple; pronotum rather strongly reticulate, crenulations almost entirely replaced by small, shallow punctures.

Distribution: Argentina: Santa Maria, Concepcion, Misiones, M.J. Viana.

Hosts: *Araucaria angustifolis* (Bright & Skidmore 2002:34).

Notes: The above treatment was based on the 2 syntypes that Schedl subsequently labeled as the “holotype” and “allotype” of this species; both are from the same locality. This action was invalid under the International Code on Zoological Nomenclature. Because the females in this genus are often distinguished only with great difficulty, and the males have the truly diagnostic characters, I here designate the male syntype as the lectotype (Schedl’s “allotype”) of *Phthorophloeus argentinensis* Schedl. The female syntype is designated as the lectoallotype (Schedl’s “holotype”).

Phloeotribus truncatus Wood, n. sp.

Plate XVII

Phloeotribus truncatus Wood: Holotype ♂; Quindio, Colombia, on mountain slopes; BMNH, London, designated below

Diagnosis: This is the only known member of this genus in which the elytral declivity is subobliquely truncate; its base is armed by a circumdeclivital ring of conspicuous, blunt spines in both sexes.

Male: Length 2.7–3.3 mm, 1.8 times as long as wide; mature color black. Frons with a shining median callus on slightly more than median half from epistoma to slightly above level of antennal insertions, its surface finely, somewhat irregularly, rather closely punctured; median area above callus concavely impressed on median half almost to upper level of eyes; except for callus, lateral

margins and upper areas finely reticulate, dull, sparse, minute punctures evident; glabrous except epistomal margin; scape with a small tuft of long dark hair near its apex. Pronotum 0.75 times as long as wide; surface dull, very minutely irregular; lateral thirds asperate, median third with a few, small, widely spaced asperities (asperities mostly shining); vestiture mostly abraded, short, sparse. Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; scutellar notch moderately deep; striae moderately, rather gradually impressed, punctures rather deep, most transversely elongate; interstriae convex, almost twice as wide as striae, each ending abruptly behind in an irregular, blunt, circumdeclivital spine, interstitial crenulations mostly narrow, mostly uniseriate, confused near base on 2 and 3. Declivity obliquely truncate, very steep, with a circumdeclivital ring of tubercles from suture above to suture at apex; face irregularly, very broadly convex; striae moderately impressed, punctures distinct, about as large as on disc; interstriae moderately convex, dull, each with about three to five small, irregularly distributed tubercles. Vestiture abraded on most specimens, at least on disc, a few rather short setae sometimes present; on declivity a moderately abundant ground cover of short hair present, longer, somewhat uniseriate hair irregularly present.

Female: Similar to male except frons convex, reticulate, callus not evident, a few isolated granules on upper half; tubercles on discal interstriae and in circumdeclivital ring present, distinctly smaller; declivital interstriae with interstitial tubercles distinctly larger, more numerous (in uniseriate rows).

Distribution: Colombia (Caldas).

Type material: The male holotype, female allotype, and 8 paratypes were taken above Quindio, I-III-1995, Sample A, on mountain slopes, IIE 23265 *Ceroxylon quindiuense*, G. Carillo; 3 paratypes were taken at Caldas, 1994, on *Ceroxylon quindiuense*, P. Baker, IIE 23145; 3 paratypes are from Cajamarca.Tol., V-1992, 2300 m, *Ceroxylon quindiuense*, G. Carillo. The holotype, allotype, and 9 paratypes are in the BMNH, London; 5 paratypes are in the U.S. National Museum, Washington.

Hosts: *Ceroxylon quindiuense* (Palmae).

Phloeotribus amplus Wood

Plate XI

Phloeotribus amplus Wood, 1977:390. Holotype ♂; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:218)

Diagnosis: Pronotal asperities present; declivital interstriae 9 modestly elevated, weakly serrate; size moderately large.

Male: Similar to female except frons broadly, moderately concave from epistoma to upper level of eyes, deepest on upper half; antennal scape with a small tuft of hair; interstitial crenulations and tubercles distinctly larger, rather coarse.

Female: Length 3.2–3.9 mm, 2.0 times as long as wide; color dark brown to black. Frons convex; surface mostly reticulate, punctures small, rather obscure above; middle segment of antennal club 5 times as wide as long. Pronotum 0.84 times as long as wide; lateral areas asperate from near anterior margin to near posterior margin; surface shining; punctures rather coarse, close; vestiture hairlike, moderately abundant, rather short; middle segment of antennal club 6 times as wide as long. Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; bases of interstriae 2–4 armed by a total of about fifteen to twenty submarginal crenulations; striae rather weakly impressed, punctures large, close, deep; interstriae about as wide as striae, surface smooth, shining, crenulations low, sharp, uniseriate, largest about two-thirds as wide as an interstriae, narrower toward declivity. Declivity convex, steep; striae and interstriae narrower than on disc; all interstriae weakly convex, none elevated, tubercles rather sharply pointed, slightly larger than on disc; vestiture hairlike, in uniseriate interstitial rows, seta length equal to slightly more than half distance between rows, within a row equal to length of a seta.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 14-X-1969, 2500 m, No. 59, bole of large felled tree, SLW; Merida, Merida, 29-XII-1969, 1700 m, No. 218, in flight, SLW.

Biology: Taken from biramous, transverse parental tunnels and from larval mines in the phloem tissues of a felled tree 60–80 cm in diameter.

Notes: The above treatment was based on the type series of 13 specimens.

Phloeotribus novateutonicus (Schedl)

Phloeotribus novateutonicus (Schedl), 1951:84 (*Phthorophloeus*). Lectotype ♂; Nova Teuonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:225)

Diagnosis: Distinguished from *vesculus* Wood by the shallowly concave male frons, the upper area convex, smooth, brightly shining, impunctate; by the weakly reticulate pronotum; and by the discal striae being wider than the interstriae.

Male: Length 1.2 mm, 2.1 times as long as wide; color pale brown to brown. Frons broadly, shallowly concave from epistoma to level of antennal insertions, apparently smooth, punctures not clearly evident, area above level of antennal insertions to vertex convex, smooth, brightly shining, impunctate on median four-fifths, lateral and dorsal margins finely, deeply punctured; vestiture on lateral and dorsal margins of rather sparse, short, fine hair. Pronotum 0.86 times as long as wide; surface weakly reticulate; anterior three-fourths of median half with several small crenulations, punctures minute, not clearly evident; vestiture sparse, of rather stout, moderately long setae. Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; basal margins with a strong row of crenulations, submarginal crenulations not evident; striae weakly impressed, punctures coarse, deep; interstriae

slightly narrower than striae, smooth, shining, each with a uniseriate row of rather fine, rounded tubercles. Declivity broadly convex, steep; striae and interstriae narrower than on disc, interstitial tubercles slightly smaller. Vestiture of rows of fine, short strial hair, and uniseriate rows of interstitial erect bristles, length of a bristle about equal to two-thirds distance between rows, spaced within a row by length of a bristle.

Female: Similar to male except frons convex, smooth, shining, uniformly, sparsely punctured throughout; crenulations on pronotum obscure to absent.

Distribution: Brazil: Nova Teutonia, Santa Catarina, VIII-1941, F. Plaumann.

Notes: The above treatment was based on 1 male and 4 female syntypes. The male syntype is here designated as the lectotype of *Phthorophloeus novateutonicus* Schedl. Schedl erroneously designated a female as the "holotype" and a male as the "allotype," an option not available to him from a syntypic series.

Phloeotribus vesculus Wood

Phloeotribus vesculus Wood, 1977:392. Holotype ♀; 5 km W El Pino, Zulia, Venezuela; USNM, Washington (References in Wood & Bright c1992:235)

Diagnosis: Pronotal asperities present; surface reticulate; body stout; color dark brown; male frons with a pair of small tubercles mesad from lateral margin slightly above level of antennal insertion.

Male: Similar to female except frons broadly, moderately concave from epistoma to distinctly below upper level of eyes, a few minute granules on margins at bases of setae, a pair of small tubercles mesad from lateral margins immediately above level of antennal insertions (same position as calluses on female); elytral setae slightly longer and more slender (at least 8 times as long as wide).

Female: Length 1.3–1.4 mm, 2.0 times as long as wide; color dark brown, almost black. Frons with short, transverse impression at epistoma, convex from epistoma to vertex; surface reticulate except for a pair of shining calluses immediately above level of antennal insertion and mesad from lateral margins; vestiture of sparse, stout, short hair; middle segment of antennal club about 5 times as wide as long. Pronotum 0.84 times as long as wide; crenulations on anterolateral areas small, sparse; surface strongly reticulate throughout, setiferous punctures feebly granulate, sparse, very small; vestiture rather sparse, almost scalelike, each about 6 times as long as wide. Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; bases of interstriae 2–3 with a total of about four submarginal crenulations; striae feebly if at all impressed, punctures large, deep; interstriae as wide as striae, surface smooth, with numerous impressed points (micropunctures), tubercles uniseriate, rather small, somewhat pointed (each about half as wide as an interstriae), moderately close. Declivity convex, very steep; striae and interstriae narrower than on disc, tubercles much smaller,

almost obsolete; vestiture restricted to uniseriate rows of interstitial scales arising from posterior margin of tubercles, each scale about six times as long as wide, slightly longer than half distance between rows, spaced within a row by length of a scale.

Distribution: Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 575, *Sterculia pruriens*, SLW; 5 km W El Pino, Zulia, 20-X-1969, 10 m, No. 140, *Ochroma*, SLW.

Hosts: *Ochroma*, *Sterculia pruriens* (det. Balbino Rodriguez).

Biology: Taken from phloem of cut seedlings.

Notes: The above treatment was based on the female holotype and on 1 male.

Phloeotribus profanus Schedl

Phloeotribus profanus Schedl, 1963:212. Holotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:227)

Diagnosis: Distinguished from *nitidicollis* (Eggers) by the smaller size; by the more broadly, more deeply concave male frons; by the smaller strial punctures; and by other characters mentioned below.

Male: Length 1.4 mm, 1.8 times as long as wide; color very dark brown, almost black. Frons broadly, deeply concave from epistoma to very slightly above upper level of eyes; surface apparently reticulate, punctures not evident, upper area with sparse, very fine granules; vestiture of sparse, rather short hair. Pronotum 0.74 times as long as wide; anterior half with small crenulations, surface shining, punctures coarse, shallow, moderately impressed; vestiture of moderate abundance, rather coarse, somewhat short. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; basal margins armed by a strong row of coarse crenulations, true submarginal crenulations not present; striae moderately impressed, punctures rather coarse, distinctly impressed; interstriae very slightly wider than striae, shining, somewhat irregular, convex, each with a uniseriate row of rather coarse, acutely rounded tubercles, these spaced by about diameter of a strial puncture. Declivity broadly convex, steep; striae slightly more deeply impressed than on disc; tubercles about as on disc on interstriae 1–9, of about equal size. Vestiture of uniseriate interstitial rows of erect, short bristles, each arising from posterior base of a tubercle and perhaps ten times as long as wide, about half as long as distance between rows, spaced within a row by slightly more than length of a bristle.

Female: Similar to male except frons broadly convex.

Distribution: Brazil: [Nova Teutonia] Linha Facao, Santa Catarina, VII-1957, F. Plaumann.

Notes: The above treatment was based on the female holotype and the male allotype. The female specimen labeled by Schedl as a paratype of this species (sent on loan by NHMW, Wien) is entirely unrelated and was treated above as *Phloeotribus schedli* Wood.

Phloeotribus nitidicollis (Eggers)

Phloeotribus nitidicollis (Eggers), 1943:347 (*Phthorophloeus*). Holotype ♀; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:225)

Phloeotribus neglectus Schedl, 1964:303. Holotype, sex?; Cochabamba, Bolivia; USNM, Washington, automatic, replacement name for *eggersi* Schedl, 1963:60 (Synonymy and references in Wood & Bright c1992:225). *New synonymy*

Phloeotribus striatus Eggers, 1943:351. Holotype, sex?; Cochabamba, Bolivia; USNM, Washington, preoccupied by Eggers 1943:346

Phloeotribus eggersi Schedl, 1963:60. Holotype, sex?; Cochabamba, Bolivia; USNM, Washington, replacement name for *striatus* Eggers 1943, preoccupied by Schedl (1962:487)

Phloeotribus nebulosus Wood, 1977:390. Holotype ♂; Piedras Blancas 11 km W Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:225). *New synonymy*

Phloeotribus levis Wood, 1977:392. Holotype ♂; Piedras Blancas 10 km E Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:223). *New synonymy*

Diagnosis: Distinguished from *vesculus* Wood by the more slender body form; by the black color; by the shining pronotum; and by the more slender interstitial setae.

Male: Similar to female except frons shallowly, broadly concave from epistoma almost to upper level of eyes, surface rugose-reticulate, lateral margins subacute near level of antennal insertion; antennal scape with a small tuft of hair; interstitial setae slightly stouter, especially on declivity.

Female: Length 1.3–1.8 mm, 2.2 times as long as wide; color black. Frons convex; transversely impressed from epistoma to level of antennal insertion, surface rugose-reticulate, sparse punctures of moderate size above, minute below, obscure; vestiture of sparse, fine, short hair; middle segment of antennal club about 6 times as wide as long. Pronotum 0.90 times as long as wide; anterolateral areas moderately asperate; surface mostly shining, obscure, irregular reticulation in most areas (not uniform); punctures coarse, close, deep, somewhat irregular in size, spaced by 2 diameters of a puncture; vestiture of rather sparse, fine, short hair, longer near lateral margins. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; bases of interstriae 2–4 with a total of about four submarginal crenulations; striae moderately impressed, punctures coarse, deep, close; interstriae as wide as striae, surface smooth, shining, crenulations subacute, moderately close, uniseriate, each about as wide as an interstriae, narrower and tuberculate near declivity. Declivity convex, steep; striae and interstriae narrower than on disc, interstitial tubercles on all interstriae, tubercles rather small and acutely pointed on 1–3, distinctly larger but sparse on 4–8; interstriae 9 strongly, acutely elevated, tubercles rather large, subacute from base to level of interstriae 3, smaller from there to suture; vestiture of interstitial rows of erect, rather fine hair; length of each seta equal to about two-thirds distance between rows, spaced within row by length of a seta.

Distribution: Bolivia to Colombia and Venezuela. Bolivia: Cochabamba [Woytkowski].

Colombia: Piedras Blancas 11 km W Medellin, 15-VII-1970, 2500 m, Nos. 658, 681, 684, *Clusia*, and 17-VII-1970, 2000 m, No. 693, *Croton guianensis*, SLW.

Venezuela: Colonia Tovar, Aragua, 4-V-1970, 1700 m, No. 507, unidentified log, SLW; La Carbonera Experimental Forest 50 km NW Merida, Merida, 14-X-1969, 2500 m, No. 51, *Clusia*, SLW; Merida, Merida, 22-IX-1969, 1700 m, No. 9, *Clusia*, SLW.

Hosts: *Clusia*, *Croton guianensis*.

Biology: Taken from the phloem of felled small trees.

Notes: The above treatment was based on the holotypes of *Phthorophloeus nitidicollis* Eggers, *Phthorophloeus neglectus* Schedl, *Phloeotribus striatus* Eggers (1943:351), on the type series of 124 specimens of *Phloeotribus nebulosus* Wood, and on the type series of 3 specimens of *Phloeotribus levis* Wood. There is considerable variation in this species that may cause problems in identification.

Phloeotribus erinaceus Schedl

Phloeotribus erinaceus Schedl, 1967:7. Holotype ♂; Itu, Fazenda Pau d'Alho, Santa Catarina, Brazil; MZUSP Sao Paulo (References in Wood & Bright c1992:221)

Diagnosis: Distinguished from *nitidicollis* (Eggers) by the much more coarsely punctured pronotum disc and striae; by the strongly elevated declivital interstriae 9; and by the much larger tubercles on declivital interstriae 3, 5, and 7; and by many other characters described below. These 2 species are not closely related.

Male: Length 1.8 mm, 1.9 times as long as wide; color dark reddish brown. Frons moderately, rather narrowly concave from epistoma to upper level of eyes, lateral margins moderately subacute on middle third, without a denticle; concave area mostly smooth, shining, punctures mostly obscure, sparse, small; vertex rugose-reticulate; setae sparse, hairlike, rather short except longer and more numerous on epistoma. Pronotum 0.76 times as long as wide; widest at base; sides moderately, arcuately converging to rather broadly rounded anterior margin; summit indefinite, on basal third of pronotum length; anterior slope on median three-fourths of anterior half, armed by many narrow, rather coarse asperities; disc smooth, shining, punctures rather coarse, deep, mostly spaced by distance less than diameter of a puncture; setae on asperate area rather stout (about 10 times longer than wide), of moderate abundance, longer and more slender on disc. Elytra 1.35 times as long as wide, 1.8 times as long as pronotum; disc occupying basal 60 percent of elytra length; basal margin mostly straight, scutellar notch rather narrow, moderately deep, each with about 10 crenulations; striae slightly impressed near declivity, not impressed on basal half, slightly wider than interstriae, punctures large, deep, close; interstriae smooth, shining, crenulations uniseriate on basal half, moderately coarse toward declivity, almost all punctures replaced by crenulations. Declivity very broadly convex, very steep; striae similar to those on disc, punctures

distinctly smaller; interstriae 1 and 2 narrower than on disc, crenulations small to obsolete, 3 feebly elevated and armed by one rather large and about four moderate, pointed tubercles; apex of 5 and 7 each with one or two equally large tubercles; ventrolateral margin strongly, acutely elevated and serrate from striae 1 to interstriae 9 near declivity (six or seven serrations). Vestiture consisting of uniseriate interstitial rows of almost hairlike setae, each on disc slightly shorter than distance between rows, slightly longer and equal to this distance on declivity.

Distribution: Brazil: Faz. Pau d'Alho itu, Sao Paulo, II-1959, U. Martins.

Notes: The above treatment was based on the male holotype.

Phloeotribus harringtoni Blackman

Phloeotribus harringtoni Blackman, 1943:388. Holotype ♀; Aguaray, Argentina; USNM, Washington (References in Wood & Bright c1992:222)

Diagnosis: Distinguished from *fici* Wood by the larger size; by the absence of small tubercles on declivital interstriae 1; and by the less numerous, slightly longer interstitial setae.

Male: Length 2.1 mm (female 2.2 mm, 2.2 times as long as wide); color very dark brown. Frons resembling *hirtus* Wood except concave area deeper, more extensive, extending to upper level of eyes; brush on antennal scape small, consisting of about 8 setae. Pronotum 0.80 times as long as wide; surface smooth, shining between punctures, punctures rather coarse, close, of variable size; vestiture of slender, long bristles, unusually long on disc. Left elytron missing from holotype; base of interstriae 2 with two submarginal crenulations, 3 with one; striae weakly impressed, punctures very large, deep, punctures transversely wider than long; interstriae slightly narrower than striae, each (2–9) with a uniseriate row of fine tubercles, except tubercles absent on 1. Declivity convex, steep; striae 1 and 2 more strongly, more narrowly impressed, punctures deep, half as large as on disc; interstriae 1 slightly wider and more broadly convex than 2 or 3 (rather narrowly convex); 1 with more numerous, confused punctures (no tubercles), 2 with one small, pointed spine at base, uniseriately punctured, 3 with three rather coarse, pointed spines widely spaced on upper half, 5, 7, and 9 each with two rather coarse spines near their apices, 9 moderately elevated near its apex. Vestiture of erect, coarse setae in uniseriate rows, those on anterior disc and lower declivity each about equal in length to distance between rows, those near base of declivity slightly longer.

Female: Similar to male except frons convex, reticulate, rather closely punctured, with sparse, rather coarse, moderately long, coarse hair; bases of interstriae 2–5 each with two or three submarginal crenulations; all tubercles on elytral declivity smaller; setae on pronotum and elytra about two-thirds as long.

Distribution: Argentina: Aguaray & Tartegal [Salta Prov.], 19-21-X-1920, G.L. Harrington.

Notes: The above treatment was based on the female holotype and on the male allotype (left elytron missing).

Phloeotribus jujuya Blackman

Phloeotribus jujuya Blackman, 1943:389. Holotype ♀; Santa Clara, Jujuy, Argentina; USNM, Washington

Diagnosis: This species is not in the above key. It was based on the female holotype and appears to key out to *harringtoni* Blackman, but it is larger, the frons is not reticulate, and other details indicate it is of a different species.

Female: Length 2.4 mm, 2.14 times as long as wide; color medium reddish brown. Frons convex, mostly smooth, shining, punctures small to minute, close; middle half of median line from epistoma to upper level of eyes with a weak, double carina, line between summits very narrow, rather deep; setae fine, hairlike, rather short, moderately abundant; vertex rugose-reticulate; antennal club segments 1 and 2 each about twice as wide as long. Pronotum 0.80 times as long as wide; widest at base, sides moderately arcuate and converging toward rather broadly rounded, unarmed anterior margin; summit indefinite, at middle of pronotum length; lateral fourths with moderate crenulations from near base to anterior margin, median half anterior to summit feebly to weakly crenulate and intermixed with a few obscure punctures, basal half with an impunctate median line then rather close, coarse, deep punctures; vestiture hairlike, rather numerous, of moderate length. Elytra 1.7 times as long as wide, 2.1 times as long as pronotum; disc occupying basal 67 percent of elytra length; basal margins each armed by 9 crenulations; scutellar notch subacute, rather deep; striae moderately impressed, punctures coarse, deep, close; interstriae as wide as striae, smooth, shining, punctures not evident, transverse crenulations on basal third of disc rather coarse, confused on 2, uniseriate elsewhere, transcending to uniseriate conical tubercles on declivity; interstriae 1–3 equal in height, 4–8 end before attaining apical margin. Vestiture on interstriae in rows, short on disc and sides, minute to obsolete on declivity.

Distribution: Argentina: Santa Clara, Jujuy, 23-IX-1921, G.L. Harrington.

Notes: The above treatment is based on the female holotype.

Phloeotribus hirtus Wood

Phloeotribus hirtus Wood, 1977:393. Holotype ♂; Caparrapi, Cunadin, Colombia; USNM, Washington (References in Wood & Bright c1992:222)

Diagnosis: Color black; declivital interstriae 9 very strongly elevated and coarsely serrate; interstitial tubercles on declivity of irregular size and spacing; interstitial setae very long.

Male: Similar to female except frons broadly, rather deeply concave from epistoma to upper level of eyes; scape with a small tuft of long hair; major denticles on odd-numbered declivital interstriae distinctly larger.

Female: Length 1.9–2.0 mm, 1.9 times as long as wide; color very dark brown. Frons transversely impressed from epistoma to level of antennal insertion, convex above; surface mostly reticulate, punctures rather coarse, close, somewhat obscure; vestiture of inconspicuous, fine, short, sparse hair; middle segment of antennal club 6 or more times as wide as long. Pronotum 0.81 times as long as wide; asperities present on anterolateral areas; surface shining, punctures coarse, close, deep, interspaces equal to less than width of a puncture; vestiture of sparse very long hair. Elytra 1.3 times as long as wide, 1.9 times as long as pronotum; bases of interstriae 2–5 armed by a total of about five submarginal crenulations; striae weakly impressed at base, more strongly by base of declivity, punctures very coarse, close, deep; interstriae narrower than striae, smooth, shining, with a few impressed points, tubercles uniseriate, rather narrow, subacutely pointed, more widely spaced within a row than normal. Declivity convex, steep; striae and interstriae narrower than on disc; striae punctures confluent; interstriae rather narrowly convex, tubercles on 1–8 rather small except 1, 3, 5, and 7 usually each with one tubercle larger than others, 2 and 4 sometimes unarmed; interstriae 9 strongly, narrowly, acutely elevated to suture, its crest coarsely serrate; vestiture of interstitial rows of fine, long, erect hair, longest setae equal in length to combined width of two striae plus two interstriae.

Distribution: Colombia: Caparrapi, Cunadin, 28-V-1959, arbol de sangregao, A. Diaz.

Notes: The above treatment was based on the type series of 10 specimens.

Phloeotribus fici Wood

Phloeotribus fici Wood, 1977:393. Holotype ♂; Universidad de los Andes Campus, Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:221)

Diagnosis: Distinguished from *hirtus* Wood by the absence of tubercles on declivital interstriae 2 and 4; and by the slightly shorter interstitial setae.

Male: Length 1.6–1.7 mm, 2.1 times as long as wide; color black. Frons almost flat from epistoma to upper level of eyes (not distinctly concave); surface strongly reticulate, punctures obscure, a few small, scattered granules on upper half; middle segment of antennal club about 5 times as wide as long. Pronotum 0.82 times as long as wide; asperities on anterior third present, very small; punctures coarse, deep, close, of irregular size and shape; vestiture of sparse, moderately long, coarse hair. Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; bases of interstriae 2–4 with a total of four submarginal crenulations; striae weakly impressed at base, rather strongly toward base of declivity, punctures coarse, deep, close; interstriae slightly wider than striae,

surface smooth, shining, crenulations on 3 uniseriate, each almost as wide as an interstriae, reduced (but present) on 2 and 4. Declivity convex, steep; striae and interstriae narrower than on disc; interstriae 2, 4, and lower 6 and 8 unarmed, 1 slightly elevated and armed by small tubercles, 3, 5, and 7 slightly elevated and each armed by about three coarse, pointed tubercles, 9 strongly, narrowly elevated to suture and armed by a row of coarse, pointed denticles; vestiture of interstitial rows of coarse setae, each about as long on disc as distance between rows, longer on declivity.

Distribution: Venezuela: Universidad de los Andes Campus, Merida, Merida, 7-X-1969, 1700 m, Nos. 5, 42, *Ficus* (strangler fig), SLW.

Biology: Taken from phloem of the bole of a large, felled tree.

Notes: The above treatment was based on the type series of 2 males.

Phloeotribus rudis Eichhoff, n. status

Phloeotribus rudis Eichhoff, 1868:149. Syntypes (?) ♂; Brazil; 1 in Hamburg Museum, lost, 2 in IRSNB, Brussels (Synonymy and references in Wood & Bright c1992:232)

Phloeotribus puncticollis Chapuis, 1869:45. Holotype ♀; Sao Paulo, Brazil; IRSNB, Brussels

Phloeotribus contractus Chapuis, 1869:46. Lectotype ♂; Colombia; IRSNB, Brussels, present designation by Wood (References in Wood & Bright c1992:220). *New synonymy*

Phloeotribus peruensis Schedl, 1942:67. Holotype ♂; Rio Toro, Peru; NHMW, Wien (References in Wood & Bright c1992:226). *New synonymy*

Phthorophloeus striatus Eggers, 1943:346. Holotype ♂?; Cochabamba, Bolivia; NHMW, Wien (References in Wood & Bright c1992:234). *New synonymy*

Phloeotribus lineatus Eggers, 1951:148. Holotype ♀; Blumenau, Brazil; NHMW, Wien (References in Wood & Bright c1992:224). *New synonymy*

Diagnosis: Mesal portion of posterior margin of prothorax conspicuously extended caudad into scutellar notch; surfaces of pronotum and elytra smooth, shining; size smaller than in allied species.

Male: Similar to female except antennal bases displaced slightly mesad, lower frons very slightly impressed; scape bearing a small tuft of long hair.

Female: Length 2.1–2.9 mm, 1.7 times as long as wide; color very dark brown. Frons flattened from epistoma to level of antennal insertion, convex above; surface reticulate, punctures rather coarse, moderately deep, larger above, fine below level of antennal insertion; vestiture sparse, short; middle segment of antennal club about 10 times as wide as long. Pronotum 0.86 times as long as wide; basal margin strongly, subacutely extending caudad into scutellar notch; asperities present in anterolateral areas; surface shining, punctures moderately coarse, deep, close, of irregular size, interspaces with impressed points, each averaging less than half as wide as diameter of a puncture; setae sparse, stout, rather short; middle segment of antennal club about 10 times as wide as long. Elytra 1.1 times as long as wide, 1.3

times as long as pronotum; bases of interstriae 2–4 with a total of more than 12 submarginal crenulations; striae narrowly, deeply impressed, punctures small, somewhat confluent; interstriae twice as wide as striae, shining, with fine punctures, crenulations close, uniseriate, at base each about two-thirds as wide as an interstriae, half as wide at base of declivity. Declivity convex, steep; striae and interstriae narrower than on disc; interstriae 1–4 convex, each armed by a row of small tubercles, 5–8 with slightly larger tubercles, 9 modestly elevated to suture, rather finely serrate; vestiture of short, stout setae, on 2–8 each about one-fourth as long as distance between rows, distinctly longer on 1 and 9.

Distribution: Colombia and Venezuela to Bolivia and Brazil.

Bolivia: Cochabamba [F. Woytkowski].

Brazil: Bahia, Cepec, Ilheus, I-III-1981, blacklight, Kaston; Blumenau; Santa Catarina, Deyr.; Sao Paulo, Dejean.

Colombia: Colombia, Dejean; 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 601, *Pseudoolmedia*, SLW.

Peru: Leonpampa, Dep. Huanuco, 11-30-III-1937, 800 m, jungle, No. 3811, F. Woytkowski; Rio Toro.

Venezuela: 9 km S Barancas, Barinas, 1-X-1969, *Inga*, SLW; 8 km SW Bumbum, Barinas, 11-II-1970, 150 m, No. 326, tree limb, SLW; 40 km E Canton, Barinas, 8-III-1970, No. 353, *Brosimum*, SLW; 10 km SE Miri, Barinas, 8-II-1970, 150 m, No. 297, *Brosimum*, SLW.

Biology: Taken from transverse, biramous parental tunnels in the phloem of branches 4–10 cm in diameter.

Notes: The above treatment was based on 224 specimens. This name is based on 2 specimens in the Chapuis Collection at the Brussels Museum that were examined and labeled by Eichhoff as *rudis*. They are presumed to be syntypes. The Eichhoff syntypes that were in the Hamburg Museum were destroyed during World War II. I also compared specimens directly to the holotypes or syntypes of *puncticollis* Chapuis (holotype examined), *peruensis* Schedl, *lineatus* Eggers, *striatus* Eggers (holotypes examined), and *contractus* Chapuis (lectotype examined), all are of the same species. The first syntype of *P. contractus* Chapuis, a male, is here designated as the lectotype of that species. The Chapuis specimen of the nomen nudum *villosulus* Lacordaire, from Cayenne, was also examined and is also of this species. The name *rudis* Eichhoff is restored to full species status; it is not a synonym of *setulosus* Eichhoff.

Phloeotribus erosus Schedl

Phloeotribus erosus Schedl, 1951:83. Lectotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:221)

Diagnosis: Distinguished from *sulcifrons* Chapuis by the absence of a strong, median sulcus of the upper female frons; by the narrower discal interstriae; and by the small, discal punctures lacking interstitial setae.

Male: Length 2.5–2.8 mm, 1.7 times as long as wide; color dark reddish brown. Frons broadly, rather strongly concave from epistoma to well above upper level of eyes, deepest near center, surface almost smooth, obscurely reticulate on upper third, minute, obscure punctures on lower half larger, very shallow punctures above eyes; vestiture restricted to lower two-thirds of fine, short, rather sparse hair; lateral margins subacute below level of antennal insertion (simple). Pronotum 0.83 times as long as wide; crenulations on less than anterior half small, not close, extending laterally to basal fourth, and submargin (laterally) armed by 10–12 serrations; surface shining, smooth between punctures, punctures close, moderately coarse, deep; vestiture of rather short, moderately fine hair, apparently sparse. Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; striae moderately, rather abruptly impressed, punctures small, rather distinct; interstriae twice as wide as striae at base, as wide as striae at base of declivity, crenulations close, acute, moderately high, most one-third as wide as an interstriae, a few half as wide, confused, punctures between crenulations small, close, confused, without a seta (except at suture). Declivity occupying posterior half, broadly convex, steep; striae narrower than on disc; interstriae distinctly wider than striae, crenulations reduced to a uniseriate row of moderately small tubercles on each. Vestiture consisting of erect setae arising from crenulations and tubercles, each of moderate length and about equal in length to half distance between declivital rows.

Female: Similar to male except frons convex, surface mostly reticulate; elytral setae slightly shorter.

Distribution: Argentina to Brazil.

Argentina: Cited in Wood & Bright c1992:221.

Brazil: Nova Teutonia [Santa Catarina], IV-1944, F. Plaumann.

Notes: The above treatment was based on the male lectotype, and on 1 other male and 2 females in the NHMW, Wien. Schedl (1979:91) had, subsequent to publication of the original description, incorrectly labeled a male syntype as the allotype of this species, and 1 of the females as the (invalid) holotype. The first male syntype in the Schedl series is here designated as the lectotype of *Phloeotribus erosus* Schedl.

Phloeotribus sulcifrons Chapuis

Phloeotribus sulcifrons Chapuis, 1869:45. Holotype ♀; Nouvelle Grenada [presumably Colombia]; IRSNB, Brussels (References in Wood & Bright c1992:234)

Diagnosis: Distinguished from *pilula* (Erichson) by the absence of reticulation on both pronotum and elytra; and by the strong, rather broad median sulcus on the female frons.

Female: Length 3.2 mm, 1.6 times as long as wide; color almost black. Frons with a moderately strong median sulcus from vertex to slightly above level of antennal insertion, a feeble continuation of this impression to

each antennal insertion; surface coarsely punctate-granulate to upper level of eyes in lateral areas, more nearly smooth and with sparse punctures in sulcus; area below level of antennal insertion more finely punctured, without any granules; vertex at least partly rugose-reticulate; vestiture of fine, short, inconspicuous hair. Antennal club with segments each about 8 times wider than long. Pronotum 0.90 times as long as wide; asperities confined to lateral fourths and near anterior margin; rather coarsely, deeply, very closely punctured, spaces between punctures smooth, shining, about equal in width to one-fourth diameter of a puncture; vestiture very sparse, hairlike. Elytra about 1.1 times as long as wide (1 elytron displaced, measurement uncertain), 1.3 times as long as pronotum; striae moderately, abruptly impressed, punctures small, rather deep; interstriae almost three times as wide as striae, surface between crenulations smooth, shining, crenulations close, acute, rather high, transversely narrow (most equal to less than one-third width of an interstriae), minute punctures apparently numerous, confused, most obscure; a minute, hairlike seta arising from posterior base of each crenulation, confused (no erect bristles). Declivity broadly convex, steep; striae wider, interstriae narrower than on disc; interstitial crenulations reduced at base to one central row of tubercles on each interstriae, these almost obsolete by apex; vestiture apparently similar to that of disc.

Distribution: Colombia: "Nouvelle Grenada, Dejean."

Notes: The above treatment was based on the female holotype.

Phloeotribus cylindricus Schedl

Phloeotribus cylindricus Schedl, 1951:82. Lectotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:220)

Diagnosis: Distinguished from *opacicollis* Eggers by the smooth, shining elytral interstriae (reticulation obscure to absent); by the much broader crenulations on the discal interstriae, a much smaller puncture on their posterior slope; and by the slightly smaller size.

Male: Length 2.3–2.6 mm, 1.8 times as long as wide; color very dark brown. Frons broadly, moderately impressed (shallowly concave) from epistoma to upper level of eyes; lateral margins on lower half subacutely elevated, stronger at level of antennal insertions (no denticle); surface reticulate, sparse small granules on upper half, a few small, obscure punctures below; vestiture of rather long, moderately abundant, coarse hair. Pronotum 0.90 times as long as wide; basal margin sinuately extending into scutellar notch; surface reticulate, irregularly, closely, rather deeply punctured, interiors of punctures smooth, shining; anterior margin armed by about 8 coarse serrations, about 2 moderately coarse submarginal asperities on each side; vestiture coarse, rather short. Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; scutellar notch moderately deep; about 10 submarginal crenulations; striae rather deeply, abruptly impressed,

punctures rather small, deep, partly confluent; interstriae slightly wider than striae, surface mostly shining, weakly reticulate in some areas, discal crenulations rather broad (about half to two-thirds as wide as an interstriae, their posterior slope with a comparatively small setiferous puncture. Declivity convex, steep; sculpture much as on disc except striae and interstriae narrower, subequal in width, interstitial crenulations reduced to a rather small tubercle. Vestiture of uniseriate rows of suberect interstitial bristles, each bristle equal in length to about half distance between rows.

Female: Similar to male except frons convex, lateral margins not elevated; interstitial setae very slightly longer.

Distribution: Brazil: Nova Teutonia, Santa Catarina, XI-1940, F. Plaumann.

Notes: The above treatment was based on 1 male syntype and 1 female syntype. Schedl (1979:74) subsequently labeled this female syntype as the "holotype" of this species, an act not permitted under the International Code on Zoological Nomenclature. Because diagnostic characters are more precise in the male, I here designate this male syntype as the lectotype of *Phloeotribus cylindricus* Schedl, as indicated above.

Phloeotribus opacicollis Eggers

Phloeotribus opacicollis Eggers, 1943:353. Holotype ♂; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:225)

Diagnosis: Distinguished from allied species (see key above) by the smaller, more slender body; by the dull prothorax with deep, circular punctures with their interiors and margins brightly shining; and by the uniseriate setae on discal interstriae 2 and 3.

Male: Length 2.2 mm, 1.9 times as long as wide; color dull black. Frons narrow, shallowly concave from epistoma almost to upper level of eyes, surface rugose-reticulate on upper one-third, almost smooth, shining near epistoma; lateral margins below level of antennal insertions subacutely, rather weakly elevated; vestiture of sparse, stout, evenly distributed setae. Pronotum 0.82 times as long as wide; asperities confined to less than anterior half, narrow, moderately high, 8 arm anterior margin; surface dull, almost rugose-reticulate, punctures on posterior half almost circular, most rather coarse, their interiors brightly shining; setae sparse, coarse, mostly on margins. Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; striae deeply, abruptly impressed, punctures almost confluent but distinct, shining; interstriae almost twice as wide as striae, strongly rugose-reticulate, each with a row of rather broad, moderately high crenulations, a setiferous puncture on their posterior slope. Declivity broadly convex, steep; interstriae as narrow as striae, each with a uniseriate row of small, pointed tubercles to apex. Vestiture of uniseriate interstitial rows of stout bristles, each bristle about half as long as distance between rows.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the male holotype.

Phloeotribus incanus Wood, n. sp.

Plate XIII

Phloeotribus incanus Wood: Holotype ♂; Chanchamyo in Junin, Peru; DEI, Muncheberg, designated below

Diagnosis: Allied to *suturalis* Eggers except distinguished by the discal interstriae being confused only on the basal one-half and uniseriate from there to apex of declivity; and by numerous other differences described below.

Male: Length 2.9–3.0 mm, 1.5 times as long as wide; color black. Frons shallowly, broadly, somewhat subconvexly impressed from epistoma to slightly below upper level of eyes; epistomal margin shining, not higher in median area; surface reticulate, rather finely punctured on lower half, more coarsely above, with no granules; lateral margins at level of antennal insertions rather modestly elevated, vestiture of short, sparse, fine hair; antennal scape with a small brush of dark hair; segments of antennal club each about 6 times as wide as long. Pronotum 0.90 times as long as wide; surface finely rugose-reticulate; asperities small except at anterolateral margins, punctures coarse and deep on basal third; vestiture abraded, apparently of short, stout, sparse hair. Elytra 1.0 times as long as wide, 1.3 times as long as pronotum; striae rather abruptly, somewhat deeply impressed, punctures moderately large, distinctly impressed; interstriae slightly more than twice as wide as striae, surface rugose-reticulate, crenulations on about basal one-third to one-half, broad, confused, rather poorly formed, varying in width from one-third to two-thirds width of an interstriae, narrowed and uniseriate on posterior disc and declivity; tubercles mostly obsolete on lower half of declivity, striae and interstriae narrower than on disc. Declivity broadly convex, steep. Vestiture of short, slender hair, each seta equal in length to about one-third width of an interstriae, confused on basal half of disc, uniseriate behind and on declivity.

Female: Similar to male except frons more nearly flattened, lateral margins more weakly elevated; scape without a tuft of hair; pronotal asperities larger; interstitial crenulations on disc narrower, higher, confused on slightly more than basal half.

Distribution: Peru (Junin).

Type material: The male holotype, female allotype were taken at Chanchamyo in Junin, Strohmeier Collection; 2 male paratypes are from Cumbase, Strohmeier Collection. The holotype, allotype, and 1 paratype are in DEI, Muncheberg; 1 paratype is in the USNM, Washington.

Phloeotribus rugulosus Eggers

Phloeotribus rugulosus Eggers, 1951:147. Lectotype ♂; Corumba, Mato Grosso, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:230)

Diagnosis: Distinguished from *suturalis* Eggers by the smooth, shining surface between punctures on disc of pronotum; by the more abruptly, more deeply impressed discal striae; and by other characters described below.

Male: Length 2.4–2.9 mm, 1.6 times as long as wide; color dark brown. Frons moderately, broadly, subconvexly impressed from epistoma to upper level of eyes; epistoma smooth, shining, weakly elevated on median third; lower half of impressed area smooth, shining, closely punctured, upper half reticulate, more deeply impressed at central fovea, somewhat rugose on upper third; sparse, short vestiture hairlike; scape ornamented by a tuft of long hair; segments of antennal club each at least 6 times as wide as long. Pronotum 0.90 times as long as wide; asperities fine, mostly on anterior half; surface smooth between punctures on posterior half, punctures of somewhat irregular small size; vestiture of short, rather stout, inconspicuous hair. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; striae narrowly, abruptly, rather deeply impressed, punctures small, obscure to obsolete; interstriae about three times as wide as striae, surface mostly rugose-reticulate, crenulations mostly less than one-third as wide as an interstriae, moderately high, subacute, confused from base to margin of declivity (except uniseriate on 1). Declivity broadly convex, steep; interstriae narrower than on disc, about one and one-half times as wide as striae, crenulations reduced to a uniseriate row of tubercles on each interstriae, those on 1 and 2 smaller than in lateral areas. Vestiture of short, stout, pointed hair, each seta equal in length to half width of a discal interstriae, not longer on declivity.

Female: Similar to male except frons convex, a transverse impression just above epistoma, another at level of fovea, lateral margins weakly elevated below; asperities on pronotum larger.

Distribution: Brazil: Jatahy in Goyaz, Strohmeier Collection; Rondon in Parana, VIII-1952, 25-X-1952, VII-1962, F. Plaumann.

Notes: The above treatment was based on the male lectotype from Corumba, present designation, on Schedl's female syntype, and on 21 other specimens, 2 of which were identified by Eggers and compared by him to the syntypes. Bright & Skidmore (1997:50) report this species from Paraguay. This record should be confirmed before it is accepted.

Phloeotribus vestitus Eggers

Phloeotribus vestitus Eggers 1943:349. Holotype ♀; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:235)

Diagnosis: Distinguished by the confused setae on discal interstriae 1–9; by the confused declivital interstitial tubercles on 1–4; and by the longer erect interstitial setae.

Female: Length 2.6 mm, 1.6 times as long as wide; color dark reddish brown. Frons convex as in females of related species; surface reticulate, granulate-punctate; vestiture short, rather abundant; segments of antennal club each about 4–6 times as wide as long. Pronotum 0.81 times as long as wide; surface rather weakly reticulate, small, rather numerous asperities on lateral thirds, somewhat granular on anterior third, disc very closely, rather deeply punctured, punctures varying in size, small to moderately coarse, spaces between punctures equal to less than one-fourth diameter of a puncture; vestiture of sparse, rather short, stout setae. Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; striae abruptly, rather weakly impressed, punctures rather small, subconfluent, distinctly impressed; interstriae about three times as wide as striae, surface densely micro-punctate (almost microgranular), and with confused, close tubercles, each tubercle narrow (about one-fifth as wide as an interstriae), pointed, moderately high, extending from base to base of declivity. Declivity broadly convex, steep; striae slightly more strongly impressed than on disc; interstriae 1–9 rather flat, at least twice as wide as striae, 1–4 with tubercles confused on at least basal half. Vestiture of slender erect, pointed setae, confused on disc, mostly uniseriate on lower declivity, each about equal in length to two-thirds width of an interstriae.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the female holotype.

Phloeotribus suturalis Eggers

Phloeotribus suturalis Eggers, 1943:349. Holotype ♀; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:234–235)

Diagnosis: Distinguished from *vestitus* Eggers by the more distinctly convex declivital interstriae 1–4, with tubercles in uniseriate rows; and by the shorter elytral setae.

Female: Length 2.7 mm, 1.7 times as long as wide; color dark reddish brown. Frons similar to *vestitus* except less strongly convex, transverse impression stronger from epistomal margin to level of antennal insertions; segments of antennal club each less than 4 times as wide as long. Pronotum 0.80 times as long as wide; as in *vestitus* except asperities smaller. Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; striae as in *vestitus* except much more numerous, closer, more strongly confused on 1–9. Declivity resembling *vestitus* except interstriae 1–4 more distinctly convex, tubercles mostly uniseriate on lower two-thirds, slight confusion on 2 and 3. Vestiture of erect setae only, short, stouter than in *vestitus*, longest setae each equal in length to one-fourth to one-third width of an interstriae.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the female holotype.

Phloeotribus uniseriatus Eggers

Phloeotribus uniseriatus Eggers, 1943:350. Lectotype ♀; Cochabamba, Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:35 (References in Wood & Bright c1992:235)

Diagnosis: Distinguished from *rudis* Eichhoff by the larger size; by the reticulate surfaces of pronotum and elytra; and by characters of the frons.

Male: Similar to female except antennal insertions distinctly displaced mesad, surface below level of antennal insertions impressed, smooth, shining, finely, densely punctured; interstitial tubercles almost obsolete, bristles stouter and slightly longer.

Female: Length 2.5–3.0 mm, 1.7 times as long as wide; color very dark brown. Frons convex; surface strongly rugose-reticulate above level of antennal insertion, reticulate below, punctures rather coarse, shallow, close, obscured by rugosity; vestiture of sparse, short, stout, inconspicuous hair; middle segment of antennal club about 10 times as wide as long. Pronotum 0.82 times as long as wide; asperities present in lateral areas; more broadly convex than in *rudis*, surface strongly reticulate, dull, punctures smaller; vestiture about as in *rudis*. Elytra 1.04 times as long as wide, 1.4 times as long as pronotum; bases of interstriae with a total of about fifteen poorly formed submarginal crenulations; striae abruptly, narrowly, strongly impressed, punctures mostly confluent, obscure; interstriae three times as wide as striae at base, narrower at base of declivity, surface rugose-reticulate, dull, crenulations weak, almost obsolete, tubercles clearly indicated near base of declivity. Declivity convex, steep; striae and interstriae narrower than on disc, each interstriae with a row of low, poorly formed tubercles; vestiture of interstitial rows of short bristles, each seta stout, length of those on 2–8 about equal to one-third distance between rows, slightly longer on 1 and 9.

Distribution: Peru and Bolivia to Mato Grosso in Brazil.

Bolivia: Cochabamba.

Brazil: 21°31'S, 51°46'W, Mato Grosso, 5-XI-68, R.A. Beaver.

Peru: Leonpampa, Dep. Huanuco, 15-30-XII-1937, 800 m, jungle, No. 3811, F. Woytkowski; San Beni, Dep. Junin, 18-IX-1935, 840 m, F. Woytkowski.

Notes: The above treatment was based on 3 males and 1 female. One male was compared by me directly to the lectotype of *Phloeotribus uniseriatus* Eggers.

Phloeotribus pilula (Erichson)

Plate XIV

Phloeotribus pilula (Erichson), 1847:138 (*Hylesinus*). Lectotype ♂; Peru; MNB, Berlin, designated by Wood (1973:181); Synonymy and references in Wood & Bright c1992:227)

Phloeotribus obliquus Chapuis, 1869:45. Syntypes, sex?; Mexique, Nouvelle Grenada; IRSNB, Brussels

Phloeotribus obesus Kirsch, 1873:283. Holotype, sex?; Peru; SMTI, Dresden

Phloeotribus manni Blackman, 1943:385. Holotype ♀; Rio Madeira, Brazil; USNM, Washington

Phloeotribus australis Schedl, 1953:80. Holotype ♂; intercepted at Queensland, Australia; NHMW, Wien

Diagnosis: Distinguished from *uniseriatus* Eggers by the more strongly, more extensively impressed male frons; by the different surface sculpture of the frons and pronotum; and by the more conspicuous interstitial crenulations.

Male: Similar to female except frons shallowly concave from epistoma to upper level of eyes, antennal insertions displaced slightly mesad; interstitial crenulations distinctly higher.

Female: Length 2.4–3.4 mm, 1.6 times as long as wide; color very dark brown, almost black. Frons somewhat flattened below level of antennal insertion, convex above; surface reticulate and rather coarsely punctured above, shining and finely punctured below; vestiture of fine, short, rather sparse hair; middle segment of antennal club about 10 times as wide as long. Pronotum 0.83 times as long as wide; about as in *rudis* Eichhoff except surface slightly reticulate (more strongly convex than in *uniseriatus*), punctures coarse, rather deep. Elytra 1.0 times as long as wide, 1.3 times as long as pronotum; submarginal crenulations at bases of interstriae 2–4 poorly formed, rather abundant; striae abruptly, narrowly, deeply impressed, punctures confluent, interstriae almost three times as wide as striae, surface minutely rugose-reticulate, crenulations low, poorly formed, more distinct than in *uniseriatus*. Declivity about as in *uniseriatus*; vestiture fine, very short, setae about one-fifth as long as distance between rows.

Distribution: Mexico (Chiapas) to Brazil.

Bolivia: Bright & Skidmore (1997:49).

Brazil: Rondon (24°38'S, 54°7'W), F. Plaumann; Mato Grosso (12°31'S, 51°46'W), XII-1968, RA. Beaver.

Peru: Tingo Maria, Monson Valley, 18-IX-1954, E.I. Schlinger & E.S. Ross; Pozuzo [Huanuco Prov.].

Venezuela: 9 km S Barancas, Barinas, 1-X-1969, 150 m, No. 30, *Brosimum*, SLW; 40 km E Canton, Barinas, 8-III-1970, 70 m, No. 390, *Brosimum*, SLW; 10 km S Miri, Barinas, 8-II-1970, 150 m, No. 297, *Brosimum*, SLW.

Biology: Taken from phloem in large limbs in transverse, biramous parental tunnels.

Notes: The above treatment was based on 90 specimens, 3 males of which I compared directly to the lectotype of *Hylesinus pilula* Erichson. The syntypes of *obliquus* Chapuis, and the holotypes of *obesus* Kirsch, *manni* Blackman, and *australis* Schedl were examined.

Phloeotribus tetricus Wood

Phloeotribus tetricus Wood, 1977:389. Holotype ♂; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:235)

Diagnosis: Setae on interstriae short, stout, those on 2 and 3 numerous, confused; striae punctures very large, interstriae half as wide as striae; alternate interstriae armed by sharply pointed tubercles.

Male: Similar to female except epistoma with a subacutely elevated transverse carina on at least median half; rather shallowly, broadly impressed from carina to slightly above level of antennal insertions; scape with a small tuft of hair.

Female: Length 1.8–2.1 mm, 1.9 times as long as wide; color reddish brown. Frons reticulate; flattened from epistoma to level of antennal insertions, convex above; punctures coarse, close, shallow on upper half, fine below; subglabrous, a few fine, hairlike setae below, middle segment of antennal club about 3–4 times as wide as long. Pronotum 0.83 times as long as wide; anterolateral areas rugose, asperities very poorly developed, often obscure; surface smooth, shining, punctures coarse, close, rather deep, irregular in size, interspaces between punctures equal in width to less than one-half diameter of a puncture; vestiture of moderately abundant, stout, rather short hair. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; bases of interstriae 2–5 armed by a total of about six small submarginal crenulations; striae not impressed, punctures very large, close, deep; interstriae half as wide as striae, smooth, shining, some minute punctures present, tubercles uniseriate, small, sharply pointed on odd-numbered interstriae, very small to absent on even-numbered interstriae of most specimens. Declivity convex, steep; striae and interstriae narrower than on disc; tubercles on interstriae 3, 5, and 7 larger, rather widely spaced; vestiture of ground cover of stout, pointed setae, each about equal in length to width of an interstriae, confused on 2 and 3 to base, sometimes confused on 3 and 4 near base of declivity.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 27-X-1969, No. 93, 2500 m, *Eschweilera*, and 12-I-1970, No. 235, ex liana, SLW.

Biology: Taken from the phloem of a standing, injured tree about 40 cm in diameter.

Notes: The above treatment was based on the type series of 29 specimens.

Phloeotribus subovatus Blandford

Plate XVI

Phloeotribus subovatus Blandford, 1897:167. Lectotype ♂; El Reposo, Guatemala; BMNH, London, designated by Wood (1982:277; References in Wood & Bright c1992:234)

Phloeotribus argentinae Blackman, 1943:386. Holotype ♀; El Que-mado, Argentina; USNM, Washington (References in Wood & Bright c1992:218). *New synonymy*

Diagnosis: Transverse epistomal carina of male short, strongly elevated; pronotum reticulate, asperities normal.

Male: Similar to female except median one-fifth of epistoma armed by a very strongly elevated transverse carina, moderately, broadly concave from carina to upper level of eyes; antennal scape with a large tuft of hair; interstitial setae stouter.

Female: Length 2.0–2.4 mm, 1.8 times as long as wide; color very dark brown to black. Frons narrowly impressed

immediately above epistomal margin, convex from below level of antennal insertion to vertex; surface reticulate, punctures small, obscure; vestiture of fine, sparse, short hair; middle segment of antennal club at least 6 times as wide as long. Pronotum 0.80 times as long as wide; asperities on anterior half, rather numerous, of moderate size; surface reticulate, punctures of irregular size, moderately close, rather deep; vestiture sparse, slender. Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; bases of interstriae 2–5 with a total of about twelve coarse, submarginal crenulations; striae sharply impressed, punctures small, distinct; interstriae twice as wide as striae, shining, with many impressed points, crenulations uniseriate, subacute, rather high, each at least two-thirds as wide as an interstriae, smaller to obsolete by base of declivity. Declivity convex, steep; striae narrower than on disc; interstriae with more impressed points, tubercles reduced in size, very small, distinct; vestiture of uniseriate interstitial rows, each moderately coarse, length equal to half distance between rows, spaced within a row by length of a seta.

Distribution: Guatemala to Argentina.

Argentina: El Quemado [Jujuy].

Venezuela: 20 km SW El Vigia, Merida, 21-XI-1969, 50 m, No. 147, unidentified tree bole, SLW.

Biology: Taken from transverse, biramous parental tunnels in a small, standing, injured tree.

Notes: The above treatment was based on 121 specimens, 3 of which I compared to the lectotype of *Phloeotribus subovatus* Blandford.

Phloeotribus schoenbachii Kirsch

Phloeotribus schoenbachii Kirsch, 1866:214. Holotype ♂; Bogota, Colombia; MNB, Berlin (References in Wood & Bright c1992:232)

Diagnosis: This species is most closely related to *biguttatus* Blandford from which it is easily distinguished by characters summarized in the above key; however, it is more easily confused with the unrelated *picipennis* Eggers and *setulosus* Eichhoff. From *picipennis* and *setulosus* it is distinguished by the much narrower, higher epistomal carina; by the much broader, more extensive male frontal concavity that extends distinctly above the upper level of the eyes; its surface is obscurely, densely micropunctate. It differs from *picipennis* by the pronotum lacking reticulation; by the discal striae that are much more coarsely punctured; and by the longer interstitial setae. It differs from *setulosus* by the much less strongly elevated declivital interstriae 9 ending separately in 3 without first fusing with the costal margin.

Male: Length 2.2 mm, 1.9 times as long as wide; color brown, pronotum darker. Frons with transverse epistomal carina rather strongly elevated on median fourth, its transverse length equal to half width of an eye; broadly (eye to eye), moderately concave from epistoma to distinctly above upper level of eyes; surface of concave area subshining, obscurely, densely micropunctate

(appearing weakly, obscurely subreticulate at less than 80X); elevation on lateral margin at level of antennal insertion with 1 obscure tubercle on its summit; vestiture of sparse, short, inconspicuous hair; scape ornamented by a tuft of long hair. Pronotum about 0.72 times as long as wide (anterior margin broken, part missing); anterior fourth armed by rather small asperities; surface shining, punctures on disc large, irregular; rather deep, becoming somewhat smaller laterally and toward anterior margin; vestiture rather sparse, moderately short, inconspicuous. Elytra 1.2 times as long as wide; 2 submarginal crenulations; about 1.8 times as long as pronotum (estimated); striae moderately, broadly impressed, punctures very coarse, rather deep; interstriae on disc as wide as striae, weakly convex, surface smooth, shining (no impressed points), crenulations uniseriate, subacute, spaced by distance equal to width of an interstriae, about two-thirds as wide as an interstriae at base, half as wide at base of declivity. Declivity broadly convex, steep; striae and interstriae narrower than on disc, crenulations reduced to uniseriate tubercles of rather small size; interstriae 9 moderately elevated, rather finely serrate (much lower and more weakly serrate than in *setulosus*), ending at interstriae 3 without fusing with costal margin. Vestiture of uniseriate rows of erect interstitial setae, setae very slender at base, slightly stouter on declivity, varying from half (base, lower declivity) to two-thirds (base of declivity) as long as distance between rows, spaced within a row from 1.0–1.5 times length of a seta.

Distribution: Colombia: Bogota, Kirsch.

Notes: The above treatment was based on the male holotype from Colombia. This species has been variously misidentified by all authors, except Kirsch, who have reported it from other countries. It is easily confused with *picipennis* (as was done in Wood & Bright c1992:232), *willei* Schedl, and *setulosus*, from which it is easily distinguished by the more broadly, extensively impressed upper male frons.

Phloeotribus biguttatus Blandford

Plate XI

Phloeotribus biguttatus Blandford, 1897:169. Holotype ♂; Bugaba, Chiriqui, Panama; BMNH, London (References in Wood & Bright c1992:219)

Diagnosis: Distinguished from *subovatus* Blandford by the much larger anterior asperities on the pronotum; by the smooth, shining pronotum (between punctures); and by the smaller interstitial crenulations.

Male: Similar to female except frons with an acutely elevated carina on median one-fifth, broadly, deeply concave from carina to well above upper level of eyes, surface finely reticulate, punctures minute, obscure, almost glabrous; antennal scape with a tuft of long hair; pronotal asperities larger, mostly on anterior one-third; interstitial crenulations smaller, bristles stouter, slightly longer.

Female: Length 1.8–2.7 mm, 1.7 times as long as wide; color brown to reddish brown. Frons transversely impressed from epistoma to level of antennal insertion, convex above; surface reticulate, with sparse, shallow punctures of moderate size; middle segment of antennal club about 10 times as wide as long. Pronotum 0.82 times as long as wide; asperities on anterior one-third narrow, large; basal half smooth, shining, some areas of reticulation on anterior half, punctures of moderate size, shallow, most spaced by distances greater than diameter of a puncture; subglabrous except near lateral margins. Elytra 1.05 times as long as wide, 1.4 times as long as pronotum; bases of interstriae 2–5 armed by about six submarginal crenulations; striae moderately, narrowly impressed, punctures small, close, distinct; interstriae three times as wide as striae, smooth, shining, impressed points numerous, obscure, crenulations uniseriate, low, subacute, widest almost half as wide as an interstriae. Declivity convex, steep; striae and interstriae narrower than on disc; interstriae 1–7 each armed by a uniseriate row of small tubercles, 8 with tubercles only at base; 9 acutely, rather strongly elevated and continued to suture, its crest finely serrate.

Distribution: Panama to Colombia and Venezuela.

Colombia: Campo Capote 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 591, *Brosimum*, SLW.

Venezuela: Barancas, Barinas, 1-X-1969, 150 m, No. 32, *Brosimum*, SLW; 8 km SW Bumbum, Barinas, 11-II-1970, 150 m, No. 318, *Brosimum*, SLW.

Biology: Taken from phloem in biramous parental galleries in limbs 4–15 cm in diameter.

Notes: The above treatment was based on 28 specimens from Colombia and on 49 from Venezuela. I compared 3 of the Colombia specimens directly to the holotype of *biguttatus* Blandford.

Phloeotribus ebeneus Wood, n. sp.

Phloeotribus ebeneus Wood: Holotype ♂; Canyon de Lobos, Yauhtepec, Morelos, Mexico; USNM, Washington, designated below

Diagnosis: Distinguished from *biguttatus* Blandford by the slightly larger size and black body color; by the strongly reticulate pronotum disc, with deeper punctures; by the much larger, wider transverse crenulations on the base of the discal interstriae; and by other characters described below.

Male: Length 2.7–3.2 mm, 1.7 times as long as wide; color black. Frons broadly, rather strongly concave from epistoma to slightly above eyes; epistomal margin weakly elevated, with median fifth very strongly elevated, apical margin straight, its lateral angles armed by a pair of small tubercles; concave area more strongly impressed below level of antennal insertions, entire concave area reticulate, punctures above small, with sparse setae on epistoma; antennal scape with a moderate tuft of long setae on apical two-thirds, each segment of club 6 or more times as wide as long. Pronotum 0.85 times as long as wide; sides widest at base, rather strongly, arcu-

ately converging to moderately rounded anterior margin; anterior submargin armed by 10 or more very coarse serrations; summit anterior to middle of pronotum length, anterior slope armed by many serrations; small discal area strongly reticulate, punctures rather coarse, deep; sparse setae on anterior slope. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; disc occupying about 60 percent of elytra length; discal interstriae about one and one-half times as wide as striae (wider on 2 at extreme base); surface smooth, shining, with sparse, minute punctures, and rather coarse crenulations, each about as wide as its interstriae, uniseriate except confused at base of 2. Declivity very steep, convex; interstriae about twice as wide as striae, crenulations replaced on each by a uniseriate row of small tubercles. Vestiture of uniseriate rows of setae, setae slightly shorter and more slender than in *biguttatus*.

Female: Similar to male except frons convex, median epistomal elevation absent.

Mexico (Morelos).

Type material: The male holotype, female allotype, and 10 paratypes were taken at Canyon de Lobos, Yauhtepec, Morelos, Mexico, 22-VII-1983, Martinez & Saucedo. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Phloeotribus asperulus Eggers

Phloeotribus asperulus Eggers, 1943:353. Lectotype ♂; Cochabamba, Bolivia; NHMW, Wien, present designation (References in Wood & Bright c1992:219)

Diagnosis: Distinguished from *willei* Schedl by the smaller punctures on the basal half of the pronotum; by the smaller striae punctures; and by the larger interstitial crenulations on the disc.

Male: Length 1.7 mm, 2.1 times as long as wide; color very dark brown. Frons about as in *willei* except appearing slightly narrower, more strongly impressed above level of antennal insertion, ending above rather abruptly, distinctly below upper level of eyes; scape ornamented by a rather large tuft of very long hair. Pronotum 0.91 times as long as wide; crenulations on anterior half rather coarse (moderately small on anterior margin); basal half smooth, shining, punctures rather coarse, moderately deep; vestiture rather long, moderately abundant. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; striae distinctly impressed, punctures rather coarse, deep; interstriae distinctly wider than striae, smooth, shining, crenulations very coarse (as wide as an interstriae) on basal half of disc, smaller and narrower by base of declivity. Declivity broadly convex, steep; striae and interstriae narrower than on disc; crenulations reduced to rows of moderately coarse tubercles, slightly smaller and more widely spaced on 2, 4, and 6. Vestiture consisting of uniseriate interstitial rows of rather fine setae, each slightly shorter than distance between rows, about equally spaced within a row.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the male syntype that subsequently was incorrectly labeled by Schedl as the "holotype." The other syntype, also a male, was incorrectly labeled by Schedl as the allotype of *asperulus* Eggers. The first of these syntypes is here designated as the lectotype of *Phloeotribus asperulus* Eggers.

Phloeotribus willei Schedl

Phloeotribus willei Schedl, 1937:66. Syntypes, sex?; Lima, Peru; NHMW, Wien, and DEI, Muncheberg (Synonymy and references in Wood & Bright c1992:235)

Phloeotribus chiliensis Eggers, 1942:16. Holotype, sex?; Quillota bei Valparaiso, Chile; Hamburg Museum, lost, Eggers cotype in NHMW, Wien

Diagnosis: Acutely elevated transverse male epistomal carina at least half as wide as epistoma; crest of declivital interstriae 9 ends before joining costal margin, tubercles on all declivital interstriae; body rather slender.

Male: Similar to female except epistomal margin with an acutely elevated transverse carina on slightly less than median half, moderately, broadly concave from carina to upper level of eyes, upper half reticulate and coarsely punctured, lower area smooth and with small obscure punctures, lateral margin at level of antennal insertion armed by 2 small, rounded tubercles (lower one sometimes acutely pointed).

Female: Length 1.8–2.0 mm, 2.2 times as long as wide; color dark brown. Frons transversely impressed from epistoma to level of antennal insertion, convex above; surface reticulate, punctures obscure, fine below, moderately coarse above; vestiture of fine, sparse, moderately long hair; middle segment of antennal club about 6 times as wide as long. Pronotum 0.84 times as long as wide; asperities on anterior half rather coarse; surface smooth, shining, punctures coarse, deep, very close, interspaces equal in width to less than half diameter of a puncture; vestiture of fine, short, sparse hair. Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; bases of interstriae 2–5 with a total of about four submarginal crenulations; striae at base feebly impressed, moderately impressed by base of declivity, punctures coarse, deep, spaced within a row almost by diameter of a puncture; interstriae almost as wide as striae, surface smooth, shining, no impressed points, crenulations uniseriate, subacute, almost as wide as an interstriae. Declivity convex, steep; striae narrower than on disc; tubercles on interstriae 1–3 small, sharply pointed to apex, on 5–8 slightly larger, 9 weakly elevated, more coarsely tuberculate, crest of 9 joining apex of 3, not costal margin (costal margin with about two serrations near suture); vestiture of slender, uniseriate rows of interstitial setae, each as long as distance between rows, spaced within a row by length of a bristle.

Distribution: Chile to Peru.

Chile: Quillota, 9-97; Arapa, Tarapaca, Tarcala 29, 17-IV-68, tronco higuera, R. Charlin C.; Rva P. Tamaruga, I

Region, 1-XI-1993, T. Curkovic; Valle de Azapa, I Region, 3-XI-1993, T. Curkovic.

Peru: Lima, 15-IX-1935, 305-135, Wille.

Host: *Ficus carica*.

Notes: The above treatment was based on 12 males and on 1 female from Chile that are in the Museo Nacional de Historia Natural, Santiago, Chile. The female specimen in the Berlin Museum, compared by Eggers to the type of *schoenbachi* Kirsch, appears to be a specimen of *willei* Schedl.

Phloeotribus contortus Schedl

Phloeotribus contortus Schedl, 1973:167. Holotype ♀; Maturaca on alto Rio Canaburi, Amazonas, Brazil; MZUSP, Sao Paulo (References in Wood & Bright c1992:219)

Diagnosis: Distinguished from *minor* Wood by the reticulation on the pronotum disc; by the less strongly convex discal interstriae; and by the slightly shorter, stouter interstitial setae.

Female: Length 1.3–1.5 mm, 1.8 times as long as wide; color very dark brown, almost black. Frons as in *minor* except more strongly reticulate. Pronotum 0.81 times as long as wide, almost as in *minor* except surface reticulate or reticulate-granulate, punctures on disc much smaller, setae apparently longer. Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; about as in *minor* except discal interstriae less strongly convex, tubercles slightly smaller, setae slightly stouter and shorter.

Distribution: Brazil: Maturaca on alto Rio Cauaburi, Amazonas, 12-17-XII-1962, J. Rechyne.

Notes: The above treatment was based on the female holotype and on 1 female paratype (NHMW, Wien) that is in rather poor condition.

Phloeotribus minor Wood

Phloeotribus minor Wood, 1977:391. Holotype ♂; 27 km NE Montoya, Santander, Colombia; USNM, Washington (References in Wood & Bright c1992:225)

Diagnosis: Body very small; transverse male epistomal carina about half as wide (transversely) as epistoma; declivital interstriae 2 and 4 unarmed by tubercles.

Male: Similar to female except epistoma armed by an acute transverse carina on slightly more than median half, broadly concave from carina to upper level of eyes, surface smooth, shining, impressed points present, punctures not evident; scape bearing a tuft of long hair.

Female: Length 1.3–1.4 mm, 1.8 times as long as wide; color dark brown. Frons convex from epistoma to vertex, surface reticulate, punctures small, of moderate spacing; vestiture of sparse, fine, short hair; middle segment of antennal club about 6 times as wide as long. Pronotum 0.86 times as long as wide; asperities small, rather abundant on more than anterior half; surface shining, punctures rather coarse, deep, spaced by about diameter of a puncture; vestiture of short, moderately abundant, stout setae. Elytra 1.3 times as long as wide, 1.6

times as long as pronotum; bases of interstriae 2–5 armed by a total of about four submarginal crenulations; striae weakly impressed at base, distinctly by base of declivity, punctures coarse, not sharply impressed; interstriae as wide as striae, smooth, shining, a few minute impressed points present, crenulations small, about as wide as interstriae, their posterior face steep, formed by a setiferous puncture. Declivity convex, steep; striae and interstriae narrower than on disc; interstriae 2 and 4 usually unarmed, an occasional minute tubercle present in females only, 5–9 with pointed tubercles, slightly larger on 8 and 9; interstriae 9 not joining costal margin; apical portion of costal margin feebly serrate; vestiture of uniseriate interstitial rows of erect, moderately stout setae, each seta almost as long as distance between rows, spaced within a row by slightly greater distances; setae on interstriae 1 slightly longer.

Distribution: Colombia: 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 601, *Pseudoolmedia*, SLW.

Notes: The above treatment was based on the type series of 38 specimens.

Phloeotribus picipennis Eggers

Phloeotribus picipennis Eggers, 1943:352. Holotype ♂; Cochabamba, Bolivia; USNM, Washington, printed 30 April 1943 (References in Wood & Bright c1992:226)

Phloeotribus boliviae Blackman, 1943:387. Holotype ♀; Mapiri, Bolivia; USNM, Washington, printed 12 October 1943 (References in Wood & Bright c1992:232). *New synonymy*

Diagnosis: Transverse male epistomal carina rather long; crest of elevated interstriae 9 ending at interstriae 3.

Male: Similar to female except epistoma with a subacutely elevated carina on at least median one-half, shallowly concave from carina to midway between level of antennal insertions and upper level of eyes; scape with a tuft of long hair; asperities on pronotum less numerous; often surface of pronotum entirely reticulate.

Female: Length 1.8–2.5 mm, 2.0 times as long as wide; color dark brown, elytra brown. Frons transversely impressed from epistomal margin almost to upper level of antennal insertion, convex from there to vertex; surface reticulate, punctures very small, obscure; vestiture of sparse, fine, short hair; middle segment of antennal club about 10 times as wide as long. Pronotum 0.81 times as long as wide; surface reticulate on anterior half, partly shining and partly reticulate on posterior areas, asperities in lateral areas numerous, rather extensive, punctures moderately large, shallow, spaced by about diameter of a puncture; vestiture of sparse, rather slender, moderately long setae. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; bases of interstriae 2–5 with a total of about nine submarginal crenulations; interstriae moderately impressed, punctures rather small, close, distinct; interstriae twice as wide as striae, surface smooth, shining, crenulations rather small, subacute, almost as wide as an interstriae near base, half as wide near base of declivity. Declivity convex, steep; striae

and interstriae narrower than on disc, striae more strongly impressed, interstriae moderately convex, each bearing a uniseriate row of small, pointed tubercles; interstriae 9 rather weakly elevated, moderately serrate, elevation joining interstriae 3 (not costal margin); vestiture of interstitial rows of erect, slender bristles, each half as long as distance between rows, spaced within a row by twice length of a seta.

Distribution: Colombia to Bolivia and Brazil.

Bolivia: Cochabamba; Mapiri.

Brazil: Rondon; Nova Teutonia, Santa Catarina, X-1956, F. Plaumann.

Colombia: Bogota.

Notes: The above treatment was based on 2 males and 2 females from Brazil. The males were identified as *picipennis* Eggers by Schedl; the females were compared by me to a paratype of *boliviae* Blackman, which had been placed in synonymy with *schoenbachi* Kirsch by Schedl. This species superficially resembles *schoenbachi* but is quite unrelated (see above key).

Phloeotribus remorsus Wood

Plate XIV

Phloeotribus remorsus Wood, 1977:391. Holotype ♂; Piedras Blancas, 10 km E Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:228)

Diagnosis: Distinguished from *transversus* Chapuis by the black color; by the strongly reticulate pronotum; and by the strongly, narrowly elevated declivital interstriae 9.

Male: Similar to female except epistoma with an acutely elevated carina on median half, shallowly concave from carina to well below upper level of eyes; scape with a large tuft of long hair; asperities on pronotum less numerous and narrower; interstitial setae slightly stouter.

Female: Length 2.4–3.0 mm, 1.8 times as long as wide; mature color black. Frons transversely impressed from epistoma almost to upper level of eyes; surface rugose-reticulate (or minutely granular), punctures very small, rather sparse; vestiture of fine, rather short, inconspicuous hair; middle segment of antennal club about 10 times as wide as long. Pronotum 0.80 times as long as wide; surface rugose-reticulate (or minutely granular), asperities in lateral areas extending almost to base, punctures on disc small, obscure; vestiture mostly limited to lateral margins. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; bases of interstriae 2–5 with a total of five submarginal crenulations; striae moderately impressed at base, rather strongly by base of declivity; interstriae twice as wide as striae, moderately convex, surface shining, with many impressed points, crenulations uniseriate, moderately acute, each two-thirds as wide as an interstriae at base, one-third as wide at base of declivity. Declivity convex, rather steep; striae rather deeply impressed, striae and interstriae narrower than on disc, each interstriae with a uniseriate row of

moderately large, pointed tubercles except usually obsolete on lower half of 1 and 2; interstriae 9 strongly, narrowly elevated to suture, basal half rather strongly serrate, weakly serrate near suture; vestiture of erect, rather slender setae, each seta half as long as distance between rows, spaced within a row by about twice length of a seta.

Distribution: Colombia: Piedras Blancas 10 km E Medellin, Antioquia, 15-VII-1970, 2500 m, No. 654, *Quercus humboldtii*, SLW.

Biology: Taken from phloem of a limb 15 cm in diameter, in transverse, biramous parental galleries.

Notes: The above treatment was based on the type series of 81 specimens.

Phloeotribus serratus Eggers

Phloeotribus serratus Eggers, 1943:354. Holotype ♂; Bolivia: Cochabamba; NHMW, Wien (References in Wood & Bright c1992:232)

Diagnosis: Distinguished from male *setulosus* Eichhoff by the presence of tubercles on declivital interstriae 2 and 4; by the very much deeper interstriae; and by the greatly reduced tuft of hair on the male scape.

Male: Length 2.2 mm, 1.9 times as long as wide; color black. Frons as in male *setulosus* (including calluses between antennal insertions); scape with a very small tuft of about a dozen hairs. Pronotum 0.83 times as long as wide; anterior half armed by about 20 narrow, moderately high asperities (about 6 on anterior margin); posterior half smooth, brightly shining, punctures coarse, deep, close; a few long, hairlike setae on anterior and lateral margins. Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; striae strongly impressed except very strongly impressed near and on base of declivity; interstriae about as wide as striae, moderately convex at base, strongly convex on and near base of declivity, moderately convex on declivity. Declivity broadly convex, steep; striae and interstriae narrower than on disc. Vestiture restricted to uniseriate interstitial rows, much longer on posterior two-thirds, longest setae slightly longer than distance between rows, more closely spaced (irregular) within a row.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the male holotype.

Phloeotribus transversus Chapuis

Plate XVI

Phloeotribus transversus Chapuis, 1869:44. Lectotype ♂; Colombia; IRSNB, Brussels, present designation (References in Wood & Bright c1992:235)

Phloeotribus marginatus Eggers, 1933:4. Holotype ♂; Colonia Tovar, Venezuela; NHMW, Wien (References in Wood & Bright c1992:224). *New synonymy*

Diagnosis: Distinguished from *setulosus* Eichhoff by the larger average size; by the more nearly flattened discal interstriae; by the broader scutellum; and by the somewhat stronger male frontal impression.

Male: Similar to female except epistoma with an acutely elevated transverse carina on more than median half, broadly, concavely impressed from carina to well below upper level of eyes; antennal scape with a large tuft of long hair; pronotum mostly smooth, little reticulation; declivital interstriae 2, 4, 6, and 8 largely to entirely devoid of tubercles; interstitial setae shorter.

Female: Length 2.1–2.7 mm, 1.8 times as long as wide; color brown. Frons transversely impressed above epistomal margin to level of antennal insertion, convex above to vertex; surface strongly reticulate, punctures small, shallow, obscure; vestiture of rather sparse, short hair; middle segment of antennal club about 10 times as wide as long. Pronotum 0.80 times as long as wide; asperities in lateral areas extend almost to base; surface reticulate on anterior half, mostly smooth, shining on basal half, punctures mostly on discal area of basal half, of variable size, shape and spacing, sparse and obscure anteriorly; vestiture of rather sparse, fine, moderately long hair. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; bases of interstriae 2–5 with a total of about 10 submarginal crenulations; striae moderately impressed at base, more strongly at base of declivity, punctures coarse, close, confluent on posterior half; interstriae twice as wide as striae, surface smooth, shining, a few obscure points posteriorly, crenulations subacute, almost as wide as an interstriae on basal half, less than one-third as wide at base of declivity. Declivity convex, steep; striae and interstriae narrower than on disc; each interstriae with a uniseriate row of small, pointed tubercles; interstriae 9 strongly, narrowly elevated to suture, its crest coarsely tuberculate except finer near suture; vestiture of uniseriate rows of erect, slender interstitial setae, each seta about two-thirds as long as distance between rows, spaced by similar distances within a row.

Female: Similar to male except frons convex.

Distribution: Colombia to Venezuela.

Colombia: "Colombie."

Venezuela: Colonia Tovar, Aragua, 4-V-1970, 1700 m, No. 504, ex unidentified tree, SLW.

Biology: Taken from transverse parental galleries in phloem of an unidentified tree.

Notes: The above treatment was based on the 3 male and 1 female syntypes of *P. transversus* Chapuis in the Chapuis Collection, on 1 Dejean male (Dresden Museum), and on 86 specimens from Venezuela, 2 males of which I compared to the male syntypes of this species and to the holotype of *P. marginatus* Eggers. The first syntype in the Chapuis series, a male, is here designated as the lectotype of *P. transversus* Chapuis as indicated above.

Phloeotribus setulosus Eichhoff

Plate XV

Phloeotribus setulosus Eichhoff, 1868:149. Lectotype ♂; type labeled "Colombia," published as "Carolina"; IRSNB, Brussels, designated by Wood (1973:182; Synonymy and references in Wood & Bright c1992:232)

- Phloeotribius dubius* Eichhoff, 1868:150. Holotype ♂; Colombia; MNB, Berlin
- Phloeotribius asperatus* Blandford, 1897:166. Holotype ♂; Panajachel, Guatemala; BMNH, London
- Phloeotribius armatus* Blandford, 1897:166. Holotype ♂; Volcan de Chiriqui, Panama; BMNH, London (References and synonymy in Wood & Bright c1992:218). *New synonymy*
- Phloeotribius sodalis* Blandford, 1897:168. Lectotype ♂; Cerro Zunil, Guatemala; BMNH, London, designated by Wood 1974:286
- Phloeotribius spinipennis* Eggers, 1930:168. Holotype ♂; Colombia, probably Colonia Tovar (apparently taken by Moritz near his home); MNB, Berlin
- Phloeotribius bolivianus* Eggers, 1933:5. Holotype ♂; Cochabamba, Bolivia; USNM, Washington
- Phloeotribius atlanticus* Schedl, 1951:81. Holotype ♂; Cuba; NHMW, Wien
- Phloeotribius mixtecus* Bright, 1972:1494. Holotype ♀; 26 miles S Juchatengo, Oaxaca, Mexico; CNCI, Ottawa (Synonymy and references in Wood & Bright c1992:219)

Diagnosis: Distinguished from *transversus* Chapuis by the smaller average size and darker color; by the absence of reticulation on the pronotum; and by the less extensively impressed male frons.

Male: Similar to female except frons slightly more narrowly, less extensively concave, vertex with a few rounded granules; scape with a large tuft of long hair; pronotum without reticulation; declivital interstriae 2, 4, 6, and 8 without tubercles; interstitial bristles slightly longer, stouter.

Female: Length 1.9–2.4 mm, 1.9 times as long as wide; color dark brown, elytra often reddish brown. Frons as in *transversus* except reticulation finer, punctures above coarser, deeper, usually with a few rounded granules; antenna as in *transversus*. Pronotum 0.84 times as long as wide; surface with very limited reticulation on median area of anterior third, punctures coarser, deeper, more regular than in *transversus*. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; as in *transversus* except discal interstriae with numerous impressed points, interstriae 2 and 4 unarmed by tubercles except at base, 6 and 8 with most tubercles absent, interstitial bristles distinctly stouter.

- Distribution: Mexico (Jalisco) to Brazil.
Bolivia: Cochabamba [Woytkowski].
Brazil: Amazon; Bahia, Cepec, Ilheus, II-III-1981, blacklight, Kaston.
Colombia: Campo Capoe 27 km NE Montoya, 2-VII-1970, 150 m, No. 597, ex log, SLW; 8 km S Colonia (near Buenaventura), Valle del Cauca, 9-VII-1970, 30 m, No. 623, *Guarea trichilioides*, SLW; Pisqua, Tona, Santander S., 26-VI-1969, gumo blanco, R. Parra.
Peru: Cited in Wood & Bright c1992:232.
Venezuela: Barrancas, Barinas, 1-X-1969, 150 m, No. 32, *Brosimum*, SLW; 40 km E Canton, Barinas, 3-III-1970, 70 m, No. 396, *Brosimum*, SLW.

Hosts: *Brosimum* spp., *Cedrela mexicana*, *Celtis iguanaea*, *Croton gossypifolius*, *Ficus*, *Guarea trichilioides*.

Biology: Taken from limbs and branches larger than 2 cm in diameter from phloem in transverse, biramous parental galleries. Larval mines followed the grain of the wood.

Notes: The above treatment was based on 1 specimen from Bolivia, 4 from Brazil, 81 from Colombia, and 86 from Venezuela. The lectotype was examined and compared to my series. I examined the holotypes or syntypes of *P. dubius* Eichhoff (by Eggers), *P. asperatus* Blandford, *P. sodalis* Blandford, *P. spinipennis* Eggers, *P. bolivianus* Eggers, and *P. armatus* Blandford and I compared these to my series.

Species Not Seen

Phloeotribius longipilus Eggers

- Phloeotribius longipilus* Eggers, 1943:355. Holotype, sex?; Cochabamba, Bolivia; MNHN, Paris (References in Wood & Bright c1992:224)

Phloeotribius porteri Bruch

- Phloeotribius porteri* Bruch, 1914:25. Syntypes, sex?; Chile (cerca de Concepcion y Santiago); Porter Collection and Bruch Collection (References in Wood & Bright c1992:227)

TRIBE PHLOEOSININI

Description: Frons usually dimorphic, male variously impressed, female flat to convex; eye entire to shallowly emarginate in South American genera; funicle 5- to 7-segmented, club flattened, weakly to very strongly asymmetrical, with or without sutures; pronotum unarmed by asperities in South American genera (except weakly in *Dendrosinus*); tarsal segment 3 laterally compressed to bilobed; scutellum visible or not; metanotum fused to postnotum.

Biology: All known South American species of this tribe are monogynous. Bigyny occurs in 1 Mexican *Chramesus* and polygyny in some *Hyledius* from the Indo-Australian area. All are phloeophagous except for

the xylophagous *Dendrosinus* and at least 3 species of *Chramesus*. Parental tunnels are mostly monoramous and include a conspicuous turning niche or nuptial chamber; a few are unequally (rather primitively) biramous. Eggs are placed in individual niches and are packed in frass. Larval mines tend to follow a definite course that radiates from the parental gallery without crossing one another.

Notes: The South American species that represent this tribe constitute a diverse assemblage of American genera that are rather remotely related to those from the Eastern Hemisphere and, to a lesser extent, to North America.

Key to the Genera of Phloeosinini

- 1. Antennal club symmetrical to weakly asymmetrical; eye emarginate; funicle 6- or 7-segmented; procoxae either separated or contiguous 2
- Antennal club very strongly asymmetrical, sutures strongly procurved when present; eye entire; funicle 5-segmented; procoxae rather widely separated 4
- 2(1). Funicle 7-segmented; bases of elytra each strongly procurved and produced anteriorly resulting in a deep scutellar notch and oblique grooves in posterolateral areas of pronotum for their reception; pronotum armed by asperities (usually minute to rather small); scutellum visible; procoxae very widely separated; body stout, mature color usually black; xylophagous ***Dendrosinus***
- Funicle 6-segmented, club variable; eye emarginate; bases of elytra normal, not abnormally produced or procurved; procoxae moderately separated 3
- 3(2). Antennal club subglobular, sutures obsolete or indicated by sparse setae; pronotum unarmed by asperities; procoxae contiguous; scutellum reduced or not visible; color usually reddish brown; phloeophagous ***Cladoctonus***
- Antennal club flattened, slightly asymmetrical, sutures 1 and 2 clearly marked; pronotum with small clusters of asperities at anterolateral angles; procoxae narrowly separated; scutellum visible; color black; habits unknown ***Cortisinus***
- 4(1). Antennal club with sutures strongly procurved, clearly marked by rows of setae and grooves; phloeophagous ***Pseudochramesus***
- Antennal club without sutures or definite rows of setae; mostly phloeophagous ***Chramesus***

GENUS *DENDROSINUS* CHAPUIS

Dendrosinus Chapuis, 1869:28. Type-species: *Hylesinus globosus* Eichhoff, monobasic

Diagnosis: Antennal funicle 7-segmented, club symmetrical, with 2 sutures on basal half; procoxae very widely separated; pronotum with minute to rather small asperities in anterolateral areas.

Description: Body stout, 1.5–1.7 times as long as wide; mature color black. Frons simple, sexual dimorphism present, obscure; eye elongate, emarginate; antennal funicle 7-segmented, club almost symmetrical, 2 weakly procurved sutures on basal half; pronotum armed by a few asperities in lateral areas, basal margins obliquely grooved and impressed for reception of anteriorly produced basal margins of elytra; elytra with small marginal

and submarginal crenulations, striae narrowly, abruptly impressed, punctures almost obsolete, interstriae wide, almost flat, with short, confused setae, interstriae 1 on right side at least twice as wide as 1 on left side; declivity moderately steep, simple, abdomen rising about half distance to meet apex of elytra; procoxae very widely separated; tarsal segment 3 bilobed.

Distribution: Tropical America. Wood & Bright (c1992: 236–237) list 8 species from Florida (USA) to Argentina.

Biology: The 4 species known to me attack cut or broken tree or liana stems 3–15 cm in diameter where

adult parents make (unequal) somewhat biramous parental galleries in the xylem. Eggs are packed in frass in individual niches. Larvae make long, xylophagous mines that follow the grain of the wood. It is suspected that only 1 generation is produced each year in a wet, tropical environment. In 1 species, *bourreriae* Schwarz, when the infested limb was disturbed, the 100 or more adults burrowing within the limb stridulated rapidly, loudly, and continuously for several minutes, thereby giving the impression that the limb was infested by a swarm of angry bees.

Key to the Species of *Dendrosinus*

- 1. Anterolateral margin of pronotum armed by a paired cluster of 3, narrow, coarse asperities, a second paired cluster of rather coarse asperities in anterolateral area about one-fourth pronotum length from anterior margin; pronotum disc more coarsely, deeply punctured; frons more strongly convex, especially on lower half, median line not marked by a definite crest; Brazil to Paraguay; 3.3–3.5 mm **ater** Eggers
- Anterior margin in lateral areas not armed by asperities, a cluster of small asperities present in anterolateral areas about one-third pronotum length from anterior margin; pronotum disc with punctures rather fine, very shallow; frons more nearly flattened, its median line marked by a definite crest 2
- 2(1). Frons moderately, broadly convex, reticulate median crest (female) or impunctate shining area (male) extending from epistoma to just below upper level of eyes; Argentina and Bolivia to Ecuador and Venezuela; *Brosimum*; 3.6–4.4 mm **globosus** (Eichhoff)
- Frons more nearly flattened in male and with median crest reticulately etched throughout its length, extending from epistoma to well above eyes (one-third of crest above upper level of eyes); Brazil; 3.8–4.6 mm **vittifrons** Blandford

Dendrosinus ater Eggers

Plate XVIII

Dendrosinus ater Eggers, 1930:167. Holotype ♂; published as OstBolivia [Cochabamba, on label of holotype]; USNM, Washington (Synonymy and references in Wood & Bright c1992:236)

Dendrosinus paraguayensis Eggers, 1930:168. Holotype ♀?; Paraguay; USNM, Washington (References in Wood & Bright c1992:237).

New synonymy

Dendrosinus hirsutus Schedl, 1958:38. Lectotype ♀; Santa Fe, Dep. Garay, Argentina; NHMW, Wien, present designation

Diagnosis: Distinguished by the paired clusters of 3 high, slender asperities on the anterolateral margin of the pronotum; by the more strongly convex frons that lacks a median crest.

Female: Length 3.3–3.5 mm, 1.7 times as long as wide; color black. Frons convex from epistoma to vertex, more narrowly protuberant on median one-third about level of ocular emargination; surface subshining, finely, uniformly granulate-punctate, median line not identified by a change in sculpture or vestiture; antennal club 1.4 times as long as wide, sutures moderately procurved. Pronotum 0.81 times as long as wide; surface reticulate, punctures small, very close, moderately deep; vestiture of small, rather

abundant, recumbent hair. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; bases armed by a row of crenulations and numerous small, submarginal crenulations; striae narrowly, abruptly, shallowly impressed, punctures obsolete, reticulate; interstriae three or more times as wide as striae, surface reticulate, with numerous, very small, confused, setiferous crenulations. Declivity convex, moderately steep; sculpture as on disc; vestiture of abundant, short, recumbent, almost hairlike setae, each about equal in length to width of a striae (one-third width of an interstriae), setae golden in specimens examined (mature color?).

Distribution: Argentina and Bolivia to Brazil and Paraguay.

Argentina: Santa Fe, Dep. Garay.

Bolivia: Cochabamba [Woytkowski].

Brazil: Nova Teutonia, Santa Catarina 27°11'S, 52°23'W, 1-X-1963, 300–500 m, F. Plaumann.

Paraguay: "Paraguay."

Notes: The above treatment was based on the female holotype of *ater* Eggers, on 3 females identified by Schedl as *paraguayensis* Eggers, 1 of which I compared directly to the holotype of *ater*, and on the syntype of *hirsutus* that was cited subsequent to the original description

by Schedl (1979:117) as the "holotype." This specimen is here designated as the lectotype of *Dendrosinus hirsutus* Schedl as required under the International Code on Zoological Nomenclature.

Dendrosinus globosus (Eichhoff)

Plate XVIII

Dendrosinus globosus (Eichhoff), 1868:149 (*Hylesinus*). Holotype, sex?; America borealis; Hamburg Museum, lost. Only known surviving syntype (now Holotype ♂, Colombia, taken by Dejean), IRSNB, Brussels (References in Wood & Bright c1992:237)

Diagnosis: Pronotal asperities small, none on anterior margin; median line on frons (smooth, shining in male, elevated and reticulate in female) extending from epistoma to upper level of eyes.

Male: Similar to female except median line on frons smooth, shining, impunctate from epistoma to upper level of eyes.

Female: Length 3.6–4.4 mm, 1.6 times as long as wide; color black. Frons very broadly convex, a weak median crest indicated from epistoma to upper level of eyes; surface reticulate, punctures (including median line) minute, rather dense, sharply impressed, most becoming granulate at level above eyes; vestiture of fine hair, moderately long in lower, lateral areas, shorter toward vertex; 2 sutures on antennal club weakly procurved. Pronotum 0.81 times as long as wide; surface reticulate, strongly reticulate within very shallow, abundant, close, obscure punctures, weakly reticulate on interspaces and median line; asperities in lateral areas minute, none near anterior margin; vestiture of short, recumbent hair. Elytra 1.2 times as long as wide, 1.8 times as long as pronotum; basal margins armed by a row of crenulations, submarginal crenulations small, numerous, gradually transending into interstitial tubercles; striae abruptly, shallowly impressed, reticulate punctures almost obsolete; interstriae reticulate, flat, about three times as wide as striae, setiferous tubercles small, obscurely three-ranked, less numerous than in *ater* Eggers. Declivity convex, moderately steep; sculpture as on disc except striae deeper, interstriae narrower; vestiture of short, dark, stout, moderately abundant setae.

Male: Similar to female except median line on frons smooth, shining, impunctate from epistoma to upper level of eyes.

Distribution: Argentina to Colombia and Venezuela.

Argentina: Cited in Wood & Bright (c1992:236).

Bolivia: Cited in Wood & Bright (c1992:236).

Colombia: "Colombie."

Ecuador: Rio Napo, Aguarito, 20-X-1942, 250 m, Karusterborgh.

Venezuela: 9 km S Barrancas, Barinas, 1-X-1969, 150 m, No. 36, *Brosimum* (and No. 97, *Torrubia*), SLW.

Notes: The above treatment was based on the male holotype of *Hylesinus globosus* Eichhoff and on 1 specimen from Ecuador and 37 from Venezuela. I compared 1 Venezuelan male directly to the Eichhoff syntype at

Brussels. This appears to be the only surviving syntype and, therefore, is here recognized by me as the holotype of *globosus* (Eichhoff).

Dendrosinus vittifrons Blandford

Dendrosinus vittifrons Blandford, 1897:156. Lectotype ♂; Brazil; BMNH, London, present designation (References in Wood & Bright c1992:237)

Diagnosis: Distinguished from *globosus* (Eichhoff) by the weakly elevated median line of the frons (extending from epistoma to vertex, well above eyes) that is reticulately etched throughout its length.

Male: Similar to female except frons more strongly, broadly, irregularly flattened, median crest as in female.

Female: Length 3.8–4.6 mm, 1.6 times as long as wide; color black. Frons very similar to *globosus* except median line more conspicuously elevated from epistoma to vertex (one-third of length of crest above upper level of eyes), crest transversely etched or reticulate throughout its length. Pronotum as in *globosus* except asperities distinctly larger, at least twice as numerous, none of them near anterior margin. Elytra as in *globosus*.

Distribution: Brazil: Guanabara, Rio de Janeiro, X-1963, M. Alvarenga, also #3695 and 1905 #100 by Fry; Rio Santo, Fry; Ilha Santo Amara near Santos, 24-III-1912, G.E. Bryant; Gktt., Brazil, S. America, F.W. Sampson Coll. 1926-482, "C" (male lectotype).

Notes: The above treatment was based on 2 males and 13 females. I compared 1 female to the Blandford syntype at the BMNH, London. Of the 12 specimens under this name at the BMNH, London, on 3 September 1998, specimen #11 is of *D. globosus* (Eichhoff) from Venezuela, #12 is of *D. ater* Eggers (taken by A. Maller). Of the 10 specimens of *D. vittifrons* in the series, most were collected from 1905 to 1912, well after this name was validated. Specimen #7 in this series is a large male (4.6 mm) labeled "S. America, Brazil," mounted on a pin on a microcard; the microcard bears Blandford's handwritten identification "*Dendrosinus vittifrons* Bldf." On the microcard is written "C" (=cotype?), and it bears the Sampson Collection label. It is the only specimen that attains 4.6 mm, the maximum size given by Sampson for the species. This male specimen was obviously a syntype of Blandford and is here designated as the lectotype of *Dendrosinus vittifrons* Blandford.

Species Not Seen

Dendrosinus puncticollis Blandford

Dendrosinus puncticollis Blandford, 1897:156. Holotype, sex?; Colombia; BMNH, London (References in Wood & Bright c1992:237)

Blandford (1897:156–157) described *D. puncticollis* as "Minor fronte subglabra, rudi, supra os modo rugose punctata, et linea media abbreviata notata; oculis antice submarginata; antennis testaceis, clava oblonga, suturis sinuatis; prothorax fortiter conferte punctato, interstitiis nudis, linea media haud distincta; elytris nigro-setosis."

Distribution: Colombia: "Wagner, in Coll. Schaufuss."

Notes: The type was lost with the Hamburg Museum. Eggers (1930:167) in treating *D. ater* states [Halsschild] "Oberseite doppelt so dicht und finer aber deutlich punctiert wie *D. puncticollis* Bldf." Apparently allied to *ater*, but distinct. Its true identity must await the rediscovery of this species.

GENUS *CORTISINUS* WOOD, n. gen.

Cortisinus Wood: Type-species: *Sternobothrus lobatus* Eggers, monobasic

Diagnosis: This genus keys to *Phloeosinopsoides* in Wood (1986:50–51), but is distinguished by the 6-segmented antennal funicle; by the restriction of pronotal asperities to the anterolateral angles; by the different body form; and by numerous other characters described below.

Description: Male frons impressed. Eye oval, one-fourth divided by an emargination. Antennal scape comparatively short; funicle 6-segmented, distinctly longer than scape; club elongate-oval, flattened, with 2 weakly oblique sutures (1 on basal fourth, 2 at middle), apex moderately rounded. Precoxal prosternum rounded, with no indication of a carina. Pronotum with anterolateral angles armed by small clusters of rather small asperities; posterior margin projecting slightly into moderate scutellar notch. Scutellum convex, circular in outline. Setae on pronotum and elytra sparse, hairlike. Tibiae not visible on type specimen of type-species.

Distribution: Only 1 species is known. There are no known closely related genera of Phloeosinini in South America.

Cortisinus lobatus (Eggers), n. comb.

Cortisinus lobatus (Eggers), 1943:374 (*Sternobothrus*). Holotype ♂; Cochabamba, Bolivia; NHMW, Wien (References in Wood & Bright c1992:216)

Diagnosis: This species is unique in the Phloeosinini. It is distinguished by the antenna; by the small patches of crenulations on the anterolateral angles of the pronotum; by the acutely costate median carina on the basal half of the pronotum; and by other characters described below.

Male: Length 2.4 mm, 1.9 times as long as wide; color black. Frons with a rather strong, subacute transverse carina on median half about one-fourth distance below upper level of eyes toward epistoma; area below carina broadly, shallowly concave, surface apparently smooth, shining, with fine, sparse punctures, several rather coarse, moderately long setae just below carina; area from carina to vertex rugose-reticulate, sparse, minute punctures obscure. Eye elongate-oval, clearly emarginate to depth of one-fourth width of eye. Antennal scape rather short, stout (capable of attaining level of posterior margin of eye), with a small tuft of about 6–8 long, yellow, hairlike

setae; funicle slightly longer than scape, 6-segmented; club elongate-oval, about 2.0 times as long as wide, its apex somewhat broadly rounded, sutures 1 and 2 septate, weakly oblique, 2 at middle, 1 on basal one-fourth. Precoxal prosternum rounded (no indication of a carina). Protibia not visible due to glue, etc. Pronotum 0.90 times as long as wide; very broadly rounded in front, projecting behind modestly into scutellar notch; anterolateral angles not projecting, armed on each side by about 5 small crenulations; median line on posterior half subacutely, narrowly costate; surface dull, on posterior half closely covered by enormous, shallow punctures (a few on disc confluent), their centers reticulate, very narrow crests between punctures smooth, shining, anterior one-third somewhat similarly sculptured except width greatly reduced to less than half, a pair of rather widely spaced, weakly subvulcanate pores (mycetangia?) about one-sixth of pronotum length from anterior margin. Scutellum convex, circular in outline, subrugosely punctured; scutellar notch rather deep. Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; basal margins slightly elevated, armed by an obscure row of connected crenulations, submarginal crenulations obscure on interstriae 2; striae abruptly, rather deeply impressed, punctures obsolete, surface minutely granulate; interstriae as wide as striae, moderately convex, punctures uniseriate, rather small, anterior margin of each elevated, finely subcrenulate, surface apparently, minutely granulate (or possibly reticulate, not clean on type). Declivity broadly convex, rather steep; striae punctures very small, obscure, interstriae each with a row of small tubercles (serrate), 3–9 distinctly, not strongly elevated; costal margin near apex slightly flanged outward, margin subseriate. Vestiture confined to declivity (due to abrasion?); minute striae hair present on all striae to middle of disc, interstriae with erect, slender bristles, each two-thirds as long as distance between rows spaced within a row by about length of a bristle.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Biology: Probably attracted to light.

Notes: The above treatment was based on the male holotype.

GENUS *CLADOCTONUS* STROHMEYER

Cladoctonus Strohmeyer, 1911:17. Type-species: *Cladoctonus affinis* Strohmeyer, monobasic (Synonymy and references in Wood & Bright c1992:237–239)

Hoplites Eggers, 1923:140. Type-species: *Hoplites banosus* Eggers, monobasic, preoccupied by Dejean 1833:150

Hoplitontus Wood, 1961:2. Type-species: *Hoplites banosus* Eggers, automatic, replacement name for *Hoplites* Eggers

Hoplitophthorus Wood, 1961:2. Type-species: *Hoplitophthorus sentosus* Wood = *Hoplites interruptus* Eggers, original designation

Diagnosis: Antennal funicle 6-segmented in South American species, club symmetrical, subglobular, sutures partly to entirely obsolete; procoxae contiguous; scutellum visible or not.

Description: Body elongate-oval, color yellowish to reddish brown; frons weakly, sexually dimorphic, male weakly impressed, female convex; antennal funicle 6-segmented, club subglobular, sutures obsolete except obscurely indicated by sparse setae; procoxae contiguous, pronotum unarmed by asperities; scutellum minute to not visible; crenulations on basal margins of elytra much wider than normal; stria punctures impressed, interstriae brightly shining; declivity rather

abrupt, very steep, subvertical on lower half; sparse vestiture always hairlike; tarsal segment 3 slender.

Distribution: Wood & Bright (c1992:237–239) report 6 species from Africa, 1 from the Philippine Islands, 1 from New Guinea, and 7 from tropical America, 4 of which occur in South America.

Biology: They are phloeophagous in a variety of host trees.

Key to the Species of *Cladoctonus*

- 1. Serrated crest of declivital interstriae 9 ending without curving toward or joining costal margin; declivital interstriae 2 armed by pointed tubercles at least on basal portion; upper half of female frons smooth, shining, impunctate 2
- Serrated crest of declivital interstriae 9 curving toward and joining crest of costal margin at level of apex of interstriae 3; declivital interstriae 2 unarmed by tubercles at base or on face of declivity; upper half of female frons punctured 3
- 2(1). Strial punctures on disc small, interstriae wider than striae; body more slender, 2.5 times as long as wide; female frons on lower half transversely impressed, conspicuously protuberant on upper half; Colombia to Bolivia and Brazil; *Pseudoolmedia*; 1.8–2.0 mm *corumbensis* (Eggers)
- Punctures on posterior half of striae 1–3 on disc very large, with almost no interstriae; body stouter, 2.2 times as long as wide; female frons conspicuously, transversely impressed below or protuberant above; Brazil (Mato Grosso); 1.5–1.8 mm *atrocis* Wood
- 3(1). Strial punctures very coarse on disc, interstriae about half as wide as striae; declivital interstriae 1 armed by about nine tubercles throughout its length, 2 armed at base by one or two small tubercles; Colombia; *Citrus aurantium*; 2.1–2.3 mm *interruptus* (Eggers)
- Strial punctures moderately large, very close, regularly spaced, interstriae as wide as striae; declivital interstriae 1 mostly unarmed, about two small tubercles on lower half, 2 entirely unarmed 4
- 4(3). Strial and interstitial punctures in regular rows from base to base of declivity; tubercles on declivital interstriae 9 comparatively small; Mexico (Campeche); *Brosimum*; 1.5–1.8 mm *americanus* Wood
- Strial and interstitial punctures normal on basal half of disc, on posterior half of disc stria punctures lost between large, acutely rounded, shining nodules, three to four nodules present on striae 7, 8 unarmed, 9 with a row of about nine rather large, pointed denticles to its apex near suture; nodules end at base of declivity and normal stria punctures reappear, interstriae 1 and 3 each with a row of about four small, widely spaced denticles; Bolivia; at light; 2.2 mm *tuberculatus* Schedl

Cladoctonus corumbensis (Eggers)

Plate XIX

Cladoctonus corumbensis (Eggers), 1951:149 (*Hoplites*). Holotype, sex?; Corumba, Mato Grosso, Brazil; NHMW, Wien (Synonymy and references in Wood & Bright c1992:238)

Hoplitophthorus boliviae Wood, 1961:106. Holotype ♀; route between Boyuibe to Charagua via Cueva, Ingri, etc., Bolivia; USNM, Washington

Diagnosis: Elevated crest of declivital interstriae 9 not joined to costal margin near suture; stria punctures on disc rather small, interstriae as wide as striae.

Male: Similar to female except frons evenly convex and uniformly rather coarsely punctured, setae short, sparse, except longer at epistomal margin.

Female: Length 1.8–2.0 mm, 2.5 times as long as wide; color yellowish brown to reddish brown. Frons broadly,

moderately, transversely impressed on lower half, surface finely, rather closely punctured, upper half rather strongly convex (protuberant) to above eyes, median half impunctate, brightly shining, marginal areas with a few small punctures; glabrous above, lower area with moderately abundant, fine, long hair. Pronotum 1.0 times as long as wide; surface smooth, brightly shining, punctures rather coarse, close, deep, interspaces averaging half as wide as diameter of a puncture; glabrous. Elytra 1.9 times as long as wide, 2.1 times as long as pronotum; row of crenulations on basal margins of elytra low, poorly formed, bases of interstriae 5 and 6 with combined total of two to three submarginal crenulations; striae feebly impressed, punctures rather small, close; interstriae as wide as striae, smooth, shining, glabrous, punctures small, uniseriate. Declivity short, very steep, lower half vertical or even undercutting toward apex; interstriae 1–7 and 9 armed by pointed tubercles, almost obsolete on lower half of 1, 9 ends at level of 5 without continuation; vestiture of sparse, uniseriate, slender, rather short bristles on declivity, glabrous on disc.

Distribution: Colombia to Bolivia and Brazil.

Bolivia: Route Boyuibe to Chagua via Cueva, Ingri, etc., 15-VII-1-IX-1920, G.L. Harrington.

Brazil: Corumba, Mato Grosso.

Colombia: Campo Capote 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 601, *Pseudoolmedia*, SLW.

Notes: The above treatment was based on 2 paratypes of *boliviae* Wood and on 51 specimens from Colombia. The holotype of *Hoplites corumbensis* Eggers was compared to my series from Bolivia and Colombia.

Cladoctonus atrocis Wood

Cladoctonus atrocis Wood, 1974:12. Holotype ♂; 260 km N Xantavia, Mato Grosso, Brazil; BMNH, London (References in Wood & Bright c1992:238)

Diagnosis: Elevated crest of interstriae not joined to costal margin near suture; strial punctures on disc very large, interstriae half as wide as striae.

Male: Similar to female except lower third of frons moderately, transversely impressed, upper area coarsely, uniformly punctured (without an impunctate area).

Female: Length 1.5–1.8 mm, 2.2 times as long as wide; color reddish brown. Frons convex from immediately above epistoma to well above eyes, less than lower one-fourth with fine punctures, median three-fourths of upper area brightly shining, impunctate, a few punctures on marginal areas; vestiture on lower fourth and on lateral areas near eyes of rather short, coarse setae. Pronotum 0.90 times as long as wide; surface smooth, shining, punctures coarse, deep, rather close, some interspaces equal in width to diameter of a puncture; almost glabrous. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; a row of submarginal crenulations behind marginal row; striae not impressed, punctures at base moderately large, becoming very large from middle of disc to base

of declivity; interstriae smooth, shining, on posterior half of disc less than half as wide as striae. Declivity convex, very steep, vertical on lower half; strial punctures moderately small, interstitial punctures of about equal size; interstriae 1 and 3–9 each armed by a row of pointed tubercles, 2 with two or three tubercles at base of declivity and unarmed below; vestiture restricted to declivity, of sparse, uniseriate rows of fine, moderately long hair.

Distribution: Brazil: 260 km N Xantavia, Mato Grosso, 18-25-X-1968, R.A. Beaver.

Notes: The above treatment was based on 8 paratypes.

Cladoctonus interruptus (Eggers)

Plate XIX

Cladoctonus interruptus (Eggers), 1940:126 (*Hoplites*). Holotype, sex?; Guadeloupe; Fleuteaux Collection, cotype in NHMW, Wien (Synonymy and references in Wood & Bright c1992:239)
Hoplithophorus sentus Wood, 1961:3. Holotype ♂; La Cuchilla, Sevilla, Colombia; USNM, Washington

Diagnosis: Elevated crest of interstriae 9 joining costal margin before sutural apex; declivital interstriae 2 unarmed by tubercles except at base; strial punctures very large on posterior half of disc.

Male: Sexual differences not evident in specimens at hand.

Female: Length 2.1–2.3 mm, 2.2 times as long as wide; color reddish brown. Frons from epistoma to upper level of eyes moderately, transversely impressed, convex above; surface uniformly punctured by rather small, moderately close punctures; vestiture very short, sparse. Pronotum 0.90 times as long as wide; surface brightly shining, punctures coarse, deep, rather close, width of interspaces equal to slightly less than diameter of a puncture; almost glabrous. Elytra 1.8 times as long as wide, 2.0 times as long as pronotum; basal area of elytra with about 6 submarginal crenulations behind marginal row; striae not impressed, punctures very coarse, moderately close; interstriae half as wide as striae, smooth, shining, each with a uniseriate row of small punctures. Declivity convex, very steep; apex undercutting mid-declivity; strial punctures rather small; interstriae 2 and 8 narrow, almost obsolete below, 1, 2, 5, 7, and 9 each armed by a row of fine, pointed tubercles, 2 with one or two tubercles at base; vestiture confined to declivity, of sparse, uniseriate rows of short hair, absent on 2, 6, and 8.

Distribution: Guadeloupe Island and Colombia.

Colombia: La Cuchilla, 19-VI-1959, naranjo seco, J.H. Lasso.

Hosts: *Citrus aurantium*.

Notes: The above treatment was based on the type series of 6 specimens.

Cladoctonus tuberculatus Schedl

Cladoctonus tuberculatus Schedl, 1973:369. Holotype, sex?; Guayamerin, Beni, Bolivia; NHMB, Budapest (References in Wood & Bright c1992:239)

Diagnosis: Distinguished by the very different sculpture as described below.

Male (?): Length 2.2 mm, 2.1 times as long as wide; color reddish brown. Frons convex, a weak, transverse impression below level of antennal insertion; surface smooth, shining, except reticulate at vertex, punctures moderately coarse, rather close, shallow; vestiture of sparse, short, inconspicuous hair. Pronotum 0.91 times as long as wide; surface smooth, shining, punctures rather deep, moderately close, coarse on basal one-third, distinctly smaller on anterior one-third; almost glabrous. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; striae not impressed, punctures coarse, deep on almost basal half of disc; interstriae distinctly narrower than striae on basal half of disc, smooth, shining, minute punctures almost uniseriate; striae 1-7 on posterior half of disc to base of declivity armed on each by about four large, narrowly rounded nodules, punctures between nodules virtually obliterated. Declivity steep, convex, striae punctures almost normal, slightly smaller than on anterior disc, interstriae slightly narrower than striae, 2, 4-8 each with a row of fine punctures, 1 and 3 each with a sparse row of fine tubercles, 9 with a row of about nine coarse denticles extending from apex to level of metacoxae; 9 joining apical margin about level of interstriae 3. Glabrous except for sparse rows of short, stout setae on odd-numbered declivital interstriae.

Distribution: Bolivia: Guayaranerin, Beni, from River Balogh, Mahunka, ZICSI, 18-XI-1966, at light, Soil Zoological Exp.

Notes: The above treatment was based on the holotype, presumably a male.

GENUS *PSEUDOCHRAMESUS* BLACKMAN

Pseudochramesus Blackman, 1939:87. Type-species: *Chramesus acuteclavatus* Hagedorn, original designation

Diagnosis: This genus is distinguished from the closely allied *Chramesus* by the strongly procurved, clearly marked sutures on the antennal club.

Description: Body very stout. Frons sexually dimorphic, female convex to shallowly concave on median half, male broadly, rather strongly concave or with antennal insertions either normal or displaced mesad and dorsad; eye entire; antennal insertions normal or displaced in male, scape elongate, funicle 5-segmented, club strongly asymmetrical, with 2 strongly procurved sutures clearly marked. Pronotum either unarmed or armed only by small granules; procoxae widely separated; scutellum visible; elytral sculpture simple.

Biology: Apparently all species are phloeophagous and monogynous.

Notes: This genus is confined to neotropical areas. Wood & Bright (c1992:261-262) list 11 species, 10 of which occur in South America and 1 in Mexico (Jalisco).

Key to the Species of *Pseudochramesus*

- 1. Interstriae each with a central row of erect scales on disc, each scale in row short, except in *acuteclavatus*, less than twice as long as ground scales, ground scales pale to variegated; male frons broadly concave, its margins on upper half ornamented by a row of very long setae; male antennal insertion normal, near base of mandible 2
- Central row of erect interstitial setae with each seta more slender, often much longer, ground scales broad, recumbent, almost black; male frons modified, narrower above, not broadly impressed, antennal insertions slightly to strongly displaced mesad and dorsad, upper margins without a dense fringe of long setae, area between inner margin of eye and lateral margin of frons with a conspicuous groove 5
- 2(1). Strial punctures on basal half of disc very coarse, deep, striae as wide as interstriae near base; male interstriae 7 on declivity distinctly elevated from near base to junction with 3, apex of 3 briefly elevated at junction with 7 (in male, female normal); Argentina to Bolivia; 1.5-1.6 mm *costulatus* Blackman
- Strial punctures not larger on basal half of disc, interstriae conspicuously wider than striae; male interstriae 7 not conspicuously elevated 3
- 3(2). Interstitial and pronotal setae forming a pattern of dark and pale setae; strial punctures larger, not as close, interstriae slightly less than twice as wide as striae; interstriae on disc without distinct tubercles; Argentina and Brazil to Bolivia; *Peptadinia*; 1.3-1.6 mm ... *acutecravatus*
(H a g e d o r n)
- Interstitial setae essentially unicolorous; strial punctures smaller, deeper, closer; interstriae at least twice as wide as striae; erect setiferous punctures on discal interstriae with a small tubercle at their base 4
- 4(3). Erect setae at base of elytra not longer and almost as stout as those on declivity; declivital interstriae

- Erect setae on basal half of elytral disc longer, very slender; declivital interstriae 2 devoid of tubercles; Brazil (Santa Catarina); 1.5–1.6 mm *duplosquamosus* Schedl
- 5(1). Strial punctures on disc coarse, deep; interstriae as wide as striae; Argentina; 1.7 mm *vianai* Schedl
- Strial punctures small, close, rather shallow; interstriae more than twice as wide as striae 6
- 6(5). Pronotum dull, surface strongly rugose-reticulate, anterolateral areas of male subasperate; interstitial scales apparently obsolete, surface closely granulate, granules moderately coarse, isolated from one another, confused from base to apex, central row of erect setae present, each seta two to four times as long as wide, pale; Brazil; 1.6 mm *brasiliensis* Schedl
- Pronotum weakly to moderately reticulate; interstitial scales present, granules absent except for central row on each interstriae 7
- 7(6). Pronotum mostly shining, sparsely reticulate in anterior areas; each interstriae with a uniseriate row of tubercles; ground setae on disc present 8
- Pronotum clearly reticulate from base to anterior margin, punctures very fine, abundant; discal interstriae punctured, without a central row of tubercles on each; interstitial ground scales apparently obsolete 9
- 8(7). Median line at base of pronotum not impressed, punctures on disc smaller, more numerous; Paraguay; 1.7 mm *golbachi* Wood
- Median line on basal one-fifth of pronotum narrowly impressed, shining, punctures on disc larger, less numerous; Brazil (Santa Catarina); 1.3–1.5 mm *setifer* Schedl
- 9(7). Erect interstitial setae on disc longer, more slender, at least eight times as long as wide, equal in length to two-thirds distance between rows; pronotal punctures smaller, stoutest setae more slender, longer; male not seen; Bolivia; 1.9–2.1 mm *manni* Blackman
- Erect interstitial setae on disc shorter, stouter, each seta four to six times as long as wide, equal in length to less than half distance between rows; pronotal punctures distinctly larger, stoutest setae shorter; male frons with antennal insertions strongly displaced mesad, upper frons very narrow, almost half normal width; Brazil (Mato Grosso); 1.7 mm *opacus* Schedl

Pseudochramesus costulatus Blackman

Pseudochramesus costulatus Blackman, 1939:91. Holotype ♂; Boyuibe to Charagua, Bolivia; USNM, Washington (References in Wood & Bright c1992:262)

Diagnosis: Interstitial ground scales pale; male frons broadly concave; strial punctures at base of disc very coarse, deep; male declivital interstriae 7 moderately elevated.

Male: Similar to female except frons broadly, rather deeply concave from epistoma to vertex, surface subreticulate, upper margins ornamented by long, yellow hair, tips of setae extending below epistoma.

Female: Length 1.5–1.6 mm, 1.4 times as long as wide; color very dark brown, posterior three-fourths of elytra brown to pale brown, vestiture pale. Frons distinctly elevated at level of antennal insertion, rather broadly, shallowly concave from elevation to upper level of eyes; surface subreticulate, margin with setiferous granules;

vestiture at margins, coarse, moderately abundant, rather short. Pronotum about 0.71 times as long as wide; surface reticulate, setiferous punctures small, rather close; vestiture of coarse, rather short, mostly recumbent hair, longer in lateral areas. Elytra 1.04 times as long as wide; striae slightly impressed, punctures rather large, impressed; interstriae twice as wide as striae, surface apparently smooth, punctures small, largely concealed by scales, minute granules at base of erect bristles. Declivity somewhat gradual, beginning anterior to middle, convex, moderately steep; interstriae 2 weakly impressed on lower half; a row of fine tubercles on interstriae 3, 5, 7, and 9 extending to lower half. Ground vestiture of small pale scales, each slightly longer than wide and about one-fifth as wide as an interstriae; erect bristles in central interstitial rows, very short, each about twice as long as wide, about one-fourth as long as distance between rows, spaced within a row by about twice length of a bristle.

Distribution: Argentina to Bolivia.

Argentina: Santa Clara to Jujuy, 23-IX-1921; Palmar to Jujuy, 25-VIII-1921.

Bolivia: Boyuibe to Charagua via Cueva, 15-VII-1-IX-1920; Camatindi, 20-III-1922; Monteaguido, Rio Azero, 1920; Tacuari, 19-VIII-1923, G.L. Harrington.

Notes: The above treatment was based on 1 male paratype and 1 female paratype.

Pseudochramesus harringtoni Blackman

Pseudochramesus harringtoni Blackman, 1939:93. Holotype ♂; Aguio, Bolivia; USNM, Washington (Synonymy and references in Wood & Bright c1992:262)

Pseudochramesus multiseriatus Schedl, 1978:296. Holotype ♀; Tablillas Salta, Argentina; NHMW, Wien

Diagnosis: Interstitial scales pale, unicolorous; striae punctures rather small.

Male: Similar to female except frons about as in male *costulatus* Blackman.

Female: Length 1.4–1.6 mm, 1.6 times as long as wide; color dark brown, interstitial ground setae brown, erect bristles mostly pale. Frons broadly convex from epistoma to vertex; surface obscurely reticulate, obscure punctures fine, moderately close in marginal areas; vestiture of short, rather coarse, moderately abundant setae. Pronotum 0.70 times as long as wide; rather finely subasperate in anterolateral areas; surface strongly reticulate, setiferous punctures rather shallow, moderately close; vestiture of coarse, short, recumbent setae, slightly longer in lateral areas. Elytra 1.06 times as long as wide; striae not impressed, punctures moderately coarse, rather strongly impressed; interstriae almost twice as wide as striae, smooth, shining, punctures small, bristle-bearing punctures finely granulate. Declivity beginning before middle of elytra length, convex, moderately steep; about as on disc except interstriae 2 constricted on lower half (with only one row of scales). Vestiture of ground cover of short scales, each as long as wide, pale along suture, brown elsewhere, pale erect bristles each about four times as long as wide, equal in length to almost half distance between rows, spaced within a row by about 1.5 times length of a bristle.

Distribution: Bolivia: Aguio, 4-X-1920; Boyuibe, 10-X-1920, G.L. Harrington; Guarío, X-1923; San Esteban, 9 km N Santa Cruz, 7-XII-1950, 1120 feet, R. Cumming; Yagacua.

Notes: The above treatment was based on 2 males and 1 female from San Esteban. I compared 1 male directly to the holotype.

Pseudochramesus duplosquamosus Schedl

Pseudochramesus duplosquamosus Schedl, 1963:215. Holotype ♀; Rio Caraguata, Mato Grosso, Brazil; NHMW, Wien (References in Wood & Bright c1992:262)

Diagnosis: Female distinguished from *harringtoni* Blackman by the much more slender, erect interstitial

setae; and by the absence of tubercles on declivital interstriae 2.

Female: Length 1.5–1.6 mm, 1.5 times as long as wide; color almost black. Frons and pronotum as in female *harringtoni*. Elytra as in female *harringtoni* except erect setae on basal half of elytral disc (interstriae 1–5) distinctly longer and much more slender; declivital interstriae 2 without any tubercles (minute tubercles *harringtoni*).

Distribution: Brazil: Rio Caraguata, Mato Grosso, III-1953, F. Plaumann.

Notes: The above treatment was based on the female holotype and on 1 female paratype of *duplosquamosus* Schedl, both from Brazil.

Pseudochramesus acuteclavatus (Hagedorn)

Plate XX

Pseudochramesus acuteclavatus (Hagedorn), 1909:742 (*Chramesus*). Holotype, sex?; La Plata, Argentina; Hamburg Museum, lost (References in Wood & Bright c1992:262)

Chramesus semibrunneus Eggers, 1951:145. Holotype ♀; Brazil; USNM, Washington (References in Wood & Bright c1992:262). *New synonymy*

Diagnosis: Scales on pronotum and interstriae forming a pattern of dark and pale setae; without distinct interstitial tubercles.

Male: Similar to female except male frons as in *harringtoni* Blackman.

Female: Length 1.3–1.6 mm, 1.4 times as long as wide; color very dark brown, vestiture of abundant pale and dark scales and bristles, usually forming a pattern (occasionally entirely pale). Frons broadly convex, a weak elevation at level of antennal insertion, a feeble median impression on upper area; surface coarsely reticulate above, apparently becoming obscurely punctured below (concealed by vestiture); vestiture of rather coarse, short, moderately abundant setae from epistoma to vertex. Pronotum 0.71 times as long as wide; as in *harringtoni* Blackman. Elytra 1.03 times as long as wide; striae distinctly impressed, punctures small, distinct; interstriae two to three times as wide as striae, surface smooth, shining, punctures very small, confused, bristle-bearing punctures uniseriate, tuberculate. Declivity beginning before middle, convex, moderately steep; about as on disc, interstriae 2 constricted, 3 joins 9 (not elevated), 1, 3, 5, and 7 each with a uniseriate row of minute tubercles. Vestiture of ground cover of scales, each scale as wide as long, about one-fourth as wide as an interstriae, erect bristles each two to four times as long as wide, about one and one-half times as long as ground scales; scales usually forming a pattern of dark and pale areas.

Male: Similar to female except frons as in *harringtoni*.

Distribution: Argentina and Bolivia to Paraguay.

Argentina: Aguaray; La Plata; Salta-Oran, Abra Grande, I-III-1967, R. Golbach; Tartagal.

Bolivia: Buena Vista: Camatindi; Tacuari; Tarija, Inge Bermejo, R. Golbach; Tigulpa; Villa Montes; Yagacua, IV-1924, G.L. Harrington.

Brazil: Brasilien im rinde von *Peptadina*.

Paraguay: Carumbe, Dep. San Pedro, I-1971, R. Golbach.

Notes: The above treatment was based on the female holotype of *semibrunneus* (Eggers), on 6 specimens from Argentina identified by Blackman prior to the loss of the holotype of *acuteclavatus*, on 9 from Bolivia, and on 17 from Paraguay.

Pseudochramesus vianai Schedl

Pseudochramesus vianai Schedl, 1958:39. Syntypes ♂ ♀; Tigre, Buenos Aires, Argentina; NHMW, Wien and Viana Collection (References in Wood & Bright c1992:262)

Diagnosis: Interstitial ground scales black; punctures on pronotum rather coarse, deep, close; striae punctures on disc coarse, deep, interstriae as wide as striae.

Female: Length 1.7 mm, 1.6 times as long as wide; color black, ground scales dark brown to black, erect bristles pale. Frons not visible in specimen at hand. Pronotum 0.70 times as long as wide; surface shining, punctures rather coarse, moderately deep, very close, interspaces mostly equal in width to less than half diameter of a puncture, (smooth?). Elytra 1.08 times as long as wide; striae not impressed on disc, moderately on declivity, punctures coarse, deep, close; interstriae as wide as striae, minute punctures obscure, erect bristles arise from posterior margin of weakly subcrenulate tubercle. Declivity beginning at middle of declivity length, convex, moderately steep; interstriae twice as wide as striae, 2 constricted toward apex. Vestiture of ground cover of short, stout scales each as wide as long; interstitial scales apparently replaced by tubercles on lower declivity.

Distribution: Argentina: Tigre, Buenos Aires, I-1951, M.J. Viana.

Hosts: *Acacia cavenia* (Bright & Skidmore 2002:38).

Notes: The above treatment was based on 1 female paratype.

Pseudochramesus brasiliensis Schedl

Pseudochramesus brasiliensis Schedl, 1948:265. Syntypes ♀ [probably a ♂]; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien and Plaumann Collection (References in Wood & Bright c1992:262)

Diagnosis: Pronotum dull, surface rugose-reticulate, interstitial ground scales apparently obsolete, apparently replaced by abundant, confused, rather coarse granules.

Male: Length 1.4–1.6 mm, about 1.6 times as long as wide; color black. Frons moderately, rather broadly concave from epistoma to upper level of eyes, concave area rugose-reticulate, vestiture abraded; insertion of antenna displaced only slightly dorsad and mesad. Pronotum (damaged) about 0.70 times as long as wide; several small asperities in lateral and anterior areas, surface dull, rugose-reticulate, punctures obscure; vestiture coarse, short, rather sparse, longer in lateral areas. Elytra about 1.1 (spread) times as long as wide; striae impressed,

punctures small, obscure; interstriae three to four times as wide as striae, dull, densely covered by moderately large, closely set, confused granules. Declivity beginning near middle of elytra length, convex, steep; sculpture as on disc, interstriae 2 constricted only slightly on lower half. Vestiture of ground cover of black scales (when light in one position, appearing as tubercles when light in a different position); erect bristles in rows, each seta stout (each 2–4 times as long as wide, short, length equal to less than one-third distance between rows).

Female: Similar to male except frons weakly convex.

Distribution: Brazil: Rondon, Nova Teutonia, 25-XI-1952, 500 m, F. Plaumann; Santa Fe do Sul, Sao Paulo, 17-IX-2003, Recando das Aguas Claras, degraded riparian forest fragment, ex bark of dying *Platypodium elegans*, C.A.H. Flechtmann.

Notes: The above treatment was based on 2 males, 1 of which I had compared to the Schedl syntype, and on 1 male and 8 additional female specimens.

Pseudochramesus golbachi Wood, n. sp.

Pseudochramesus golbachi Wood: Holotype ♀; Carumbe, Dep. San Pedro, Paraguay; USNM, Washington, designated below

Diagnosis: Interstitial scales black; erect interstitial bristles short; pronotum weakly reticulate and punctures deep, numerous.

Female: Length 1.7 mm, 1.6 times as long as wide; color almost black. Frons shallowly concave on median half from epistoma to upper level of eyes; surface reticulate, with rather sparse granules on margins of upper half; vestiture coarse, moderately long, rather abundant. Pronotum 0.74 times as long as wide; weakly, rather obscurely reticulate, shining, punctures small, moderately deep, rather close; vestiture somewhat coarse, rather short, moderately abundant. Elytra 1.2 times as long as wide; about as in *manni* Blackman except tubercles in interstitial rows distinctly larger, erect interstitial bristles short, about as in *opacus* Schedl.

Distribution: Paraguay: Dept. San Pedro, Carumbe, I-1971, R. Golbach.

Notes: The above treatment was based on the female holotype.

Pseudochramesus setifer Schedl

Pseudochramesus setifer Schedl, 1951:93. Holotype ♀; Cachoeirinha-Una, Bahia, Brazil; NHMW, Wien (References in Wood & Bright c1992:262)

Pseudochramesus abbreviatus Schedl, 1951:94. Lectotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, designated below (References in Wood & Bright c1992:261). *New synonymy*

Diagnosis: This species is distinguished by the small size; by the shining discal area of the pronotum; and by the presence of rows of interstitial tubercles.

Male: Length 1.3–1.5 mm, 1.5 times as long as wide; color black, ground setae dark, erect setae pale. Frons broadly, moderately concave from epistoma to upper

level of eyes; surface shining, subreticulate (more strongly above); vestiture of rather long, coarse setae, sparse in central area, more numerous on lateral margins. Pronotum 0.71 times as long as wide; surface shining, irregularly subreticulate and shallowly, rather densely punctured on posterior half, anterior half with small setiferous tubercles; median line on basal one-fifth narrowly, weakly impressed; vestiture coarse, rather short, of moderate abundance. Elytra 1.0 times as long as wide, 1.6 times as long as pronotum; striae weakly impressed, punctures small, deep, close; interstriae twice as wide as striae, surface smooth, shining, a row of very small punctures on both right and left margins, and a central row of small tubercles, tubercles spaced by distances less than width of an interstriae. Declivity on slightly less than posterior half, convex, steep; sculpture about as on disc except striae punctures more widely spaced; vestiture of ground cover of dark scales, each very slightly longer than wide and erect setae arising from tubercles, of pale color, each about four to six times as long as wide, length equal to half distance between rows, spaced within a row by slightly less than length of a scale.

Female: Similar to male except frons broadly convex, surface finely subrugose.

Distribution: Brazil: Chachoeirinha-Una, Bahia (holotype of *setifer* Schedl); Nova Teutonia, VIII-1941 (lectotype of *abbreviatus* Schedl), X-1941, F. Plaumann.

Notes: The above treatment was based on the female holotype of *setifer*, on the male holotype, female allotype, and 2 paratypes (1 male, 1 female) of *abbreviatus* Schedl, and on 3 other specimens from Schedl's series of *setifer*. The third specimen in Schedl's series of *setifer* is a glue-covered male of what appears to be *costulatus* Blackman. Because Schedl's subsequent designation of a holotype is invalid, I here designate his "holotype" as the lectotype of *P. abbreviatus* Schedl.

Pseudochramesus manni Blackman

Pseudochramesus manni Blackman, 1939:88. Holotype ♀; Beni River below Riberalta, Bolivia; USNM, Washington (References in Wood & Bright c1992:262)

Diagnosis: Interstitial ground scales black; erect pale bristles two-thirds as long as distance between rows.

Female: Length 1.9–2.1 mm, 1.6 times as long as wide; color black, scales along elytral suture pale. Frons essentially convex, a slight median impression from just above level of antennal insertion to just below upper level of eyes; surface finely rugose-reticulate above, more nearly reticulate below; vestiture mostly on margins, coarse, moderately abundant, rather long. Pronotum 0.80 times as long as wide; surface reticulate, punctures fine, deep, rather close; vestiture mostly fine, recumbent, rather short, longer in lateral areas; asperities sparse, minute to absent. Elytra 1.2 times as long as wide; striae moderately impressed, punctures rather small, shallow, distinct; interstriae distinctly convex, shining, punctures dense, rather fine, bristle-bearing punctures feebly tuber-

culate on declivity. Declivity beginning at middle of elytra length; convex, rather steep; interstriae narrower than on disc, punctures strongly confused. Vestiture of ground cover of short, obscure scales and erect, slender bristles, each bristle half (laterally) to three-fourths (mesally) as long as distance between rows.

Distribution: Bolivia: Cachueta Esperanza, Beni [Beni River below Riberalta].

Notes: The above treatment was based on 1 female paratype.

Pseudochramesus opacus Schedl

Pseudochramesus opacus Schedl, 1963:216. Syntypes ♂; Rio Caraguata, Mato Grosso, Brazil; NHMW, Wien and Plaumann Collections (References in Wood & Bright c1992:262)

Diagnosis: Interstitial ground scales black; erect bristles in central interstitial rows short; pronotum rather strongly reticulate.

Male: Length 1.7 mm, 1.5 times as long as wide; color black. Frons shallowly impressed on lower half, more strongly above; surface reticulate, vestiture sparse; antennal insertions displaced dorsad (almost to upper level of eyes) and mesad, separated above by half width at epistoma; a rather strong, glabrous groove between margin of frons and margin of eye (wide above, narrow below). Pronotum 0.75 times as long as wide; surface strongly reticulate, punctures small, shallow, most setiferous punctures associated with a fine granule, moderately close; vestiture rather coarse, short, moderately abundant. Elytra 1.2 times as long as wide; about as in *manni* Blackman except interstitial punctures distinctly smaller, erect interstitial bristles all short, each less than half as long as distance between rows.

Distribution: Brazil: Mato Grosso, Rio Caraguata, 2-III-1953, F. Plaumann.

Notes: The above treatment was based on 1 male paratype of *opacus* Blackman. Bright & Skidmore (1997:59) record the host as *Apuleia molaris*, these specimens were not seen by me.

GENUS *CHRAMESUS* LeCONTE

Chramesus LeConte, 1868:168. Type-species: *Chramesus hickoriae* LeConte, monobasic (Synonymy and references in Wood & Bright c1992:262–270)

Rhopalopleurus Chapuis, 1869:146. Type-species: *Rhopalopleurus tuberculatus* Chapuis, subsequent designation by Hopkins 1914:128

Thaumasinus Reitter, 1913:39. Type-species: *Dendrosinus bonnairei* Reitter = *Rhopalopleurus rotundatus* Chapuis, monobasic

Prochramesus Wood, 1956:254. Type-species: *Prochramesus annectans* Wood, original designation

Diagnosis: Antennal club strongly asymmetrical and unmarked by sutures; antennal funicle 5-segmented; eye entire; procoxae widely separated.

Description: Male frons weakly to strongly concave, female convex; antennal funicle 5-segmented, club strongly flattened, strongly asymmetrical, unmarked by sutures or rows of setae; eye elongate, entire. Procoxae

widely separated; pronotum smooth to reticulate, with fine to moderately coarse punctures, anterior areas unarmed to finely to moderately asperate, more finely asperate in male. Scutellum present, minute. Crenulations on basal margins of elytra usually conspicuous; striae clearly indicated, impressed in some species, punctures coarse to fine or rarely obsolete; interstriae weakly convex, vestiture usually of confused ground cover of scales or hair, and rows of erect bristles; variegated pattern of pale and dark scales in some species.

Distribution: Wood & Bright (c1992:262–270) report 89 species from North and South America, 41 of which were from South America.

Biology: Except for 1 bigynous species in Mexico (*incomptus* Wood), the species are monogynous and

mostly phloeophagous. One myelophagous (*quadridens* Wood) and 3 xylophagous species occur in Mexico. The female forms the entrance tunnel and turning niche. The 1 (rarely 2) egg gallery formed by the female may be longitudinal, oblique, or transverse. It is usually in the cambium area. Eggs are deposited in individual niches packed in frass. Larval mines radiate from the parent tunnel without crossing one another. Initially they are mostly in the phloem but engrave the wood rather deeply as they mature. Most species breed in stems less than 5 cm in diameter, although one was taken from a tree bole 20–30 cm in diameter. Several species breed in lianas where, occasionally, the entire stem beneath the bark may be consumed.

Key to the Species of *Chramesus*

- 1. Male frons broadly, rather deeply concave, its lateral margins variously acute to well above level of antennal insertion, often with multiple subtuberculate elevations at or above level of antennal insertions; most species with scales, never with spines 2
- Male frons broadly, shallowly to rather deeply concave, its lateral margins armed at or below (one exception has declivital spines) level of antennal insertion by only 1, pointed denticle (displaced slightly mesad in 1 species; poorly formed in one species); either interstitial setae hairlike or declivity armed by spines in most species 30
- 2(1). Lateral margin of male frons variously sculptured, from a simple crest to a low, subquadrate elevation or (3 species) a double tubercle on lower third (to slightly above level of antennal insertion) 3
- Lateral margins of male frons acutely elevated above level of antennal insertion to one-third to two-thirds of distance to upper level of eyes, its crest (usually) beaded by 5 or more indentations (obscure in some *phloeotriboides*) 19
- 3(2). Lateral margin of male frons a simple crest with no denticles or distinctly quadrate elevations at level of antennal insertion 4
- Lateral margin of male frons armed at level of antennal insertion by either 2 pair of small denticles or a (usually) low, subquadrate elevation 10
- 4(3). Epistomal margin on male marked by an obtuse crest; body slender, 2.1 times as long as wide, color dark brown to black; strial punctures obscure, almost obsolete; interstitial ground setae and erect setae slender, hairlike; Venezuela; native bamboo; 2.0–2.5 mm *simplicis* Wood
- Smaller species; body stouter, 1.8 times as long as wide, color pale brown; strial punctures rather strongly impressed, normal; interstitial ground setae and erect bristles short, strongly flattened 5
- 5(4). Male frons with a small denticle on lateral margin at level of antennal insertions; interstitial ground setae on declivity little longer than wide, erect setae three times as long as ground setae, each six times as long as wide, their length equal to half distance between rows; Costa Rica to Venezuela; *Acacia*; 1.5–1.8 mm *acacicolens* Wood
- Lateral margin of male frons unarmed; erect interstitial setae much shorter, each less than four times as long as wide 6
- 6(5). Male frons with epistomal margin subacutely to acutely elevated on median third; interstitial setae in ground cover slender, each seta at least twice as long as wide 7

- Male frons with epistomal margin rounded, not elevated; interstitial setae in ground cover stout, each about as long as wide 9
- 7(6). Male frons shallowly concave; discal striae not impressed, interstitial tubercles minute to obsolete; eyes greatly enlarged, narrowly separated above by less than width of an eye; body 2.1 times as long as wide; Brazil (Santa Catarina); 1.4–1.5 mm **neglectus** Schedl
- Male frons rather deeply, broadly concave; discal striae distinctly, abruptly impressed, interstitial tubercles acute, distinct, in regular rows; eyes normal for this genus, separated above by at least twice width of an eye; body 1.8 times as long as wide 8
- 8(7). Male frons less deeply, less extensively excavated, not attaining margin of eyes, epistoma subacute, not elevated; pronotum reticulate; ground vestiture on pronotum and elytra slender, less abundant, each seta at least four times as long as wide; Costa Rica to Venezuela; *Bauhinia* liana; 1.3–1.4 mm **denticulatus** Wood
- Male frons more deeply, more extensively excavated, impression reaching inner margin of eye, epistomal margin strongly, acutely elevated; pronotum surface smooth, shining; ground vestiture on pronotum and elytra scalelike, each seta about as wide as long; Brazil (Mato Grosso); 1.3 mm **minor** Eggers
- 9(6). Interstitial ground setae distinctly larger, about half as long as erect setae; setae on anterior margin of pronotum much longer and more slender than on disc; Brazil; 1.4–1.6 mm **asperulus** Schedl
- Interstitial ground setae smaller, shorter, erect setae much more slender but only slightly longer than ground setae; setae on anterior margin of pronotum short, as on disc; Mexico (Oaxaca) to Honduras; Leguminosae sp.; 1.2–1.3 mm **minulus** Wood
- 10(3). Elevation on lateral margin of male frons restricted to one area on lower half 11
- Elevation on lateral margin of male frons divided into a blunt, subquadrate tubercle below level of antennal insertion and a conspicuous, acute longitudinal carina on upper third to just below upper level of eye (see also *striatus* Eggers) 18
- 11(10). Predominant area of elevation on lateral margin of male frons at and below level of antennal insertion 12
- Predominant area of elevation on lateral margin of male frons at and above level of antennal insertion 16
- 12(11). Lateral margins of male frons armed by 2 pair of tubercles at level of antennal insertion; pronotum dull, reticulate only on anterior third; interstitial ground cover of minute scales, each scale as wide as long, less than one-fourth as long as an erect seta; Mexico (Jalisco) to Panama; *Canavalia*, *Phaseolus*; 1.4–2.0 mm **pumilus** (Chapuis)
- Lateral margin of male frons armed by an obscure, subquadrate denticle at and below level of antennal insertion; interstitial ground setae larger, at least one-third as long as erect setae 13
- 13(12). Male frons very shallowly impressed on median half, ending well below upper level of eyes; interstitial ground setae more slender (but rather coarse), mostly six or more times as long as wide, erect setae shorter than in *aspericollis*, each seta equal in length to less than half distance between rows; pronotum mostly smooth, shining, anterior area with limited reticulation; Brazil; 1.4–1.7 mm **aberrans** Schedl
- Male frons rather strongly, broadly concave; interstitial ground setae stout, only slightly longer than wide, erect setae longer, each about two-thirds as long as distance between rows; pronotum strongly reticulate throughout, rather dull 14

- 14(13). Strial punctures on disc extremely minute to obsolete; interstriae five times as wide as striae; impression on male frons extending slightly above upper level of eyes; Argentina; 1.8 mm *ovalis* Schedl
- Strial punctures on disc rather small, impressed to obsolete, interstriae about two to five times as wide as striae; impression on male frons ending slightly below upper level of eyes 15
- 15(14). Disc of pronotum rugose-reticulate; discal striae distinctly impressed, most strial punctures impressed (few obsolete); interstriae three to five times as wide as striae, distinctly convex; ground setae on disc more numerous, each about two to four times as long as wide; Argentina to Brazil (Santa Catarina); 1.5–1.8 mm *aspericollis* Schedl
- Disc of pronotum weakly reticulate; discal striae not impressed, strial punctures mostly near base, minute to obsolete behind, interstriae about five times as wide as striae; discal setae on interstriae more slender, ground setae mostly four to six times as long as wide; Brazil (Santa Catarina); 1.9 mm *setiger* Schedl
- 16(10). Elevation on lateral margin of male frons with its summit rounded, male epistomal margin armed by an acutely elevated carina on median two-thirds; interstitial ground setae absent; Venezuela; *Phoradendron*; 2.2–2.4 mm *priscus* Wood
- Elevation on lateral margin of male frons acute; male epistomal margin not armed by a transverse carina; interstitial ground scales present 17
- 17(16). Strial punctures clearly, regularly, closely impressed; setae on upper half of male frons much finer; asperities on lateral areas of pronotum smaller, less numerous; Venezuela; “Bejuco trinitaria”; 1.6–1.9 mm *orinocensis* Wood
- Strial punctures minute to obsolete, widely spaced; setae on upper half of male frons rather coarse; asperities on lateral areas of pronotum distinctly larger, more numerous; Venezuela; unidentified liana; 1.9–2.1 mm *vinealis* Wood
- 18(10). Lateral margin of male frons with elevation below level of antennal insertion and with crest slightly elevated, narrowly rounded; interstitial setae without low ground cover; Venezuela; *Brownia*; 1.8–2.1 mm *impolitus* Wood
- Lateral margin of male frons with elevation below level of antennal insertion more acutely rounded, more nearly resembling a tubercle; scalelike interstitial ground setae present; Venezuela; “pelito del cruz” and tree seedling; 1.8–2.3 mm (see also *striatus* Eggers, no male for comparison) *imporcatus* Wood
- 19(2). Male antennal club more slender, 2.2 times (2.0 in *granulipennis*) as long as wide, scape ornamented by fewer than a dozen setae, mostly shorter, about half as long as scape; pronotum shining to weakly reticulate; larger species 20
- Male antennal club stouter, 2.0 times as long as wide, scape ornamented by a tuft of yellow hair of more than a dozen setae, most longer than scape; pronotum more strongly reticulate; smaller species 28a
- 20(19). Male frons deeply concave, its lateral margins above level of antennal insertions acutely elevated and marked on crest by about 16 beads from upper level of eyes two-thirds distance toward level of antennal insertion, an elevated, blunt tubercle on margin below level of antennal insertion; pronotum reticulate, dull; discal interstriae 1–5 armed by rows of large, rounded tubercles (each as high as wide), uniseriate on 1 and 3–5, biseriate on 2 anterior to declivity then uniseriate on declivity; Brazil (Parana); 2.1 mm *granulipennis* Schedl
- Male frons deeply concave, lateral margins with beaded crest at level of antennal insertions, extending dorsad part of distance toward upper level of eyes; interstriae with tubercles or crenulations smaller or transversely crenulate 21

SCOLYTIDAE OF SOUTH AMERICA

- 21(20). Crest of lateral margin of male frons feebly, irregularly subserrate; discal interstriae with ground setae absent (present and scalelike on declivity) or very slender, erect setae very slender, almost hairlike 22
- Crest of lateral margin of male frons closely, regularly beaded; discal interstriae with ground setae scalelike (very slender near base on 1 species) 25
- 22(21). Interstitial ground setae on disc and declivity of numerous rather broad scales (each about four times as long as wide at base, as long as wide on declivity); crest on lateral margin of male frons obscurely serrate, subdentately terminating abruptly at its dorsal end; Peru; 3.2 mm *peruanus* Schedl
- Interstitial ground vestiture either absent or very slender; lateral crest on male frons terminating gradually above 23
- 23(22). Interstitial ground setae on disc forming a single row on each side of an interstriae, each seta as slender as those in central row, slightly shorter on declivity, each about four times as long as wide; surface of pronotum rather strongly reticulate, asperities not evident; Argentina; 1.7–1.8 mm *advena* Schedl
- Interstitial ground setae on disc essentially absent; declivity with short, scalelike ground setae, each about twice as long as wide 24
- 24(23). Pronotum weakly reticulate, mostly shining, punctures on disc clearly impressed, without any indication of tubercles, anterior and lateral areas with sparse, minute tubercles; discal striae weakly impressed, interstitial tubercles small, confused, erect interstitial setae on margins near base of declivity longer, much coarser; Argentina; 2.3 mm *phloeotriboides* Schedl
- Pronotum strongly reticulate, dull, all punctures associated with or replaced by small, rounded tubercles; discal striae more strongly impressed; interstitial crenulations larger, mostly uniseriate; erect setae on sides near declivity much finer, shorter; Bolivia (Cochabamba); 2.8 mm *granulatus* (Eggers)
- 25(21). Male discal interstriae armed by conspicuous tubercles at base of each erect seta (in central row); surface of pronotum disc reticulate, punctures smaller, not close 26
- Male discal interstriae without a tubercle at base of each erect seta; disc of pronotum shining 27
- 26(25). Male declivital interstriae with ground scales on 4 confused, erect setae present on lower half; Colombia; 1.7 mm *luteus* Wood
- Male declivital interstriae with ground scales on 4 uniseriate, erect setae absent on at least lower half; Venezuela (Merida); tree seedlings; 1.9–2.3 mm *strigilis* Wood
- 27(25). Interstitial ground setae pale, rather sparse and slender on disc, each six or more times as long as wide, scalelike on declivity; discal punctures on pronotum very small, shallow, moderately close; Argentina; 2.0 mm *argentinae* Wood
- Interstitial ground setae forming a variegated pattern of about 50 percent pale and 50 percent dark scales, each scale only slightly longer than wide; punctures on pronotum disc larger, deeper, closer; Argentina to Uruguay; unidentified wood; 2.0–2.2 mm *globosus* Hagedorn
- 28a(19). Male frons shallowly, broadly impressed, feebly if at all concave, impression ending well below upper level of eyes, crest of lateral margin ornamented by about 7 “beads”; male striae much more deeply impressed, punctures almost obsolete; erect interstitial bristles present on declivital interstriae 2 28b
- Male frons deeply concave to upper level of eyes, lateral margin more strongly, acutely elevated, beaded design obscure, more irregularly, finely subserrate 29

PHLOEOSININI

- 28b(28a). Male frons less strongly impressed, lateral margins more weakly elevated; tuft of setae on male scape greatly reduced; setae on pronotum and elytra longer, apparently more abundant; erect interstitial setae on disc two-thirds as long as distance between rows, slender ground setae two-thirds as long as slender erect setae; Bolivia; at light; 2.1 mm *bolivianus* Schedl
- Male frons moderately impressed, lateral margins more strongly, acutely elevated; tuft of setae on male scape prominent; setae on pronotum and elytra shorter; erect interstitial setae not more than half as long as distance between rows, stout (almost scalelike) ground setae about one-third as long as stouter erect setae; strial punctures very close, almost obsolete in some places; Venezuela; liana; 1.4–1.6 mm *solicitatus* Wood
- 29(28a). Pronotum reticulate, without crenulations on anterior slope, punctures uniformly very small; erect interstitial setae about half as long as distance between rows; Brazil (Mato Grosso); 1.6 mm *brasiliensis* Nunberg
- Pronotum reticulate, anterior two-thirds of pronotum armed by numerous subcrenulate tubercles, shallow punctures on disc larger; erect interstitial setae more widely spaced within a row, each about as long as distance between rows, except absent on declivital interstriae 2; Venezuela; liana; 1.3–1.4 mm *peniculus* Wood
- 30(1). Male elytral declivity either unarmed by spines or largest spines on interstriae 3, smaller spines sometimes on 4 (and 5 in one species) 31
- Interstriae 2 on male elytral declivity armed by several coarse spines, smaller spines in female (and sometimes on interstriae 3, etc.) 39
- 31(30). Elytral setae almost scalelike, short interstitial ground cover abundant, subplumose, erect setae stout; tubercle on lateral area of male frons near antennal insertion displaced slightly mesad from lateral margin at level slightly above level of antennal insertions; Brazil; 1.2–1.3 mm *badius* Schedl
- Elytral setae slender, of fine or coarse hair (ground setae sometimes scalelike); tubercle in lateral area of male frons on crest of elevation at level of antennal insertion (very weak in *tuberculatus*) 32
- 32(31). Elytral setae all in uniseriate rows, each an erect, blunt bristle about two-thirds as long as distance between rows; male frontal concavity moderately deep, ending below upper level of eyes, tubercle on lateral margin at antennal insertion rather small; Venezuela; *Tabebuia*; 1.3–1.4 mm *parcus* Wood
- Elytral setae of fine, often semirecumbent hair; male frons concave to above upper level of eyes, a tubercle at or below level of antennal insertion 33
- 33(32). Male frons rather shallowly concave to upper level of eyes, lateral margins rather broadly rounded above level of antennal insertions, slightly elevated below level of antennal insertions into a blunt, obscure tubercle; most declivital setae in uniseriate rows; eyes normal, not enlarged; Argentina; 1.7 mm *cylindricus* Schedl
- Male frons deeply concave to upper level of eyes or above, with a conspicuous spine at level of antennal insertions; most declivital setae confused; larger species 34
- 34(33). Lateral margin of male frons at or below level of antennal insertion with a very large denticle; frons deeply, broadly concave from epistoma to well above eyes; elytral declivity never armed by spines 35
- Tubercle at lateral margin of male frons either below level of antennal insertion or small almost absent; elytral declivity with spines or tubercles in both sexes 36
- 35(34). Striae and strial punctures clearly impressed on disc and declivity; declivity with setae fine, short, much more abundant; Venezuela; native bamboo; 2.2–2.5 mm *macrocornis* Wood

- Striae and stria punctures very weakly impressed on disc and declivity; eyes moderately enlarged; declivital setae much less abundant, slightly coarser; Brazil (Santa Catarina); native bamboo (?); 2.6–2.7 mm (male not seen) *hylurgoides* Schedl
- 36(34). Male frons rather narrowly, rather deeply concave from epistoma to well above upper level of eyes, spine at level of antennal insertion apparently almost absent; declivital interstriae 3 armed by one very large, curved spine near middle of declivity; interstitial ground setae scalelike; Colombia; *Passiflora mollissima*; 1.9–2.1 mm *bispinus* Wood
- Male frons shallowly, broadly impressed from epistoma to not more than slightly above upper level of eyes, tubercle at lateral margin small, below level of antennal insertion; declivital interstriae 3 armed by three or more small to moderately large spines in male, by small tubercles in female; all elytral setae hairlike 37
- 37(36). Male frons with lateral margins above level of antennal insertions rounded, concavity rather shallow on its upper half; male elytral declivity steeper, slightly narrower, interstriae 3 armed by three to five small to moderately large spines, by small tubercles in female; ground setae on elytra of fine hair; Ecuador; flower stalk of Bromeliaceae; 1.9–2.0 mm *dentellus* Wood
- Male frons more strongly impressed above to upper level of eyes, lateral margins subacute from level of antennal insertion about two-thirds distance to upper level of eyes; male declivity moderately steep, more strongly, more broadly sulcate, interstriae 3 armed by six to nine denticles (smaller denticles in lateral areas), female not seen 38
- 38(37). Male declivity with denticles on interstriae 3 rather small, subacutely pointed, not higher than basal width of spine, those on 4 and 5 slightly smaller, absent on 6 to 9; discal interstriae about three times as wide as striae; frons mostly shining, punctures distinct, more numerous; Colombia; 3.5 mm *subtuberculatus* Eggers
- Male declivity with denticles on interstriae conspicuously larger (especially below), smaller denticles on 4 to 9; discal interstriae about one and one-half times as wide as striae; frons more strongly reticulate, punctures sparse, obscure; Colombia; 2.3–2.6 mm *tuberculatus* (Chapuis)
- 39(30). Declivital interstriae 1 unarmed in by spines in male, 2 armed by a row of very large, pointed spines, 3 and 4 similarly armed but spines half as large as those on 2, these spines also present in female but half as large; lateral margin of male frons armed by a large spine slightly above level of antennal insertions; Brazil (Santa Catarina); 2.4–2.5 mm *erinaceus* Schedl
- Declivital interstriae 1 unarmed in male by spines, 2 armed by a row of very large, pointed spines, 3 unarmed by tubercles, 4 armed by a row of spines each half as large as those on 2; lateral margin of male frons armed by a small tubercle at level of antennal insertion 40
- 40(39). Male declivital interstriae 2 armed by a row of eight or nine very large, basally separate, sharply pointed spines, each spine about equal in length to width of an interstriae, 4 and 6 armed by rows of smaller spines; Argentina to Brazil (Santa Catarina); 1.8–2.2 mm *spinosus* Brethes
- Declivital interstriae 2 armed by a row of fourteen to fifteen very large, basally contiguous, obtusely pointed spines; 3 and 5–7 unarmed, 4 with about five pointed denticles at its apex; Brazil (Santa Catarina); 2.3–2.5 mm *phloeosinites* Schedl

Chramesus variegatus Eggers

Chramesus variegatus Eggers, 1943:345. Holotype ♀; Cochabamba, Bolivia; NHMW, Wien (References in Wood & Bright c1992:270)

Diagnosis: This species is not in the above key. It was named from a unique female. It is distinguished by the dark and pale variegated color pattern of setae on the

elytra. The very slender ground setae and erect setae of the elytra and the conspicuous constriction just behind the anterior margin of the pronotum suggest that it is very primitive. It cannot be correctly placed until the male is found.

Female: Length 3.0 mm, 1.9 times as long as wide; color very dark reddish brown; vestiture of a variegated

dark and pale pattern described below. Frons broadly convex, upper two-thirds rugose and rather roughly punctured and weakly tuberculate. Epistoma transversely impressed to level of antennal insertions; vestiture hairlike, short, sparse, except longer and more numerous on epistomal margin; antennal club largely concealed but clearly of *Chramesus* type. Pronotum 0.79 times as long as wide; widest at base, sides on basal half moderately arcuate and converging toward a conspicuous constriction just behind anterior margin; surface broadly convex, small asperities only in lateral areas, most of surface obscurely punctate-granulate; vestiture short, a mixture of slender hair and stouter, semirecumbent bristles of moderate abundance; color pattern not evident on type. Elytra 1.35 times as long as wide, 2.1 times as long as pronotum; disc occupying basal two-thirds; about 24 small, submarginal crenulations behind basal row; striae weakly impressed, punctures very strongly impressed; interstriae almost twice as wide as striae, rather finely, irregularly (confused) crenulate, and with numerous small punctures. Declivity broadly convex, very steep; striae and interstriae narrower than on declivity; striae punctures smaller, not as deep; interstitial crenulations obsolete on lower two-thirds. Vestiture of abundant ground setae, very slender on disc and half as long as erect setae, on declivity of short scales each as long as wide and a third as long as erect setae, erect setae mostly obscure on basal half, in indistinct rows behind, rather stout; a dark brown transverse band of setae on basal fourth of declivity, lower central declivity pale, basal half of disc dark brown, a pale transverse band anterior to base of declivity.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the female holotype from Bolivia.

Chramesus argentinensis Schedl

Chramesus argentinensis Schedl, 1952:456. Lectotype ♀; Isla Martin, Buenos Aires, Argentina; NHMW, Wien, present designation (References in Wood & Bright c1992:263)

Diagnosis: This species is not in the above key. Distinguishing features include the small size; the rugose-reticulate frons and pronotum; and the stout elytral ground setae with slender erect interstitial setae. A male is required for correct placement.

Female: Length 1.25 mm (holotype 1.25 mm, 1.4–1.5 mm in 2 doubtful females), 1.6 times as long as wide; color almost black, vestiture pale. Frons convex, a weak transverse impression at middle; upper half finely rugose-reticulate, apparently smoother and almost shining on lower half; punctures minute; upper half finely rugose-reticulate, apparently smoother and almost shining on lower half; punctures minute, obscure; vestiture sparse, hairlike. Pronotum 0.71 times as long as wide; surface rugose-reticulate; asperities on median third rather small, in lateral (subdorsal) areas asperities coarser, at least part of them forming transversely elongate rugae;

a few small punctures near base at median line; vestiture half of fine, slender, rather short hair; half of stout bristles (each about 10 times as long as wide); crenulations at anterolateral angles rather near margin. Elytra 0.95 times as long as wide, 1.4 times as long as pronotum; disc occupying less than basal half; base with about 7 submarginal crenulations behind basal row; striae weakly impressed, punctures rather large, deep; interstriae less than twice as wide as striae, surface smooth, shining, punctures minute, rather numerous, each with a central row of minute tubercles. Declivity broadly convex, steep; striae narrower than on disc, punctures smaller, poorly formed; interstriae about as wide as striae, tubercles apparently obsolete. Vestiture of ground cover of small, abundant scales, each scale slightly longer than wide, and rows of erect, slender bristles, each about three times as long as ground setae.

Distribution: Argentina: Isla Martin Garcia, Buenos Aires, IV-1938, M.J. Viana (type); Misiones, Dep. Concep., Sta Maria, V-1960, M.J. Viana.

Hosts: *Celtis spinosa* (Bright & Skidmore 2002:39).

Notes: The above treatment was prepared from the female "holotype" of Schedl, actually a syntype; other females (Misiones) in very poor condition were placed here, probably correctly, by Schedl. Because this species was clearly based on a syntypic series, I here designate Schedl's female syntype (his "holotype") as the lectotype of *Chramesus argentinensis* Schedl.

Chramesus corumbensis Eggers

Chramesus corumbensis Eggers, 1951:145. Holotype ♀; Corumba, Mato Grosso, Brazil; NHMW, Wien (References in Wood & Bright c1992:264)

Diagnosis: This species is not in above key. Distinguished by the small size; by the absence of tubercles and asperities on the pronotum; by the large stria punctures; and by the similarity of slender ground cover and erect setae on the interstriae. A male is required for proper placement.

Female: Length 1.4 mm, 1.8 times as long as wide; color very dark brown, vestiture pale. Frons convex above, somewhat flattened below, epistoma weakly elevated; surface reticulate, punctures small, obscure (not fully visible on type). Pronotum 0.72 times as long as wide; surface mostly reticulate; punctures rather small, shallow, moderately close, some punctures in lateral areas replaced by sparse, minute asperities; vestiture of moderately sparse, rather short, slender setae. Elytra 1.2 times as long as wide, 1.8 times as long as pronotum; about 6 submarginal crenulations behind basal row; striae not impressed, punctures large, deep; interstriae as wide as striae, surface smooth, shining, punctures at margins small, each interstriae with a central row of pointed tubercles (small at base, larger toward declivity). Declivity rather strongly convex, steep; striae and interstriae slightly narrower than on disc, interstitial tubercles on lower half distinctly smaller than at base. Vestiture of

ground cover of rather stout, almost hairlike setae, each two-thirds as long as erect setae and slightly shorter on declivity; erect setae in central rows on each interstriae equal in length to two-thirds distance between rows.

Distribution: Brazil: Corumba, Mato Grosso.

Notes: The above treatment was based on the female holotype from Brazil.

Chramesus simplicis Wood

Plate XXIII

Chramesus simplicis Wood, 1971:3. Holotype ♂; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:269)

Diagnosis: Body rather slender; striae punctures obscure to obsolete; elytral setae hairlike; lateral margin of male frons a simple crest, unmarked by special tubercles or beading.

Male: Length 2.0–2.5 mm, 2.1 times as long as wide; color almost black. Frons deeply, broadly concave from epistoma to upper level of eyes, surface reticulate, punctures sparse, minute; epistomal margin not sharply defined; lateral margin subacute on lower third, middle third with long, hairlike setae; antennal club 1.7 times as long as wide. Pronotum 0.84 times as long as wide; surface reticulate, dull; punctures replaced by small to medium-sized, rounded tubercles; vestiture of fine, moderately long, rather abundant hair. Scutellum rather large for this genus. Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; striae not impressed, punctures very small, shallow (obscurely impressed in some specimens); interstriae almost flat, five times as wide as striae, subshining. Declivity restricted to posterior one-third, convex, steep; sculpture as on disc. Vestiture hairlike, central interstitial rows obscurely indicated only on declivity; setae varying from moderately long to long, rather abundant.

Female: Similar to male except frons weakly convex, almost flat on lower half, lateral margins not clearly marked; pronotal asperities slightly larger.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km W Merida, Merida, 12-I-1970, 2500 m, native bamboo, SLW.

Biology: Parental tunnels occurred at nodes. Larvae were not present.

Notes: The above treatment was based on the type series of 35 specimens.

Chramesus acacicolens Wood

Chramesus acacicolens Wood, 1969:3. Holotype ♂; Finca La Pacifica, 4 km NW Canas, Guanacaste Prov., Costa Rica; USNM, Washington (References in Wood & Bright c1992:263)

Diagnosis: Distinguished from *denticulatus* Wood by the larger size; by the presence of a small denticle on the lateral margin of the frons in most males; and by the erect interstitial scales being three times as long as the ground setae.

Male: Length 1.5–1.8 mm, 1.6 times as long as wide; color brown. Frons broadly, moderately concave from epistoma to upper level of eyes, surface strongly reticulate, punctures minute, mostly obsolete; epistomal margin smooth, shining, feebly elevated; lateral margins on lower half acutely elevated, a minute denticle often present on crest at antennal insertion; glabrous except sparse, short setae at margins, eyes of normal size. Pronotum 0.75 times as long as wide; widest at base, sides strongly arcuate and converging on basal two-thirds then weakly constricted before rather narrowly rounded anterior margin; surface obscurely reticulate, rather dull; a few punctures on disc near base, anterior areas with moderately numerous, small to minute, rounded tubercles; vestiture of moderately slender scales each about 6 times as long as wide. Elytra 1.03 times as long as wide, 1.5 times as long as pronotum; 2 or 3 obscure submarginal crenulations behind marginal row; striae abruptly, rather shallowly impressed, punctures close, rather coarse; interstriae about twice as wide as striae, surface smooth, shining, with numerous minute punctures, central row of each interstriae armed by a row of small, usually pointed tubercles. Declivity broadly convex, very steep; sculpture almost as on disc except striae and interstriae narrower, interstitial tubercles smaller, some often obsolete. Vestiture of abundant, short interstitial ground scales, each scale slightly longer than wide and each with a central row of erect scales, each erect scale three times as long as ground setae and six times as long as wide, and equal in length to slightly more than half distance between rows.

Female: Similar to male except frons convex, lateral margins not elevated.

Distribution: Costa Rica to Venezuela.

Venezuela: 40 km E Canton, Barinas, 8-III-1970, 70 m, No. 872, Mimosaceae sp., SLW.

Biology: Removed from phloem tunnels in broken twigs less than 2 cm in diameter.

Notes: The above treatment was based on the type series of 82 specimens from Costa Rica and on 21 specimens from Venezuela.

Chramesus neglectus Schedl

Chramesus neglectus Schedl, 1978:296. Holotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:267)

Diagnosis: Distinguished from *denticulatus* Wood by the larger size; by the stouter body; by the greatly enlarged eyes; by the discal striae not being impressed; and by other characters described below. This species is not closely related to others in this species group.

Male: Length 1.4–1.5 mm, 2.1 times as long as wide; color yellowish brown. Frons broadly, shallowly concave from epistoma to slightly below upper level of eyes, epistomal margins shining, weakly elevated, surface subreticulate to obscurely granulate, punctures minute, obscure, vestiture of moderately long, rather

abundant hair; eyes very coarsely faceted, greatly enlarged, separated both above and below by half width of an eye. Pronotum 0.75 times as long as wide; surface strongly reticulate, punctures moderately abundant, small, rather obscure, a few replaced by minute, rounded granules; vestiture moderately numerous, rather short, half of slender recumbent hair, half of stout, almost scalelike setae. Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; bases with about five minute submarginal crenulations; disc occupying basal two-thirds of elytral length; striae not impressed, punctures rather small, moderately impressed; interstriae twice as wide as striae, smooth, shining, punctures sparse, minute, each with a central row of very small, rounded tubercles. Declivity strongly convex, steep; declivital interstriae as wide as striae, sculpture about as on disc. Vestiture of minute strial hair, of sparse, slender ground setae on posterior half, and of a central row of erect, slender scales on each interstriae (each ground scale two-thirds as long as erect setae), each erect seta on declivity about six times as long as wide, more slender on anterior half.

Female: Similar to male except frons convex, reticulate; eyes separated above by width of an eye, facets smaller; asperities on lateral areas of pronotum much larger, more numerous.

Distribution: Brazil: Nova Teutonia [Santa Catarina], IX-1972, 300–500 m, F. Plaumann.

Notes: The above treatment was based on a male “type” (1.5 mm) and a female “type” (1.8 mm) in the Schedl Collection; however, in the original description a “holotypus (das grossere Exemplar)” and a “paratypus” are designated. The larger female, therefore, is here recognized as the holotype and the male is designated as the allotype of *neglectus* Schedl.

Chramesus denticulatus Wood

Chramesus denticulatus Wood, 1971:6. Holotype ♂; 20 km SW El Vigia, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:265)

Diagnosis: Lateral margin of male frons subacute, unarmed by a tubercle or special sculpture; male epistomal margin acutely elevated on at least median one-fourth.

Male: Length 1.3–1.4 mm, 1.6 times as long as wide; color yellowish brown, setae pale. Frons broadly concave on a subcircular pattern from epistoma to upper level of eyes, surface reticulate, with a few fine granules near upper margins; lateral margins subacutely elevated on lower third, unarmed by special sculpture; vestiture sparse, short, longer on lateral margins; epistomal margin acutely elevated on at least median one-fourth. Pronotum 0.80 times as long as wide; surface reticulate, tubercles small, mostly rounded. Scutellum very small. Elytra 1.16 times as long as wide, 1.5 times as long as pronotum; striae slightly impressed, punctures distinct;

interstriae twice as wide as striae, almost shining, with abundant, minute, confused punctures and a central row of tubercles, tubercles near and on declivity distinctly larger. Declivity on posterior half, convex, steep; striae deeper and interstriae narrower than on disc. Vestiture of ground cover of short, rather abundant, slender (not hairlike) setae and central rows of erect scales, each scale about three times as long as wide, about one-third as long as distance between rows, about half as long as distance between scales within a row.

Female: Similar to male except frons convex, epistomal elevation less strongly developed; tubercles on pronotum slightly larger.

Distribution: Costa Rica to Venezuela: 20 km SW El Vigia, Merida, 21-XI-1969, 50 m, *Bauhinia* liana, SLW.

Biology: The specimens were just entering a cut stem 2 cm in diameter. The galleries were not fully developed.

Notes: The above treatment was based on the holotype, allotype, and 1 male paratype and 2 female paratypes.

Chramesus minor Eggers

Chramesus minor Eggers, 1951:144. Lectotype ♂; Corumba, Mato Grosso, Brazil; USNM, Washington, designated by Anderson & Anderson 1971:20 (References in Wood & Bright c1992:267)

Diagnosis: Distinguished from *denticulatus* Wood by the less extensive impression on the male frons, with the epistoma not elevated; by the smooth, shining pronotum; and by the strongly flattened ground scales on pronotum and elytra.

Male: Length 1.3 mm, 2.0 times as long as wide; color yellowish brown, scales pale. Frons moderately concave from epistoma to upper level of eyes, impression not reaching margin of eyes; epistomal margin subacute, not elevated; surface smooth, shining below, subreticulate above, punctures small, shallow, not close, vestiture sparse, rather short, coarse. Pronotum 0.80 times as long as wide; anterior half armed by small asperities, including about 8 on anterior margin; surface smooth, shining, punctures small, shallow, rather abundant; vestiture of small, abundant scales, each about as wide as long. Elytra 1.4 times as long as wide, 1.9 times as long as pronotum; bases of interstriae 1–4 armed by a total of four submarginal crenulations; striae not impressed, punctures moderately coarse, deep; interstriae about one and one-half times as wide as striae, smooth, shining, punctures small, numerous, each with a row of small tubercles bearing erect setae. Declivity convex, steep; striae and interstriae slightly narrower than on disc. Vestiture of abundant, short scales, each as wide as long, and erect bristles almost twice as long as scales, each about 6–8 times as long as wide.

Distribution: Brazil: Corumba in Mato Grosso.

Notes: The above treatment was based on the male lectotype.

Chramesus asperulus Schedl

Chramesus asperulus Schedl, 1978:294. Holotype ♀; Encruzilhada, Bahia, Brazil, 980 m; NHMW, Wien (References in Wood & Bright c1992:263–264)

Diagnosis: Distinguished from *minulus* Wood by the smaller size; by the larger interstitial ground scales, the erect setae much longer than the ground setae; and by the longer, more slender setae on the anterior margin of the pronotum.

Male: Not seen. The male “type” of Schedl is actually a female.

Female: Length 1.4–1.6 mm, 1.9 times as long as wide; color brown. Frons essentially convex, with central half almost smooth, subreticulate; vestiture short, stout, rather numerous. Pronotum 0.70 times as long as wide; widest at base, sides weakly arcuate and converging on basal two-thirds to broadly rounded anterior margin; surface shining, punctures small, shallow, moderately abundant, almost a third of them replaced by small, rounded tubercles; vestiture of small, rather numerous scales uniformly distributed, each scale about 3–6 times as long as wide. Elytra 1.3 times as long as wide, 1.9 times as long as pronotum; about 7 submarginal crenulations behind marginal row; disc occupying slightly more than basal half; striae weakly impressed, punctures small, distinct; interstriae twice as wide as striae, surface shining, with numerous setiferous, minute punctures, each with a central row of pointed tubercles regularly spaced, each interstriae with a central row of erect scales, each scale twice as long as ground setae, about four times as long as wide, length of erect setae equal to almost half distance between rows.

Distribution: Brazil: Encruzilhada, Bahia, XI-1972, 980 m, M. Alvarenga (female type); M. Gerais, Pedra Azul, XI-1972, 700 m, Seabra & Olivera (“male type”).

Notes: The above treatment was based on the female holotype (labeled female type) and a female paratype that had been incorrectly labeled by Schedl as the “male type.”

Chramesus pumilus (Chapuis)

Chramesus pumilus (Chapuis), 1869:47 (*Rhopalopleurus*). Holotype ♂; Teapa, Tabasco, Mexico; IRSNB, Brussels (Synonymy and references in Wood & Bright c1992:268)

Chramesus tumidulus Blandford, 1897:170. Lectotype ♀; Las Mercedes, Guatemala; BMNH, London, designated by Wood 1972:143 (Synonymy and references in Wood & Bright c1992:268)

Chramesus panamensis Blackman, 1943:391. Holotype ♀; Canal Zone, Panama; USNM, Washington

Chramesus mexicanus Schedl, 1948:264. Holotype ♀; Comitán, Chiapas, Mexico; NHMW, Wien

Diagnosis: Distinguished by the presence of 2 pair of tubercles on lateral margin of male frons at level of antennal insertion; and by the hosts.

Male: Length 1.4–2.0 mm, 1.7 times as long as wide; color dark brown to almost black, vestiture pale. Frons broadly, moderately concave from epistoma to slightly

below upper level of eyes; surface reticulate, rather sparse, minute shining specks indicate obsolete punctures; vestiture sparse, fine, inconspicuous; lateral margins subacutely elevated on lower half, armed on crest by 2 pair of small tubercles (not clearly formed in some specimens); antennal club 2.1 times as long as wide. Pronotum 0.72 times as long as wide; surface reticulate, dull, rather coarsely asperate over most of surface, a few simple punctures concentrated on posteromedian area of disc, and a few scattered between asperities elsewhere; vestiture of stout almost scalelike pale bristles. Scutellum very small. Elytra 1.02 times as long as wide, 1.5 times as long as pronotum; striae distinctly impressed, punctures rather small, distinct; interstriae slightly more than twice as wide as striae, smooth, shining, with minute, confused, setiferous punctures, each interstriae with a central row of rather coarse tubercles from base to apex. Declivity commencing near middle of elytra, convex, steep; sculpture similar to disc except interstriae narrower, tubercles smaller. Vestiture of ground cover of small scales, each scale 1–2 times as long as wide, and central row of erect bristles (each bristle about 8 times as long as wide), each about half as long as distance between rows, spaced within a row by about 1.5 times length of a bristle.

Female: Similar to male except frons concave above, flattened on lower two-thirds, lateral margins rounded, lateral asperities on pronotum larger.

Distribution: Mexico (Jalisco) to Panama (Canal Zone), probably in South America (at least Colombia).

Hosts: *Canavalia*, *Phaseolus*, and “wild beans.”

Biology: Parent adults bore a diagonal tunnel in the main stem of wild, climbing beans, larvae then bore up and down the stem.

Notes: The above treatment was based on several hundred specimens from Mexico and Central America (south to the Canal Zone) some of which I compared directly to the holotype. Specimens have not yet been reported from South America, although several species of *Canavalia* occur there.

Chramesus aberrans Schedl

Plate XX

Chramesus aberrans Schedl, 1951:90. Lectotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:263)

Diagnosis: A small species allied to *aspericollis* Schedl but distinguished by the more shining, less reticulate pronotum; by the more slender elytral setae; and by the much more shallowly impressed male frons.

Male: Length 1.3–1.4 mm, 1.7 times as long as wide; color very dark brown, vestiture pale. Frons shallowly concave on median half of area above level of antennal insertions and ending distinctly below upper level of eyes, this area obscurely reticulate; lower half almost flat, weakly rugose-reticulate; lateral margins weakly elevated, a minute, obscure tubercle at level of antennal

insertion; vestiture of sparse, short, fine hair. Pronotum 0.70 times as long as wide; widest at base, sides strongly, arcuately converging toward broadly rounded anterior margin; surface weakly reticulate, basal fourth on median fourth rather finely, closely punctured, punctures replaced elsewhere by numerous low tubercles or small subasperate crenulations; vestiture short, moderately abundant, of 2 kinds, part small, slender, fine hair, most of stout, semirecumbent bristles. Elytra 0.95 times as long as wide, 1.4 times as long as pronotum; basal area with about 5 submarginal crenulations behind basal row; striae abruptly, weakly impressed, punctures large, deep, interstriae slightly wider than striae, weakly convex, almost smooth, punctures minute, each with a central, uniseriate row of rather closely spaced, subacute tubercles. Declivity broadly convex, steep; striae and interstriae narrower than on disc, striae punctures half as large; interstitial tubercles much smaller than on disc. Vestiture of rather abundant ground setae, each rather slender and half as long as erect setae; erect setae rather stout, half as long as distance between rows.

Female: Similar to male except frons convex, with a large central fovea, sculpture subrugose; fine, short setae mostly on lower half of frons.

Distribution: Brazil: Ilheus, Cepec, Bahia, II-III-1981, blacklight, Kaston; Nova Teutonia, Santa Catarina, VIII-1941, F. Plaumann.

Biology: Attracted to ultraviolet light.

Notes: The above treatment was based on a large, syntypic series. Schedl (1979:8) subsequently cited a holotype and an allotype for this species that are invalid under the Code of Nomenclature. That male is here designated as the lectotype of *Chramesus aberrans* Schedl and the female as the lectoallotype. Nine other specimens from Brazil were also examined. The illustration published by Schedl (1951:90) is not an accurate rendition of this species.

Chramesus ovalis Schedl

Chramesus ovalis Schedl, 1952:454. Lectotype ♀; Loreto, Misiones, Argentina; NHMW, Wien, present designation (References in Wood & Bright c1992:267)

Diagnosis: Distinguished from *aspericollis* Schedl by having the concavity of the male frons extending distinctly above the upper level of the eyes; by the minute to obsolete striae punctures; by the discal interstriae being about five times as wide as the striae; and by the slightly stouter erect interstitial setae.

Male: Length 1.8 mm, body 1.7 times as long as wide; color very dark brown, vestiture pale. Frons as in *aspericollis* except concave area extending slightly above upper level of eyes. Pronotum essentially as in *aspericollis*. Elytra very similar to *aspericollis* except striae weakly impressed, smooth, shining, striae punctures minute to obsolete, about one-fourth as wide as striae groove; interstriae three to five or more times as wide as striae, interstitial ground scales very slightly

longer than wide, erect setae very slightly shorter than in *aspericollis*.

Female: Similar to male except frons very broadly convex and lateral margins not elevated, a weak transverse impression distinctly above level of antennal insertions, almost flat and rugose-reticulate above impression to upper level of eyes (more narrowly convex and much less rugose-reticulate in *aspericollis* female); more strongly asperate in lateral areas of pronotum; striae punctures on disc and declivity rather large, impressed, interstriae about twice as wide as striae (similar to *aspericollis*).

Distribution: Argentina to Brazil.

Argentina: Loreto, Misiones, A.A. Ogloblin.

Brazil: Nova Teutonia, Santa Catarina, 1952, F. Plaumann.

Notes: The above treatment was based on the female "holotype" and the male "allotype" of Schedl and on another male and female from Brazil that were identified by Schedl. Type locality data and type designations were not given in the original description of this species. A female "holotype" and male "allotype" were designated for this species by Schedl (1979:181). However, Schedl overlooked the fact that under the International Code on Zoological Nomenclature, a holotype can be designated only in the original publication of a newly established species. For that reason, his "holotype" and "allotype" designations are invalid. I here designate Schedl's male "allotype" as the lectotype of this species and his female "holotype" as the allotype for *Chramesus ovalis* Schedl. This reversal was made because the male, not the female, has the characters that most clearly distinguish this species (see above).

Chramesus aspericollis Schedl

Plate XXI

Chramesus aspericollis Schedl, 1938:23. Lectotype ♂; Isla Martin Garcia, Buenos Aires, Argentina; NHMW, Wien, present designation (References in Wood & Bright c1992:263)

Diagnosis: Male frons armed by a low, subquadrate elevation at level of antennal insertion; striae punctures minute; interstitial ground setae of small scales, each scale slightly longer than wide. Very similar to *ovalis* Schedl.

Male: Length 1.5–1.8 mm, 1.7 times as long as wide; color very dark brown, vestiture pale. Frons impressed from epistoma to slightly below upper level of eyes, upper one-third flattened, lower two-thirds rather strongly concave, surface reticulate; lateral margin on most of lower one-third acutely elevated, crest forming a low, subquadrate elevation at or just below level of antennal insertion; vestiture sparse, short, inconspicuous; antennal club 2.1 times as long as wide. Pronotum 0.80 as long as wide; surface reticulate, asperities rather small, except punctured at base on median one-fourth; vestiture of short, stout bristles. Scutellum very small, subcircular. Elytra 1.1 times as long as wide, 1.5 times

as long as pronotum; striae very slightly impressed, smooth, shining, punctures small; interstriae slightly more than twice as wide as striae, shining, with minute, confused, setiferous punctures, bristle-bearing punctures not granulate. Declivity confined to posterior half of elytra length, steep, broadly convex; striae and interstriae slightly narrower than on disc. Vestiture of ground cover of abundant scales, each scale slightly longer than wide, and erect bristles, each bristle at least twice as long as ground cover, stout, equal in length to less than half distance between rows, spaced within a row by 1.5 times length of a bristle.

Female: Similar to male except frons broadly convex, margins rounded; pronotal asperities distinctly larger; each bristle-bearing puncture on interstriae replaced by a small tubercle.

Distribution: Argentina to S Brazil.

Argentina: Loreto, Misiones, A.A. Ogloblin; Buenos Aires, Isla San Martin Garcia (male and female syntypes).

Brazil: Nova Teutonia, Santa Catarina, XI-1956, 300–500 m, F. Plaumann (Schedl series).

Hosts: *Celtis spinosa*, *Nectandra* sp. (Bright & Skidmore 2002:39).

Notes: The above treatment was based on Schedl's male syntype and his female syntype, on a male and a female from Nova Teutonia from Schedl's series, and on 2 male and 1 female paratypes from Argentina and on 10 specimens from Brazil. The male "type" (a syntype) is here designated as the lectotype of *Chramesus aspericollis* Schedl and the female "type" as the lectoallotype of this species.

Chramesus setiger Schedl

Chramesus setiger Schedl, 1951:92. Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:269)

Diagnosis: Distinguished from *aspericollis* Schedl by the weakly reticulate pronotum disc; by the discal striae not being impressed, with most punctures on middle half of disc obsolete; and by the more slender ground setae on the discal interstriae.

Male: Length 1.8–1.9 mm, 1.5 times as long as wide; color very dark brown, almost black, vestiture pale. Frons broadly, rather deeply concave from epistoma to slightly below upper level of eyes; surface largely shining, punctures minute, almost obsolete; vestiture sparse, rather long; lateral margin rather weakly subacute half distance to upper level of eyes, below level of antennal insertions margin elevated into a small denticle; vertex rather coarsely, shallowly punctured, scape ornamented by a small tuft of hair. Pronotum 0.70 times as long as wide; widest at base, convergently arcuate to broadly rounded anterior margin; surface moderately reticulate on anterior half, weakly reticulate behind, median third on basal half rather coarsely, deeply, closely punctured; vestiture moderately abundant, very fine hair and rather coarse bristles intermixed; several small asper-

ities in lateral areas. Elytra 1.02 times as long as wide, 1.4 times as long as pronotum; basal areas armed by about 6 submarginal crenulations behind basal row; striae not impressed, punctures on 1 small, regular, 2 and 3 with a few punctures at base then obsolete to near base of declivity; interstriae about five times as wide as striae, smooth, shining, punctures minute, rather numerous. Declivity occupying posterior half of elytra length; very broadly convex, steep; striae weakly impressed, punctures very small, impressed; interstriae three to four times as wide as striae, almost smooth, shining, with no indication of tubercles or granules, punctures minute. Vestiture in ground cover of short, abundant, slender setae each 4–6 times as long as wide on disc, 3–4 times on declivity, and central rows of erect, rather stout bristles, each bristle 2–3 times as long as ground setae.

Female: Similar to male except frons broadly convex, lateral margins not elevated or armed, reticulate, upper half irregularly, obscurely punctured, vestiture of fine, short hair; asperities in lateral areas of pronotum much larger; interstriae on disc and declivity each with a central row of subacutely pointed tubercles, larger on disc, smaller on declivity, obsolete before apex.

Distribution: Brazil: Nova Teutonia [Santa Catarina], 1946, F. Plaumann.

Notes: The above treatment was based on the male and female syntypes in the Schedl Collection. Schedl (1979:226) incorrectly designated these specimens as the female holotype and male allotype. Because a holotype designation can be made only in the original publication that validates a new name, I here designate his "holotype" as the female lectotype and the male as the lectoallotype of *Chramesus setiger* Schedl.

Chramesus priscus Wood

Chramesus priscus Wood, 1971:7. Holotype ♂; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:268)

Diagnosis: Male epistomal margin armed by a transverse carina; male lateral elevation on frons at and above level of antennal insertion with crest rounded and reticulate; interstitial ground setae on disc absent.

Male: Length 2.2–2.4 mm, 1.9 times as long as wide; color brown, vestiture pale. Frons broadly, rather deeply concave from epistoma to upper level of eyes, surface reticulate, upper half with sparse, minute granules; epistomal margin on median half armed by an acute transverse carina; lateral margin from level of antennal insertion one-third distance toward upper level of eyes rather broadly elevated, summit of elevation rounded and reticulate; vestiture of very fine, long, sparse hair; antennal club 3.0 times as long as wide, apex pointed. Pronotum 0.71 times as long as wide; surface strongly, uniformly reticulate, tubercles small, isolated, rather sparse; vestiture slender, rather short, moderately abundant. Elytra 1.3 times as long as wide, 2.1 times as long as pronotum; striae very weakly impressed, punctures

moderately large, impressed; interstriae twice as wide as striae, almost smooth, shining, each with a central row of very small bristle-bearing granules. Declivity confined to slightly more than posterior one-fourth, convex, steep; striae more strongly impressed, interstriae narrower than on disc. Vestiture mostly of erect bristles on disc, each bristle slender, less than half as long as distance between rows; on declivity and on discal interstriae 1–3 with confused supplemental setae similar to erect bristles.

Female: Similar to male except frons convex, lateral margins not elevated, a slight transverse impression below level of antennal insertion, epistomal carina weak, pronotal asperities rather coarse laterally.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 9-XII-1969, 2500 m, No. 175, *Phoradendron*, SLW.

Biology: Boring below phloem in small stems of mistletoe.

Notes: The above treatment was based on the holotype, allotype, and 9 paratypes in the type series.

Chramesus orinocensis Wood

Chramesus orinocensis Wood, 1971:4. Holotype ♂; Campamento Rio Grande, 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:267)

Diagnosis: Distinguished from *vinealis* Wood by the regularly impressed strial punctures; by the much finer setae on the male frons; and by the smaller, less numerous pronotal asperities.

Male: Length 1.6–1.9 mm, 1.5 times as long as wide; color dark brown to almost black, vestiture pale. Frons broadly, moderately concave from epistoma to above upper level of eyes; surface strongly reticulate (almost rugose-reticulate) on upper half, dull, almost smooth below; lateral margin acutely, rather strongly elevated from level of antennal insertion one-third distance toward upper level of eyes; vestiture fine, sparse, inconspicuous; antennal club 2.1 times as long as wide. Pronotum 0.80 times as long as wide; surface reticulate, rather dull, most of disc with fine, obscure punctures, anterior and lateral areas with rather sparse tubercles or fine asperities; vestiture short, of a mixture of slender and almost scalelike setae, scales about 4 times as long as wide. Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; striae slightly impressed, punctures distinctly impressed, moderately coarse; interstriae slightly more than twice as wide as striae, almost smooth, punctures for ground setae small, confused, bristle-bearing punctures not granulate. Declivity occupying posterior half, convex, steep; striae deeper and striae and interstriae narrower than on disc. Vestiture in ground cover of short, confused scales, each scale slightly longer than wide, and central rows of erect bristles, each bristle about 6 times as long as wide, slightly less than half as long as distance between rows, spaced within a row by slightly more than length of a bristle.

Female: Similar to male except frons convex, lateral margins not marked by an elevation; pronotal asperities slightly larger; some females with a few small tubercles at bases of interstitial bristles.

Distribution: Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 568, “Bejuco trinitaria” (det. Balbino Rodriguez), SLW.

Notes: The above treatment was based on the holotype, allotype, and 71 paratypes.

Chramesus vinealis Wood

Chramesus vinealis Wood, 1971:7. Holotype ♂; 30 km N Canon Zancudo, Zulia, Venezuela; USNM, Washington (References in Wood & Bright c1992:270)

Diagnosis: Distinguished from *orinocensis* Wood by the larger size; by the less extensively impressed male frons; by the coarser setae on the male frons; by the minute, more widely spaced strial punctures; and by the larger, more numerous pronotal asperities.

Male: Length 1.9–2.1 mm, 1.5 times as long as wide; color dark brown to almost black. Frons about as in *orinocensis* except concavity ending distinctly below upper level of eyes, setae shorter, less abundant. Elytral striae on disc narrower, punctures much smaller, often minute.

Female: Similar to female *orinocensis* except pronotal asperities larger; interstriae with a central row of moderately large tubercles at bases of erect, bristle-bearing setae.

Distribution: Venezuela: 30 km N Canon Zancudo, 4-VI-1970, 10 m, No. 520, liana, SLW.

Notes: The above treatment was based on the holotype, allotype, and 129 paratypes.

Chramesus impolitus Wood

Plate XXII

Chramesus impolitus Wood, 1971:6. Holotype ♂; Campamento Rio Grande, 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:266)

Diagnosis: This species and *imporcatus* Wood are unique in the genus in having the lateral elevation on the male frons divided into a lower, subquadrate element at level of antennal insertion and an upper element on upper third just below upper level of eye; this species differs from *imporcatus* in having lower lateral element on male frons less strongly elevated, more broadly rounded at its summit, and interstitial setae on disc without a ground cover.

Male: Length 1.8–2.1 mm, 1.6 times as long as wide; color dark brown to almost black. Frons broadly, deeply concave from epistoma to distinctly above upper level of eyes; surface strongly reticulate; lateral margin below level of antennal insertion strongly, thickly elevated, its summit rounded; lateral margin on upper third (to just below upper level of eyes) strongly, acutely elevated; vestiture short, fine, inconspicuous; antennal club 2.2

times as long as wide. Pronotum 0.83 times as long as wide; a few obscure punctures near posterior margin on median half, remaining area with moderately abundant, isolated, small asperities; vestiture of short, coarse, rather sparse setae. Elytra 1.0 times as long as wide, 1.2 times as long as pronotum; striae feebly impressed, punctures moderately small, impressed; interstriae slightly more than twice as wide as striae, smooth, slightly shagreened, each bearing a row (two rows on 2 on disc) of rather coarse, rounded tubercles. Declivity occupying slightly more than posterior half, convex, steep; striae and interstriae narrower than on disc, tubercles abruptly much smaller, pointed to apex. Vestiture of stout, suberect bristles, in uniseriate rows from base to apex, except confused on 2.

Female: Similar to male except frons convex, its lateral margins not marked; interstitial tubercles subacutely pointed.

Distribution: Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 567, *Brownia*, SLW.

Biology: Breeding in small stems of a broken shrub. The broken or recently cut host had a very strong odor that somewhat resembled fresh, very potent pig excrement.

Notes: The above treatment was based on the holotype, allotype, and 54 paratypes.

Chramesus imporcatus Wood

Chramesus imporcatus Wood, 1971:5. Holotype ♂; 7 km NW Socopo, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:266)

Diagnosis: Distinguished from *impolitus* Wood by the more strongly, acutely elevated lateral crest on male frons; and by the presence of interstitial ground vestiture on the disc.

Male: Length 1.8–2.3 mm, 1.6 times as long as wide; color dark brown to almost black. Frons about as in *impolitus* except lateral elevation below level of antennal insertion more narrowly, acutely elevated, its summit shining. Pronotum about as in *impolitus*. Elytra resembling *impolitus* except striae punctures smaller, deeper, interstitial punctures smaller, about two-thirds as large, interstitial ground vestiture present, rather abundant.

Female: Similar to male except frons convex, its lateral margins not marked.

Distribution: Venezuela: 7 km NW Socopo, Barinas, 13-II-1970, 200 m, No. 323, Palito de Cruz, SLW; El Vigia, Merida, 22-X-1969, 100 m, unidentified seedling, SLW; Canon Zancudo, Zulia, 10 m, unidentified tree branch, SLW.

Hosts: Palito de Cruz.

Biology: Breeds in phloem tissues of host.

Notes: The above treatment was based on the holotype, allotype, 9 paratypes, and 22 other specimens from Venezuela.

Chramesus striatus Eggers

Chramesus striatus Eggers, 1943:344. Holotype ♀; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:269).

Diagnosis: Not in the above key. Named from a female of unknown phylogenetic position, although superficial features suggest it should be placed near *imporcatus* Wood or *phloeotriboides* Schedl. It is distinguished by the comparatively large size; by the presence of small pronotal asperities on the lateral fourths only; by the strongly reticulate pronotum, with small, shallow punctures; by the smooth, dull elytral surface, with rows of interstitial tubercles, with a ground cover of small, interstitial scales on the posterior disc and declivity and rows of slender, erect setae.

Female: Length 2.3 mm, 1.8 times as long as wide; color very dark brown. Frons broadly convex, surface reticulate, sparsely pubescent; on lateral margin at level of antennal insertion, a very weak, obscurely elevated row of granules extending dorsad for about 4 granules (indicating general phylogenetic position of this species). Pronotum 0.81 times as long as wide; surface dull, strongly reticulate; less than lateral fourths with small, rather numerous asperities; recumbent vestiture fine, short, moderately abundant. Elytra 1.2 times as long as wide, 1.8 times as long as pronotum; bases of interstriae 2–4 armed by a total of eight submarginal crenulations; striae distinctly impressed, punctures rather strongly impressed, moderately large except smaller on basal one-fourth; interstriae distinctly wider than striae, surface smooth, dull, each with a uniseriate row (slightly confused on 3) of narrow, rather high tubercles, minute punctures on 1 and 2 to base and posterior half of 3. Declivity broadly convex, steep; striae narrower and more strongly impressed than on disc, interstriae narrower, tubercles smaller. Vestiture of ground cover of short scales (each two or three times as long as wide) on declivity and to base on 1 and 2 and to middle of disc on 3, and erect coarse hairlike setae in uniseriate interstitial rows, each erect seta two-thirds as long as distance between rows.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the female holotype. In order to find its proper position in phylogeny a male is needed.

Chramesus granulipennis Schedl

Chramesus granulipennis Schedl, 1959:547. Holotype ♂; Rondon, Parana, Brazil; NHMW, Wien (References in Wood & Bright c1992:266)

Diagnosis: Distinguished from all known members of this genus by the unique sculpturing of the male frons; and by the large, rounded interstitial spines on the elytral disc.

Male: Length 2.1 mm, 1.6 times as long as wide; color almost black. Frons deeply, broadly concave from

epistoma to vertex; surface of concave area rugose-reticulate on more than upper half, smooth, shining below level of antennal insertions; vestiture almost obsolete, of a few minute, hairlike setae; lateral margins with an acutely elevated costa (its crest marked by 16 beads) from upper level of eyes two-thirds of distance to level of antennal insertions, a coarse, obtuse denticle on margin below level of antennal insertions, crest between denticle and beaded area rather broadly rounded, weakly elevated; antennal club 2.0 times as long as wide. Pronotum 0.80 times as long as wide; widest at base, rather strongly, arcuately converging to narrowly rounded anterior margin; surface strongly reticulate, closely armed by rather high, narrow, rounded tubercles uniformly distributed; vestiture of rather short, stout, recumbent setae of moderate abundance. Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; disc occupying basal half of elytra length; basal area with about 16 submarginal crenulations behind basal row; striae slightly impressed, punctures rather large, deep; interstriae slightly wider than striae (except 2 twice as wide), 1 and 3–5 armed by uniseriate rows of large, somewhat rounded, closely set tubercles each as high as wide, 2 with a double row to base of declivity then uniseriate on declivity. Declivity broadly convex, steep; striae and interstriae narrower than on disc, tubercles not as close, slightly smaller, on 1–8. Ground vestiture entirely absent; erect interstitial setae in uniseriate rows, each rather stout, tapered on its apical half to a narrowly acute point, each equal in length to about half distance between rows.

Distribution: Brazil: Rondon [Parana], 24°38' S, 54°07' W, V-1962, F. Plaumann.

Notes: The above treatment was based on the male holotype from Brazil.

Chramesus peruanus Schedl

Chramesus peruanus Schedl, 1961:223. Holotype ♂; Urubamba, Ollantaitambo, Dep. Cruzeta, Peru; NHMW, Wien (References in Wood & Bright c1992:267)

Diagnosis: Distinguished from *phloeotriboides* Schedl and *advena* Schedl by the scalelike interstitial ground setae; by the abrupt, slightly projecting upper end of the lateral crest on the male frons; and by the larger size.

Male: Length 3.2 mm, 1.9 times as long as wide; color dark reddish brown. Frons broadly, deeply concave from epistoma to well above upper level of eyes, lateral margins subacutely elevated below level of antennal insertions and armed by about 2 small, weak denticles, crest above level of antennal insertions more strongly, more narrowly, almost subserrately elevated to its abrupt, subdentate termination above at a point half distance from antennal insertions to upper level of eye; concave area smooth below level of antennal insertions, upper area rather finely punctured, many punctures subtuberculate; vestiture in concave area hairlike, rather abun-

dant, moderately long; scape with a small tuft of hair; club 2.5 times as long as wide. Pronotum 0.74 times as long as wide, widest at base, basal two-thirds strongly, convergently arcuate toward broadly rounded anterior margin; surface smooth, shining, closely, rather finely punctured, a few punctures on lateral thirds very weakly tuberculate; vestiture of stout, semirecumbent, rather short setae. Elytra 1.1 times as long as wide, 1.6 times as long as pronotum; disc occupying basal one-fourth of elytral length; basal area with about 7 submarginal crenulations behind basal row; striae not impressed, punctures very small; interstriae about four times as wide as striae, punctures minute, without any tubercles. Declivity broadly convex, moderately steep above, very steep below; sculpture as on disc. Vestiture of abundant, confused, ground scales, each scale about 4–6 times as long as wide at base, becoming as long as wide on declivity; erect setae in central rows, each seta slender, about as long as ground setae at base, about twice as long as ground setae on declivity.

Distribution: Peru: Urubamba, Ollantaitambo, Dep. Cruzeta, 31-I-1949, G. Kuschel.

Notes: The above treatment was based on the male holotype from Peru.

Chramesus advena Schedl

Chramesus advena Schedl, 1951:91. Lectotype ♀; Cachoeirinha-Una, Bahia, Peru; NHMW, Wien, present designation (References in Wood & Bright c1992:263)

Diagnosis: Distinguished from *phloeotriboides* Schedl by the presence of ground setae on each margin of discal interstriae, each seta as slender as those in central row, each about four times as long as wide; and by the reticulate pronotum.

Male: Length 1.7–1.8 mm, 1.7 times as long as wide; color very dark brown, pronotum almost black. Frons deeply, broadly concave from epistoma to upper level of eyes, lateral margin acutely elevated on slightly less than lower half, obtusely margined above, crest of elevation uniform but its mesal margin marked by beading (5 beads); surface of concavity reticulate, punctures not clearly evident, setae of minute hair. Pronotum 0.74 times as long as wide; widest at base, sides convergently arcuate to rather narrowly rounded anterior margin; surface reticulate, punctures moderately large, impressed, irregularly spaced by diameter of a puncture, without any tubercles or asperities; vestiture of rather sparse, stout, semirecumbent, rather short setae. Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; basal area with about 3 submarginal crenulations behind basal row; disc occupying basal half of elytra length; striae not impressed, punctures rather large, strongly impressed; interstriae slightly wider than striae, smooth, shining, punctures very small, about a fourth as wide as those of striae, unmodified at base, gradually replaced by a small tubercle toward base of declivity. Declivity strongly convex, steep; striae and interstriae narrower

than on disc, sculpture similar. Vestiture of interstitial setae, ground setae at each margin on posterior half, erect setae in central row on each interstriae, only slightly longer than ground setae on disc, twice as long on declivity, both of rather stout bristles.

Female: Similar to male except frons broadly convex, lateral margins rounded (not elevated), surface almost rugose-reticulate; about 4–10 low crenulations on lateral areas of pronotum; ground setae on declivity almost scalelike.

Distribution: Brazil: Cachoeirinha-Una, Bahia (type); Encruizilhada, 980 m, Bahia, XI-1972, M. Alvarenga; Corcovado, Guanabara, IX-1969, Alvarenga & Seabra; Nova Teutonia, Santa Catarina, III-1945, F. Plaumann.

Notes: The above treatment was based on 1 female syntype and on 2 other females and 1 male specimen from Brazil. Because this species was originally based on a syntypic series of females, the female "holotype" designated by Schedl (1979:12) is not valid. To correct the problem, I here designate the female syntype that was labeled as the holotype as the lectotype of *Chramesus advena* Schedl.

Chramesus phloeotriboides Schedl

Chramesus phloeotriboides Schedl, 1958:41. Holotype ♂; Gran Chaco, Argentina; NHMW, Wien (References in Wood & Bright c1992:268)

Diagnosis: Male frons with lateral margin acutely elevated from level of antennal insertion half distance toward upper level of eyes, its crest irregular but neither dentate nor beaded; interstitial ground setae confined to declivity.

Male: Length 2.3 mm, 1.8 times as long as wide; color dark brown, vestiture pale. Frons broadly concave from epistoma to well above upper level of eyes; concave area weakly reticulate on lower half, minutely, obscurely punctured below; lateral margins acutely elevated from level of antennal insertion half distance to upper level of eyes, its crest irregular but not dentate or beaded; vestiture of fine, long, erect, inconspicuous hair; antennal club 2.7 times as long as wide. Pronotum 0.80 times as long as wide; surface almost shining, obscurely reticulate; basal one-third on median one-half with fine punctures, remaining area with small tubercles, some in lateral areas forming small asperities; vestiture of rather coarse, semirecumbent hair of moderate length. Elytra 1.2 times as long as wide, 1.7 times as long as pronotum; striae distinctly impressed, punctures rather small; interstriae slightly more than twice as wide as striae, weakly convex, smooth, shining, each with a central row of small, setiferous tubercles, almost uniseriate except confused on posterior half of 3. Declivity on slightly less than posterior half of elytra length, convex, steep; striae and interstriae slightly narrower than on disc, interstriae with many small, setiferous punctures. Vestiture without ground setae on disc, sparsely present on declivity (each

scale slightly longer than wide); erect bristles rather slender, pointed, each half as long as distance between rows, spaced within a row by less than length of a bristle, uniseriate except confused on 3.

Female: Similar to male except frons broadly convex (frons of type covered by glue, not visible).

Distribution: Argentina: 21 km W Tucuman, P. Tucuman, 18-X-1968, L. & C.W. O'Brien; Gran Chaco, L. Bade.

Notes: The above treatment was based on the female holotype and on 1 male that had been compared by me directly to the holotype. Both are from Argentina.

Chramesus luteus Wood, n. sp.

Chramesus luteus Wood: Holotype ♂; Colombia; USNM, Washington, designated below

Diagnosis: Distinguished from *strigilis* Wood by the smaller size; by the confused ground scales on declivital interstriae 4, erect bristles on lower half.

Male: Length 1.7 mm, 1.6 times as long as wide; color yellowish brown, vestiture pale. Frons broadly concave from epistoma to upper level of eyes, surface shining on lower half, reticulate above, obscure punctures indicated by shining specks; lateral margin subacutely elevated on middle third beginning very slightly above level of antennal insertions, crest rather strongly marked by 10 "beads"; vestiture of rather sparse, fine, long hair; antennal club 2.0 times as long as wide. Pronotum 0.73 times as long as wide; surface weakly reticulate; a few small punctures near base on median one-fourth; asperities small, mostly in lateral areas. Elytra 1.06 times as long as wide, 1.6 times as long as pronotum; striae rather strongly impressed, punctures small, moderately impressed; interstriae about as wide as striae, each with a central row of narrow, bristle-bearing, rather strongly, acutely elevated crenulations, each about one-third as wide as an interstriae, most spaced within a row by width of an interstriae. Declivity occupying very slightly more than posterior half of elytra length, convex, steep; striae and interstriae slightly narrower than on disc; interstitial tubercles much smaller than on disc. Vestiture of abundant scales in ground cover, each scale slightly longer than wide; erect bristles in uniseriate rows, each arising from posterior margin of a tubercle, each bristle stout, most about 6 times as long as wide, 2 or 3 times as long as ground setae, almost half as long as distance between rows, spaced within a row by 2 or 3 times length of a bristle; declivital interstriae 4 with ground scales confused and erect bristles present on lower half.

Distribution: Colombia.

Type material: The male holotype is labeled "Colombia." It is in the U.S. National Museum, Washington.

Chramesus granulatus (Eggers)

Chramesus granulatus (Eggers), 1928:94 (*Pagiocerus*). Holotype ♂; E Bolivia [Cochabamba on label of holotype]; NHMW, Wien (References in Wood & Bright c1992:265)

Diagnosis: Distinguished from *phloeotriboides* Schedl by the larger size; by the strongly reticulate pronotum, with numerous tubercles to base; and by the more strongly impressed discal striae and more coarsely sculptured interstriae.

Male: Length 2.8 mm, 1.8 times as long as wide; color almost black. Frons broadly, deeply concave from epistoma to above upper level of eyes; lateral margins acutely elevated below and more strongly above level of antennal insertions, its crest weakly subserrate, declining gradually to inner margin of eye; surface of concave area reticulate except shining on epistoma, very fine punctures sparse, vestiture minute, hairlike, sparse. Pronotum 0.80 times as long as wide; very broadly convex, surface strongly reticulate, dull, punctures replaced by small, rounded tubercles (smaller in anteromedian area); vestiture of rather short, stout, moderately abundant hair. Elytra 1.2 times as long as wide, 1.8 times as long as pronotum; basal area with about 20 submarginal crenulations; disc occupying more than basal half; striae narrowly, rather deeply impressed, punctures small; interstriae about twice as wide as striae, convex, surfaces shining, with almost uniseriate, rather coarse crenulations (transversely subacute). Declivity broadly convex, steep; striae and interstriae narrower than on disc, sculpture about as on disc. Vestiture in ground cover of numerous small scales (each twice as long as wide) on declivity, mostly absent on disc except for a few hairlike setae, erect setae almost hairlike, in indefinite rows on and near declivity, obscure on disc.

Distribution: Peru: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the male holotype.

Chramesus strigilis Wood

Chramesus strigilis Wood, 1971:4. Holotype ♂; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:269)

Diagnosis: Distinguished from *luteus* Wood by the larger size; by the presence of interstitial ground setae on disc; and by the presence of uniseriate ground setae on declivital interstriae 4 with no erect bristles present.

Male: Length 1.9–2.3 mm, 1.6 times as long as wide; color dark brown, setae rather dark. Frons broadly, strongly concave from epistoma to well above upper level of eyes; surface reticulate above, almost smooth below, vestiture sparse, fine, inconspicuous; lateral margins strongly, acutely elevated from immediately above level of antennal insertion two-thirds distance to upper level of eyes, its crest clearly marked by 10–13 beads (variable between specimens and between right and left sides of same specimen); antennal club 1.2 times as long as wide. Pronotum 0.76 times as long as wide; surface reticulate, median half from anterior margin to base with shallow punctures interspersed with small tubercles, tubercles larger, subasperate laterally; vestiture rather sparse, coarse, recumbent. Elytra 1.14 times as

long as wide, 1.7 times as long as pronotum; striae moderately impressed, punctures rather small, close; interstriae slightly wider than striae, weakly convex, with fine punctures bearing ground scales, central row of pointed tubercles bearing erect bristles. Declivity occupying slightly less than posterior half of elytra length; interstriae narrower than on disc, ground setae on lower half of 2 and 4 uniseriate. Vestiture of rather abundant ground scales, each about twice as long as wide and erect bristles, each bristle 2 (at base) to 3 times as long as ground scales, some 8 times as long as wide, about two-thirds as long as distance between rows, spaced within a row by one to four times length of a bristle (erect bristles absent on lower half of declivital interstriae 2 and 4).

Female: Similar to male except frons convex, its lateral margins not marked; pronotal asperities slightly larger.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 27-X-1969, 2500 m, No. 89, tree seedlings (trail cuttings), SLW.

Biology: In phloem of recently cut stems.

Notes: The above treatment was based on the holotype, allotype, and 33 paratypes.

Chramesus argentinae Wood, n. sp.

Chramesus argentinae Wood: Holotype ♂; Tafi del Valle, Tucuman, Argentina; USNM, Washington, designated below

Diagnosis: Interstitial ground setae on disc sparse, slender; erect interstitial bristles without tubercle at their base; lateral margin of male frons strongly elevated and beaded only on lower third of area above level of antennal insertion.

Male: Length 2.0 mm, 1.9 times as long as wide; color brown, vestiture pale. Frons broadly, deeply concave from epistoma to well above upper level of eyes; surface almost smooth and shining on lower half, reticulate and with small, isolated granules above; vestiture of fine, sparse, rather long hair; more numerous near upper margin; antennal club 2.6 times as long as wide. Pronotum 0.74 times as long as wide; surface smooth, shining; posterior one-third on median half finely punctured, remaining area with small, isolated tubercles, some tubercles in lateral areas finely subasperate; vestiture of moderately long, rather abundant, stout hair. Elytra 1.3 times as long as wide, 1.9 times as long as pronotum; striae weakly impressed, punctures small, deep, rather close; interstriae slightly more than twice as wide as striae, smooth, shining, without any tubercles, punctures very fine (a central row bearing erect bristles, a row on each margin next to striae [bearing ground setae]). Declivity confined to posterior half, convex, steep; striae narrower, more deeply impressed than on disc, interstriae weakly convex. Vestiture of sparse ground setae on margins of interstriae, each slender, about six to eight times as long as wide (stouter and more numerous on declivity), and erect, slender bristles, each bristle about two-thirds as long as distance between rows, spaced within a row by length of a bristle.

Female: Similar to male except frons shallowly, narrowly concave from epistoma to upper level of eyes, margins weakly marked; pronotum mostly, weakly reticulate, asperities distinctly larger; interstitial setae more slender.

Distribution: Argentina.

Type material: The male holotype and female allotype were taken at Tafi del Valle, Tucuman, Argentina, 23-XI-1947, R. Golbach, both mounted on one pin. The holotype and allotype are in the U.S. National Museum, Washington.

Chramesus globosus Hagedorn

Chramesus globosus Hagedorn, 1909:742. Holotype, sex?; Argentina, La Plata; Hamburg Museum, lost; based on series in USNM, Washington, det. Blackman before type was lost (References in Wood & Bright c1992:265)

Chramesus eurypterus Schedl, 1963:214. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:265). *New synonymy*

Diagnosis: Setae forming a variegated pattern of dark and pale scales; lateral margins of male frons acutely elevated, its crest beaded; basal half of pronotum closely, rather deeply punctured.

Male: Length 2.0–2.2 mm, 1.6 times as long as wide; color very dark brown, vestiture forming a variegated pattern of about 50 percent dark and 50 percent pale scales. Frons broadly, deeply concave from epistoma to upper level of eyes, surface shining below, reticulate above, vestiture of fine, long, moderately abundant hair; lateral margins acutely elevated just above upper level of antennal insertion half distance toward upper level of eyes, its crest clearly marked by 9 beads; antennal club 2.3 times as long as wide. Pronotum 0.80 times as long as wide; posterior one-half (central) or one-fourth (lateral) smooth, shining, closely, rather deeply punctured, rather coarsely asperate laterally, finely on anteromedian area; vestiture stout, rather short, almost scalelike, moderately abundant. Elytra 1.1 times as long as wide, 1.6 times as long as pronotum; striae distinctly impressed, punctures small; interstriae three times as wide as striae, surface smooth, shining, punctures very small, confused, rather numerous, without tubercles. Declivity confined to posterior half of elytra length, convex, steep; striae and interstriae narrower than on disc, sculpture similar. Vestiture of rather abundant ground scales, each slightly longer than wide and central rows of erect bristles; each bristle twice as long as ground scales, about six times as long as wide, each less than half as long as distance between rows, spaced within a row by one (base) to three (base of declivity) times length of a bristle; scales dark brown to pale, forming a variegated pattern.

Female: Similar to male except frons convex, margins not marked; pronotal asperities larger; erect interstitial bristles shorter.

Distribution: Argentina to Uruguay and Brazil.

Argentina: La Plata; Tucuman, 11 km W Las Cejar, 1-14-X-1967, L. Stange.

Brazil: Nova Teutonia, Santa Catarina, III-1954, II-1966, 300–500 m, F. Plaumann.

Uruguay: Montevideo, No. 1011-24, H.L. Parker, unidentified native wood.

Hosts: *Celtis spinosa* (Bright & Skidmore 2002:29), not seen by me.

Notes: The above treatment was based on 1 male from Argentina that Blackman compared to the holotype of *globosus* Hagedorn, on the male holotype and 1 female paratype of *eurypterus* from Brazil, and on 1 male and 1 female from Uruguay. The male holotype of *eurypterus* Schedl was compared directly by me to the specimens Blackman compared to the holotype of *globosus* before the type was lost at Hamburg.

Chramesus brasiliensis Nunberg

Chramesus brasiliensis Nunberg, 1962:224. Holotype ♂; Serra do Urucum, Corumba, Mato Grosso, Brasil; MZUSP, Sao Paulo (References in Wood & Bright c1992:264)

Diagnosis: Distinguished from *peniculus* Wood by the larger size; by the occurrence of subcrenulate tubercles on the anterior slope of the pronotum and larger, shallow punctures on the pronotum disc; by the much shorter more closely spaced erect interstitial setae, with erect setae present on declivital interstriae 2.

Male: Length 1.6 mm, 1.7 times as long as wide; color of pronotum brown, elytra rather pale brown. Frons rather deeply concave eye to eye from epistoma to distinctly above upper level of eyes; surface of concave area reticulate; lateral margins subacutely elevated from near epistoma to slightly above level of antennal insertions, summit or crest continued above as a beaded row of small tubercles to near upper level of eye; hairlike vestiture in concave area sparse, short, distinctly longer at upper margin; antennal scape with a small tuft of short setae, club 2.0 times as long as wide. Pronotum 0.70 times as long as wide; widest at base, sides arcuately converging toward rather broadly rounded anterior margin; surface reticulate, punctures very small, uniformly close, with no asperities; vestiture of short, stout scales, each about 4–6 times as long as wide uniformly distributed. Elytra 1.06 times as long as wide, 1.6 times as long as pronotum; scutellar notch very shallow; basal margins almost straight, about 10 small crenulations on each; disc occupying about 50 percent of elytra length, declivity steep, uniformly convex; striae weakly impressed, punctures rather small, close, deep; interstriae 1 as wide as striae, 2 and others twice as wide as striae, smooth (except reticulate near base on about 1–3), punctures very small, confused. Declivity steep, convex; sculpture about as on disc except central row of erect setae on each interstriae about twice as long as ground setae. Vestiture on disc of stout setae each about four to six times as long as wide, a central row of slightly longer setae evident on disc, becoming longer on declivity, each of longest setae equal in length to half distance between rows.

Distribution: Brazil: Serra do Urucum, Corumba, Mato Grosso, 25-XI-1960, K. Lenko.

Notes: The above treatment was based on the male holotype.

Chramesus peniculus Wood

Chramesus peniculus Wood, 1971:8. Holotype ♂; 30 km N Canon Zancudo, Zulia, Venezuela; USNM, Washington (References in Wood & Bright c1992:267)

Diagnosis: Male frons deeply concave to upper level of eyes, lateral margin acutely elevated, obscurely beaded; male stria punctures largely obsolete, interstria tubercles absent.

Male: Length 1.3–1.4 mm, 1.6 times as long as wide; color brown, vestiture pale. Frons broadly, deeply concave from epistoma to upper level of eyes; surface reticulate; vestiture of fine, short, sparse hair; lateral margins strongly, acutely elevated from level of antennal insertion one-third distance to upper level of eyes, crest irregular, obscurely beaded; antennal club 2.0 times as long as wide, scape with a small tuft of long, yellow hair. Pronotum 0.73 times as long as wide; as in male *solicitatus* Wood. Elytra 1.0 times as long as wide; striae impressed, punctures obscure to obsolete; interstriae slightly wider than striae, apparently smooth, punctures minute, confused, granules apparently obsolete. Declivity occupying posterior half of elytra length, convex, steep; striae and interstriae narrower than on disc. Vestiture of interstria ground cover of short, confused scales, each scale almost as wide as long, and central rows of erect bristles, bristles varying from slender to stout (on 1 individual), each 3–4 times as long as ground scales, each about two-thirds as long as distance between rows, spaced within a row by 2–4 times length of a bristle.

Female: Similar to male except frons convex, lateral margins not marked; tuft of setae absent on scape; pronotum with asperities conspicuously larger; stria punctures more distinctly impressed.

Distribution: Venezuela: 30 km N Canon Zancudo, Zulia, 4-VI-1970, 10 m, No. 522, unidentified liana, SLW.

Notes: The above treatment was based on the holotype, allotype, and 14 paratypes.

Chramesus bolivianus Schedl

Chramesus bolivianus Schedl, 1973:370. Lectotype ♂; Valle de Rio Abalo, La Paz., Bolivia 3,200 m; NHMW, Wien, present designation (References in Wood & Bright c1992:264)

Diagnosis: Distinguished from *solicitatus* Wood by the smaller size; by the more shallowly impressed male frons, with its lateral margins more weakly elevated; and by the longer, more slender setae on the pronotum and elytra.

Male: Length 2.1 mm, 1.8 times as long as wide; color dark brown, setae mostly pale, some tan setae evident in an obscure variegated pattern. Frons shallowly, broadly concave, lateral margins rather weakly elevated and ornamented on lower one-third by about five weak beads; concavity extending about four-fifths of distance to upper

level of eyes, surface coarsely reticulate below, rugose-reticulate at vertex, lateral and upper margins with small, moderately numerous tubercles; vestiture of sparse, rather long, inconspicuous coarse hair; antennal scape ornamented by about 6 comparatively short setae, club 2.0 times as long as wide. Pronotum 0.74 times as long as wide; asperities confined to lateral thirds; surface rather strongly reticulate; punctures small, poorly formed, close, most with anterior or lateral margin weakly to moderately granulate except in median area near base. Elytra about 1.3 times as long as wide, 1.8 times as long as pronotum; bases of interstriae 2–3 with about six submarginal crenulations; striae distinctly impressed, punctures small, moderately deep, close; interstriae twice as wide as striae, smooth, shining, punctures minute, mostly on margins, a central uniseriate row of moderately coarse tubercles bearing erect setae. Declivity broadly convex, rather steep; striae more deeply impressed, striae and interstriae slightly narrower than on disc. Vestiture of ground setae slender each more than half as long as erect setae on disc, and on declivity, stouter, scalelike, about one-third as long as erect setae; slender erect setae in uniseriate rows on all interstriae on disc and declivity, each about two-thirds as long as distance between rows on disc and declivity.

Distribution: Bolivia: Valley of Rio Abaho, La Paz, 30-XII-1966, 3200 m, Balogh Mahunka, ZICSI, Soil Zoological Expedition.

Notes: The above treatment was based on the “male holotype,” cited above. An apparent female holotype was deposited in the Budapest Museum. If 2 “holotypes” actually exist, as was a common practice of Schedl, I here designate the male at NHMW, Wien, as the male lectotype of *Chramesus bolivianus* Schedl, as indicated above.

Chramesus solicitatus Wood

Plate XXIV

Chramesus solicitatus Wood, 1971:8. Holotype ♂; Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:269)

Diagnosis: Male frons feebly if at all concave, concavity ending well below upper level of eyes, elevation on lateral margin beaded; stria punctures almost obsolete; antennal club stouter.

Male: Length 1.4–1.6 mm, 1.6 times as long as wide; color brown, vestiture pale. Frons broadly, shallowly concave from epistoma to well below upper level of eyes; surface reticulate; vestiture of fine, sparse, inconspicuous hair; antennal club 2.0 times as long as wide, scape with a small tuft of yellow hair. Pronotum 0.72 times as long as wide; surface reticulate, basal one-third with shallow punctures, remaining areas with fine, isolated tubercles, subasperate laterally; vestiture of short, stout, rather sparse setae. Elytra 1.0 times as long as wide, 1.4 times as long as pronotum; striae distinctly impressed, punctures rather small, distinctly impressed,

close; interstriae twice as wide as striae, smooth, shining, punctures for ground cover very small, confused, each interstriae with a central row of small, pointed tubercles. Declivity occupying posterior half, convex, steep; striae and interstriae slightly narrower than on disc, tubercles obsolete. Vestiture of ground cover of abundant small scales, each scale about 3 times as long as wide, and erect bristles (arising from tubercles), each bristle about 3 times as long as ground setae and 6–8 times as long as wide.

Female: Similar to male except frons convex, lateral margins not marked; scape without tuft of hair; pronotal asperities conspicuously larger.

Distribution: Venezuela: Campamento Rio Grande, 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 569, unidentified liana, SLW.

Notes: The above treatment was based on the holotype, allotype, and 13 paratypes.

Chramesus badius Schedl

Chramesus badius Schedl, 1951:88. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:264)

Diagnosis: This species is distinguished by the small size and rather slender body form; by the subplumose interstitial ground setae; and by the male frons having a pair of denticles at level of antennal insertion set just mesad from lateral margin.

Male: Length 1.2–1.5 mm, 1.84 times as long as wide; color brown, vestiture pale. Frons moderately concave from epistoma to upper level of eyes; surface reticulate, vestiture very short, stout, sparse; lateral margins obtusely rounded except subangulate below level of antennal insertion, a low rounded tubercle at level of antennal insertion immediately mesad of lateral margin; antennal club 2.1 times as long as wide; a small tuft of yellow hair on scape. Pronotum 0.80 times as long as wide; surface reticulate, closely, moderately punctured throughout, margins of some lateral punctures finely tuberculate; vestiture of short, moderately abundant, stout (almost scalelike) setae. Elytra 1.26 times as long as wide; striae weakly impressed, punctures rather small, impressed; interstriae about as wide as striae, almost smooth, punctures very small, confused, each with a central row of fine tubercles. Declivity occupying posterior one-third, convex, steep; striae and interstriae slightly narrower than on disc. Vestiture in ground cover of small, confused, subplumose setae, and central rows of erect bristles, each bristle twice as long as ground scales, stout, blunt, each about half as long as distance between rows, spaced within a row by length of a bristle.

Female: Similar to male except frons convex, its lateral margins not subacute.

Distribution: Brazil: Cepec, Ilheus, Bahia, II-III-1981, blacklight, Kaston; Rondon, Parana, VI-1952, No. 156, F. Plaumann.

Biology: Attracted to ultraviolet light.

Notes: The above treatment was based on the holotype and on 6 specimens from Brazil (similar to holotype but slightly smaller).

Chramesus parvus Wood

Chramesus parvus Wood, 1971:6. Holotype ♂; Rancho Grande, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:267)

Diagnosis: Lateral crest of male frons with a pair of denticles at level of antennal insertion; male frontal concavity ending below upper level of eyes; interstitial setae all in uniseriate rows of blunt bristles; pronotum without any tubercles or asperities.

Male: Length 1.3–1.4 mm, 1.7 times as long as wide; color brown, vestiture pale. Frons somewhat narrowly, moderately concave from epistoma to distinctly below upper level of eyes; surface reticulate; vestiture of short, sparse, inconspicuous hair; antennal club 2.1 times as long as wide, scape without a tuft of long hair. Pronotum 0.84 times as long as wide; surface mostly reticulate, some smooth, shining areas, punctures impressed, of variable size, not close; vestiture of short, sparse, coarse hair, without any tubercles or asperities. Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures rather coarse, deep; interstriae as wide as striae, smooth, shining, without any punctures for ground setae, a central uniseriate row of small tubercles bearing erect bristles present. Declivity confined to posterior half, convex, steep; striae, interstriae, and tubercles smaller than on disc. Vestiture of uniseriate rows of erect, blunt bristles, each bristle almost as long as distance between rows, spaced within a row by slightly less than length of a bristle.

Female: Similar to male except frons convex, lateral margins not marked.

Distribution: Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 426, *Tabebuia*, SLW.

Biology: Specimens were taken from broken twigs 2 cm in diameter.

Notes: The above treatment was based on the holotype, allotype, and 27 paratypes.

Chramesus cylindricus Schedl

Chramesus cylindricus Schedl, 1952:455. Holotype ♂; Dep. Concepcion, Santa Maria, Misiones, Argentina; NHMW, Wien (References in Wood & Bright c1992:264)

Diagnosis: Distinguished from *hylurgoides* Schedl by the smaller size; by the shallowly concave male frons, with different sculpture; by the normal eyes; and by the uniseriate declivital setae.

Male: Length 1.7 mm, 2.1 times as long as wide; color very dark brown. Frons moderately, broadly concave from epistoma to upper level of eyes, lateral margins rounded above antennal insertions; a subacute slight elevation at lateral margin below antennal insertions; concave area smooth, shining, some reticulation at epistoma and above

eyes; punctures small, almost obsolete below, larger and deeper toward vertex; vestiture of moderately long, rather numerous hair in lateral areas; eyes separated above by more than twice width of an eye. Pronotum 0.90 times as long as wide; widest at base, sides weakly arcuate on basal two-thirds, converging toward broadly rounded anterior margin; surface reticulate, punctures rather coarse, deep, close, a few in lateral areas weakly crenulate; vestiture of fine, moderately long, numerous hair. Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; basal area with about 8 submarginal crenulations behind basal row; striae not impressed, punctures rather small, impressed; interstriae almost smooth, about twice as wide as striae, most punctures replaced by a small, rounded tubercle (vestiture rather abundant). Declivity rather broadly convex, steep; striae indicated but punctures much smaller than on disc; interstriae with a row of fine punctures, no granules. Vestiture consisting of fine, short, strial hair and longer interstitial setae consisting of a central row of longer hairlike setae and sparse, slightly shorter ground cover of hairlike setae.

Female: Similar to male except frons convex, with a strong central fovea, surface reticulate.

Distribution: Argentina to Brazil.

Argentina: Misiones, Dep. Concepcion, Santa Maria (male holotype).

Brazil: Rio Grande do Sul, Torres, I-1959, K.E. Hudepohl (allotype).

Notes: The above treatment was based on the male holotype and the female allotype (Schedl 1976:65).

Chramesus macrocornis Wood

Plate XXIII

Chramesus macrocornis Wood, 1971:3. Holotype ♂; Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:267)

Diagnosis: Lateral crest of male frons with a pair of denticles at level of antennal insertions; male frontal concavity extending above upper level of eyes; interstitial setae hairlike, confused; pronotum without any tubercles or asperities.

Male: Length 2.2–2.5 mm, 2.05 times as long as wide; color very dark brown, elytra mostly brown. Frons broadly, strongly concave from epistoma to well above upper level of eyes; surface reticulate, dull, with moderately abundant, minute punctures; vestiture of minute, fine, inconspicuous hair; lateral margin armed at level of antennal insertion to epistoma by a very large, pointed denticle, margin above denticle subacutely angled; antennal club 2.1 times as long as wide. Pronotum 0.82 times as long as wide; surface reticulate, punctures rather coarse, deep, moderately close; without any tubercles or asperities; vestiture of fine, short, sparse hair. Elytra 1.4 times as long as wide, 1.8 times as long as pronotum; striae feebly impressed, punctures rather small, distinctly impressed; interstriae twice as wide as striae, surface

smooth, shining (obscurely shagreened), punctures minute, rather sparse, each with a row of fine tubercles (reduced in size toward declivity, almost absent on declivity). Declivity confined to slightly more than posterior one-third, convex, steep; strial punctures much smaller than on disc. Vestiture (both ground and erect setae) of fine hair of moderate length and abundance.

Female: Similar to male except frons convex, lateral margins not marked, a distinct transverse callus on median two-thirds at middle; lateral areas of pronotum with several subgranulate irregularities.

Distribution: Venezuela: Merida, Merida, 22-IX-1969, 1700 m, No. 14, native bamboo, SLW.

Biology: Boring in nodes of the host.

Notes: The above treatment was based on the holotype, allotype, and 56 paratypes.

Chramesus hylurgoides Schedl

Chramesus hylurgoides Schedl, 1963:214. Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:266)

Diagnosis: Distinguished from *macrocornis* Wood by the striae being not at all impressed on the disc or declivity, the punctures also are very weakly impressed; by the much less abundant, almost uniseriate declivital setae; and by the enlarged eyes that are narrowly separated above.

Male: Not seen, probably similar to male *macrocornis*.

Female: Length 2.6–2.7 mm, 2.2 times as long as wide; color dark brown, pronotum almost black. Frons convex above, with a central fovea, transversely impressed on lower third; surface weakly reticulate, punctures small, shallow, obscure above, almost obsolete below; eyes enlarged, separated above by distinctly less than width of an eye; vestiture short, sparse, inconspicuous; antennal club 2.2 times as long as wide. Pronotum 0.88 times as long as wide; widest at base, weakly arcuate and converging toward broadly rounded anterior margin; surface strongly reticulate, punctures small, shallow, some on anterior half weakly tuberculate; vestiture hairlike, rather short, moderately numerous. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; disc occupying more than basal two-thirds of elytra length; about 8 small, submarginal crenulations behind basal row; striae not at all impressed, punctures small, shallow; interstriae three times as wide as striae, almost smooth, punctures very small, those on 2 and basal half of 3 weakly tuberculate. Declivity broadly convex, very steep; smoother than on disc, punctures smaller, in rows, those of interstriae not tuberculate. Vestiture of minute strial hair and larger, rather short interstitial hair, confused on disc, uniseriate and mostly obsolete on declivity.

Distribution: Brazil: Nova Teutonia, Santa Catarina, V-1967, 300–500 m, F. Plaumann.

Hosts: Probably native bamboo.

Notes: This species was based on female syntypes. The subsequent designation of a “holotype” and an “allotype” (Schedl 1979:120) is invalid. I here designate his

female "holotype" as the lectotype of this species. His "allotype" is also a female and, hence, invalid.

Chramesus bispinus Wood

Plate XXI

Chramesus bispinus Wood, 1982:225. Holotype ♂; Tenerife, Valle del Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:264)

Diagnosis: Ground cover setae on pronotum and elytra scalelike; declivity beginning at middle of elytra length, interstriae 3 armed on middle of declivity by one pair of very large spines.

Male: Length 1.9–2.0 mm, 2.0 times as long as wide; color dark brown, vestiture forming a pattern of about 50 percent dark and 50 percent pale scales. Frons impressed on median three-fourths (narrower than other species) from epistoma to well above upper level of eyes, a transverse elevation at level of antennal insertion somewhat dividing impressed area into 2 separate concave impressions; surface reticulate, with isolated granules; vestiture rather short, coarse, moderately abundant; antennal club only slightly asymmetrical, 2.3 times as long as wide. Pronotum 0.81 times as long as wide; surface smooth, shining, punctures fine, abundant, largely concealed by vestiture of abundant ground scales, each scale about twice as long as wide (central area dark, base and sides pale); tubercles apparently absent. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; striae 1 broadly, others not impressed, punctures very small, impressed; interstriae four times as wide as striae (except 1), smooth, shining, punctures small, numerous, confused. Declivity beginning on interstriae 1 slightly anterior to middle, steep on posterior third, somewhat sulcate to spines at middle of declivity, somewhat narrowly flattened below; middle of interstriae 3 armed by one pair of very large, cylindrical, pointed spines (resembling some male *Pityogenes*) that converge caudomesad, surface of spines closely punctured and with setae to their apices; striae not evident on face of declivity below spines. Vestiture of ground cover of abundant short, interstitial scales on disc and sides, each interstriae with a central row of erect bristles, those on 1–3 rather long anterior to spines, shorter at base and sides, longer laterally toward declivity, shorter below spines on face of declivity.

Female: Similar to male except frontal impression weaker above, absent below; pronotum with more than a dozen rather coarse crenulations in lateral areas; erect interstitial setae shorter; spines as in male.

Distribution: Colombia: Tenerife, Valle del Cauca, IX-1980, 2900 m, *Passiflora mollisima*, Patricia Chacon.

Hosts: *Passiflora mollisima*.

Biology: Adult specimens were removed from the tunnels in a cut stem of the host.

Notes: The above treatment was based on the holotype, allotype, and 5 paratypes.

Chramesus dentellus Wood, n. sp.

Plate XXII

Chramesus dentellus Wood: Holotype ♂; 10 km NW Banos, Ecuador; USNM, Washington, designated below

Diagnosis: Male declivital interstriae 3 armed by three or more coarse denticles; male frons shallowly concave, lateral margin below level of antennal insertion armed by a pair of small denticles; body form rather slender, elytral setae of fine hair.

Male: Length 1.9–2.0 mm, 2.2 times as long as wide; color dark brown, vestiture mostly pale. Frons broadly, weakly concave from epistoma to upper level of eyes; surface weakly reticulate, with rather sparse, minute punctures; vestiture of short, moderately abundant, fine hair; lateral margin subacute at level of antennal insertion, armed by a blunt, moderately large tubercle between epistoma and level of antennal insertion; antennal club 2.0 times as long as wide. Pronotum 0.86 times as long as wide; surface strongly reticulate, punctures rather coarse, deep, close throughout, a few small granules on anterolateral areas. Elytra 1.4 times as long as wide, 2.0 times as long as pronotum; striae 1 weakly, others not impressed, punctures small; interstriae twice as wide as striae, almost smooth, punctures minute, moderately abundant, confused. Declivity confined to posterior one-fourth, very steep, strongly sulcate between interstriae 3; striae obsolete on declivity; interstriae 3 armed by three coarse denticles (each higher than wide) on middle half, one or two smaller denticles above or below these, a small denticle usually present at base of 2, three to five small denticles usually present in lateral areas on each side. Vestiture of fine, confused hair, somewhat longer toward declivity.

Female: Similar to male except frons modestly convex, a low median callus from central fovea to level of antennal insertion; declivity feebly impressed, spines replaced by small tubercles; vestiture shorter.

Distribution: Ecuador.

Type material: The male holotype, female allotype, and 6 paratypes were taken 10 km NW Banos, Ecuador, 26-IV-1978, ex dead Bromeliaceae flower stalk, L. & C.W. O'Brien, Marshall. The holotype, allotype, and paratypes are in U.S. National Museum, Washington.

Biology: Breeding in a Bromeliaceae flower stalk.

Chramesus subtuberculatus Eggers

Chramesus subtuberculatus Eggers, 1951:146. Holotype ♂; Colombia (Hochland von Bogota); NHMW, Wien (References in Wood & Bright c1992:269)

Diagnosis: Distinguished from *tuberculatus* (Chapuis) by the larger size; by the larger spines on declivital interstriae 3; and by the smaller strial punctures.

Male: Length 3.5 mm, 2.3 times as long as wide; color light reddish brown. Frons similar to *tuberculatus*, except costa on lateral margin subacute on its lower half, rising distinctly to a subdentate summit about half

distance to upper level of eyes, lower and more broadly rounded above; surface mostly shining below, with punctures distinct, more numerous, weakly reticulate on upper half; fine vestiture slightly more numerous. Pronotum about as in *tuberculatus* except lateral asperities slightly smaller; punctures in median area partly tuberculate. Elytra similar to *tuberculatus*, moderately sulcate on declivity; discal striae with punctures smaller; interstriae about three times as wide as striae. Declivital interstriae 3 slightly elevated, armed by six to eight subacutely pointed moderately large denticles, none longer than distance equal to its basal width; 4 and 5 each with a similar row of smaller tubercles, 6–9 unarmed; ground setae mostly restricted to declivity.

Distribution: Colombia: Bogota highlands, 1914, E. Pehlke S.

Notes: The above treatment was based on the slightly crushed male holotype from Colombia.

Chramesus tuberculatus (Chapuis)

Chramesus tuberculatus (Chapuis), 1869:47 (*Rhopalopleurus*). Lectotype ♂; Colombia [published as Nouvelle Grenada]; IRSNB, Brussels, present designation (References in Wood & Bright c1992:270)

Diagnosis: Distinguished from *dentellus* Wood by the larger size; by the male frons; by the stronger male declivital sulcus; and by the larger, more numerous declivital spines.

Male: Length 2.3–2.6 mm, 2.2 times as long as wide; color light reddish brown. Frons broadly, rather strongly concave from distinctly elevated epistoma to very slightly below upper level of eyes; lateral margins from very weak denticle at epistoma continuously costate one-half distance to upper level of eyes; surface of concavity reticulate, sparse, minute punctures obscure; vestiture rather sparse, of a mixture of fine and rather coarse hairlike setae of moderate length; eyes rather coarsely faceted for this genus; antennal club 2.3 times as long as wide, its apex narrowly rounded. Pronotum 0.80 times as long as wide, a moderate constriction just behind anterior margin; surface weakly reticulate, shining; lateral one-fourth with fine, low, subasperate crenulations, central area rather finely, shallowly, closely punctured; setae rather abundant, recumbent, weakly flattened, moderately coarse. Elytra 1.5 times as long as wide, 2.1 times as long as pronotum; crenulations on basal margins well developed, about five to seven submarginal crenulations scattered on bases of interstriae 2 to 5; striae not impressed, punctures oval, moderately deep, rather close; interstriae weakly convex, about one and one-half times as wide as striae, surface smooth, shining, weakly wrinkled between fine, setiferous punctures of erect setae; ground setae very sparse on disc, moderately abundant on declivity. Declivity moderately steep, rather strongly sulcate between left and right interstriae 3; suture feebly elevated, interstriae 2 strongly impressed, narrower than on disc, tapered to its apex, one small tubercle often near base on 1 and 2; 3 moderately elevated,

armed by six to nine coarse denticles (largest just below middle), 4–9 with a few, rounded, subdentate tubercles. Vestiture on declivity with erect setae discontinued on interstriae 1 and 2, ground setae moderately abundant, rather stout, about half as long as erect setae. Protibia with 11 socketed denticles.

Distribution: Colombia: “Colombie.”

Notes: The 2 male syntypes in the Chapuis collection were used to prepare the above treatment. The first syntype is here designated at the lectotype of *Rhopalopleurus tuberculatus* Chapuis. This specimen is slightly crushed but has all antennae and legs present.

Chramesus erinaceus Schedl

Chramesus erinaceus Schedl, 1967:7. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:265); Schedl (1978:295) described female

Diagnosis: Distinguished by the large size and stout body form; by the occurrence on the male declivity on interstriae 2 a row of basally separate very large, pointed spines, rows of smaller spines on 3 and 4; and by other characters described below.

Male: Length 2.4–2.5 mm, 1.6 times as long as wide; color dark reddish brown. Frons deeply, broadly concave from epistoma to well above upper level of eyes; concave area strongly reticulate on upper half, weakly reticulate below and subglabrous; lateral margin acute, strongly elevated from level of antennal insertions and slightly above into a large spine directed dorsad. Pronotum 0.70 times as long as wide; surface reticulate, dull, punctures small, rather numerous, none tuberculate or asperate; vestiture of 2 kinds, on discal area partly of slender, almost hairlike setae equal in length to scales, and scales (each about 4 times as long as wide) over entire surface. Elytra 1.05 times as long as wide, 1.5 times as long as pronotum; bases with 0–5 very small submarginal crenulations behind basal row; disc occupying basal two-thirds of elytral length; striae abruptly, distinctly impressed on middle two-thirds, not impressed near base or near elytral apex; interstriae weakly convex, about twice as wide as striae, almost smooth, appearing dull, punctures minute, obscure, numerous, 1 unarmed throughout, 2 armed from middle of disc to lower fourth of declivity by eight coarse, sharply pointed spines (first and last one or two of them smaller), longest equal in length to width of an interstriae, each at least twice as long as its basal width, 3 and 4 similarly armed except spines half as large as on 2, 5 and 6 each with about eight small spines on posterior half. Declivity broadly convex, gradual above, steep below, weakly impressed on 1; spines obsolete on lower fifth. Vestiture of ground cover of abundant short scales, each less than twice as long as wide, and central rows of slender bristles associated with spines, each bristle half as long as distance between rows.

Female: As in male except frons very shallowly concave; elytral spines half as large (Schedl 1978:295).

Distribution: Brazil: Nova Teutonia, Santa Catarina, X-1965, 300–500 m, F. Plaumann.

Notes: The above treatment was based on the male holotype and on the subsequently designated female allotype (Schedl 1978:295).

Chramesus spinosus Brethes

Chramesus spinosus Brethes, 1921:167. Syntypes, sex?; La Plata, Argentina; not located (Synonymy and references in Wood & Bright c1992:269)

Chramesus cristatus Schedl, 1963:213. Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil, 300–500 m; NHMW, Wien, present designation

Chramesus dentipes Schedl, 1978:295. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil, 300–500 m; NHMW, Wien (References in Wood & Bright c1992:265). *New synonymy*

Diagnosis: Distinguished from *erinaceus* Schedl by the smaller, more slender body form; by the more shallowly concave frons, with different sculpture; and by the presence of spines only on interstriae 2 and 4.

Male: Length 1.8–2.3 mm, 2.0 times as long as wide; color dark reddish brown, vestiture pale. Frons moderately concave from epistoma to upper level of eyes, sometimes weakly concave on lower fifth, reticulate above, smooth, shining and closely, finely punctured below; lateral margins moderately elevated on lower two-thirds, a weak to moderately large denticle (variable) at or immediately above level of antennal insertion; upper half of frons with several moderately long, coarse setae associated with minute punctures. Pronotum 0.71 times as long as wide; surface reticulate, punctures very shallow, rather numerous; vestiture partly of small, fine recumbent hair, and suberect scales in equal numbers, each scale about four to six times as long as wide. Elytra 1.4 times as long as wide, 2.0 times as long as pronotum; basal area with about 5 small, submarginal crenulations behind basal row; disc indefinite, occupying basal half; striae not impressed, punctures coarse, deep; interstriae slightly wider than striae, surface smooth, shining, punctures minute, obscure, rather numerous; interstriae 1 unarmed, slightly impressed from posterior third of disc to near apex on declivity, 2 in this same area armed by a row of about nine coarse, pointed spines to near apex, each spine about equal in length to width of an interstriae and twice as long as its basal width; 3, 5, and 7 unarmed; 4 armed on declivity by about eight much smaller spines (half as large as on 2); 6 with about four small, pointed tubercles. Declivity very gradual above, steep below, shallowly impressed on interstriae 1; striae distinct, interstriae as described above. Vestiture of ground cover of numerous, short, interstitial scales, each about twice as long as wide, and stout, erect bristles in central rows (not visible on basal third) varying in length from half to full width of an interstriae.

Female: Similar to male except frons almost flat, lateral elevation and spine absent; elytral spines half to two-thirds as large.

Distribution: Argentina to Brazil.

Argentina: La Plata; Buenos Aires, Pilar, X-1939, M.J. Viana.

Brazil: Nova Teutonia, Santa Catarina, X-1960, 300–500 m, F. Plaumann; Faz. Pau d'Alho-Itti, Sao Paulo, 6-VIII-1960, U. Martins.

Hosts: *Acacia cavenia*, *A. bonariensis*.

Notes: The above treatment was based on 2 males and 2 females from Argentina and on 2 males and 1 female from Brazil, including the female lectotype and and 1 male paralectotype of *cristatus* Schedl. Schedl's (1979:70) citation of a holotype of *cristatus* is not valid. I here designate that female (Schedl's "holotype") as the lectotype of *Chramesus cristatus* Schedl. Schedl's male holotype of *dentipes* was examined and was found to be a junior synonym of *spinosus*.

Chramesus phloeosinites Schedl

Chramesus phloeosinites Schedl, 1951:89. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:267)

Diagnosis: Distinguished from *erinaceus* Schedl and *spinosus* Brethes by the occurrence of a row of about 14 blunt, basally contiguous spines on interstriae 2, interstriae 3 to 7 unarmed in male, except 4 armed near its apex by five to seven small denticles.

Male: Length 2.3–2.5 mm, 2.1 times as long as wide; color yellowish brown, vestiture pale. Frons deeply concave from epistoma to slightly above upper level of eyes, upper two-thirds reticulate, lower third shining; lateral margin at level of antennal insertions acutely elevated into an obtuse, moderate tubercle; concave area with moderately abundant long setae. Pronotum 0.80 times as long as wide; surface reticulate, punctures very small, obscure, numerous; tubercles and asperities entirely absent; vestiture partly of sparse, fine, short hair, partly of numerous, erect scales, each scale about six times as long as wide. Elytra 1.5 times as long as wide, 2.1 times as long as pronotum; basal area with about 7 submarginal crenulations; disc occupying basal two-thirds of elytral length; striae not impressed, punctures large, deep; interstriae slightly wider than striae, smooth, shining, punctures small, numerous, some feebly granulate. Declivity steep, shallowly sulcate on interstriae 1, convex laterally; interstriae 2 strongly, narrowly elevated and armed by a row of fourteen to fifteen large, blunt, basally contiguous spines from base of declivity almost to apex; interstriae 4 with six or seven very small tubercles near its apex. Vestiture of short ground setae, almost hairlike on basal half of elytra becoming slender scales on declivity, and central rows of erect, stout bristles equal in length to two-thirds distance between rows.

Female: Similar to male except frons weakly convex, with a strong central fovea, surface finely rugose-reticulate, with moderately abundant, stout setae of almost uniform length; elevation on declivital interstriae 2 not as strong, shorter, armed by six or seven basally contiguous spines; interstriae 4 with six small, isolated tubercles.

HYPOBORINI

Distribution: Brazil: Nova Teutonia, Santa Catarina, XI-1940, F. Plaumann.

Notes: The above treatment was based on the male holotype from Brazil. A female from a subsequent collection was also examined. Although apparently named

from a syntypic series, the only known original specimen is a male in the Schedl Collection that was labeled by Schedl as the holotype. This holotype and Schedl's female were examined.

TRIBE HYPOBORINI

Description: Frons sexually dimorphic or not, male often impressed, female either convex or less strongly impressed; eye entire; antennal funicle 4- to 5-segmented in Neotropical species; club with up to 3 sutures indicated by rows of setae, sutures absent in some species; pronotum variously armed in restricted areas; procoxae contiguous, tarsal segment 3 narrow; scutellum not visible; crenulations on elytral bases not con-

tinued laterad from interstriae 5; postnotum fused to metatergum.

Biology: All are monogynous and phloeophagous. In *Hypoborus* and *Liparthrum* the parental gallery is a simple oval cave. In *Chaetophloeus* up to 4 short egg galleries radiate from a large nuptial chamber. Larval mines radiate from the parental chamber or egg gallery and are visible on peeled bark.

Key to the Genera of Hypoborini

- 1. Protibia strongly flattened, rather broad, lateral apical half armed by a row of 7–10 closely set socketed teeth; pronotal asperities confined to 2 or 3 paired clusters on lateral thirds, each cluster containing 1–5 asperities; funicle 5-segmented, club with or without 3 sutures *Chaetophloeus*
- Protibia slender; lateral margin armed by about 4 rather widely spaced, socketed teeth; pronotal asperities mostly on median one-third, more abundant 2
- 2(1). Antennal funicle 4-segmented, club devoid of sutures; meso- and metatibiae slender; about equal to protibia *Liparthrum*
- Funicle 5-segmented, club with three obscure sutures; meso- and metatibiae rather strongly flattened, much wider and more coarsely serrate than protibiae; host *Ficus carica* *Hypoborus*

GENUS *CHAETOPHLOEUS* LeConte

Chaetophloeus LeConte, 1876:382. Type-species: *Hylesinus hystrix* LeConte, monobasic (Synonymy and references in Wood & Bright c1992:271–274)

Renocis Casey, 1886:257. Type-species: *Renocis heterodoxus* Casey, monobasic

Pseudocryphalus Swaine, 1917:20. Type-species: *Pseudocryphalus brittaini* Swaine = *Renocis heterodoxus* Casey, original designation

Diagnosis: Pronotal asperities restricted to 2 small, paired clusters in lateral areas (each cluster with 1–3 asperities); interstitial setae abundant, confused; protibiae broad.

Description: Length 1.1–2.5 mm, 1.4–2.1 times as long as wide; color brown to black, vestiture pale. Frons sexually dimorphic, male more strongly impressed,

female often convex; eye elongate, sinuate to feebly emarginate; antennal scape rather short, funicle 5-segmented, club slender to subcircular, usually marked by 3 transverse, aseptate sutures (absent in 1 species); pronotum wider than long, armed by 2 paired clusters of asperities (South American species) on lateral areas; elytral bases armed by crenulations from suture to striae 4, one submarginal crenulation at base of interstriae 1; tarsal segment 3 slender; vestiture of plumose to scale-like setae, often in various patterns of dark and pale scales.

Distribution: Canada to Brazil, Wood & Bright (1992: 271–274) record 23 species, 2 of which occur in South America.

Biology: All species are monogynous and phloeophagous. Most species breed in twigs or branches less

than 5 cm in diameter, although 1 species has been taken in boles larger than 30 cm in diameter. The male initiates the new attack and forms a large nuptial chamber at and below the cambium area and he may begin 1–4 short egg galleries. When he is joined by a female,

she then completes 1–4 egg galleries. Eggs are placed individually in niches and packed in frass. Larval mines radiate from the parental chambers. Adult and larval tunnels usually engrave the wood rather deeply. More than one generation each year is common.

Key to the Species of *Chaetophloeus*

- 1. Erect interstitial bristles (in rows) short, stout, each about twice as long as wide, about one-third as long as distance between rows; eyes smaller, separated above by 2.4 times width of an eye; emargination of male frons not as deep (occupying about one-fifth distance to upper level of eyes); male frons more evenly, more broadly, more extensively concave; Brazil (Ceara); host?; 1.2–1.4 mm *braziliensis* (Blackman)
- Erect interstitial bristles longer, more slender, each at least six times as long as wide, about one-half as long as distance between rows; eyes larger, separated above by 1.9 times width of an eye; emargination of male epistoma very deep (about two-fifths distance to upper level of eyes; male frons more narrowly concave, largely confined to upper half; Venezuela; *Mimosa*; 1.3–1.8 mm *andinus* Wood

Chaetophloeus braziliensis (Blackman)

Plate XXV

Chaetophloeus braziliensis (Blackman), 1940:398 (*Renocis*). Holotype ♀; Ceara, Brazil; USNM, Washington (References in Wood & Bright c1992:271)

Diagnosis: Distinguished from *andinus* Wood by the smaller average size; by the shorter, stouter, erect interstitial scales; by the smaller more finely faceted eyes; and by the very different male frons.

Male: Length 1.2–1.4 mm, 1.7 times as long as wide; color brown, vestiture pale. Frons broadly, moderately concave from broadly emarginate epistoma to well above upper level of eyes, epistomal emargination extending 16 percent of distance toward upper level of eyes; surface almost smooth, shining, with fine, isolated granules; vestiture in central area of fine, rather sparse hair of moderate length, lateral and upper margins with a row of rather coarse, long setae; anterior angle of mandible extended into a moderately long spine; antennal club 1.9 times as long as wide, sutures obscurely indicated by rows of setae, almost obsolete. Pronotum 0.95 times as long as wide; surface reticulate, punctures fine, rather close; asperities in 2 pair of clusters in lateral areas, 1 or 2 slender crenulations in each cluster; vestiture of 2 kinds of short setae in about equal numbers, 1 type slender, almost hairlike, second type stout, each about 4 times as long as wide. Elytra 1.2 times as long as wide, 1.8 times as long as pronotum; striae weakly impressed, punctures small, distinct; interstriae about twice as wide as striae, almost smooth, shining, each with a central row of granules, with a row of short, stout, recumbent setae on each margin, granules bearing erect bristles, each bristle about twice as long as wide, about one-third as long as distance between rows, spaced within a row by length of a bristle. Declivity confined to slightly less

than posterior half, convex, steep; sculpture about as on disc except tubercles obsolete.

Female: Similar to male except frons convex above, modestly, transversely impressed on lower half, setae short, stout, uniformly distributed; epistomal margin almost straight.

Distribution: Brazil: Ceara, 1947, D. da Rocha.

Notes: The above treatment was based on 10 specimens bearing identical data to the type series that were compared directly by me to the type series.

Chaetophloeus andinus Wood

Plate XXIV

Chaetophloeus andinus Wood, 1971:9. Holotype ♂; 3 km E Lagunillas, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:271)

Diagnosis: Distinguished from *braziliensis* (Blackman) by the larger average size; by the longer, more slender, erect, interstitial setae; by the larger, more coarsely faceted eyes; and by the very different male frons.

Male: Length 1.3–1.8 mm, 1.7 times as long as wide; color brown, vestiture pale. Frons shallowly, somewhat narrowly subconcave to upper level of eyes; epistoma deeply emarginate, about two-fifths distance toward upper level of eyes; surface apparently subgranular, punctures obscure, vestiture coarse (subplumose), moderately long in central area, much longer at margins; anterior angle of mandible extended into a spine; antennal club 2.0 times as long as wide, sutures clearly indicated by aseptate sutures and rows of setae. Pronotum 0.63 times as long as wide, about as in *braziliensis*. Elytra 1.2 times as long as wide; striae weakly impressed, punctures small, distinct; interstriae twice as wide as striae, surface almost smooth, without a row of tubercles, ground setae as in *braziliensis*, erect bristles each about four

times as long as wide, half as long as distance between rows, spaced within a row by less than length of a bristle. Declivity confined to posterior one-third, convex, moderately steep on basal two-thirds, very steep below; striae and interstriae sculpture similar to disc.

Female: Similar to male except frons broadly convex, epistoma weakly, broadly emarginate, vestiture on frons much shorter; asperities on pronotum of same number but larger.

Distribution: Venezuela: 3 km E Lagunillas, Merida, 12-I-1970, 1000 m, No. 256, *Mimosa*, SLW.

Biology: Specimens were removed from the phloem of small branches.

Notes: The above treatment was based on the holotype, allotype, and 26 paratypes.

GENUS *LIPARTHURUM* WOLLASTON

Liparthrum Wollaston, 1854:294. Type-species: *Liparthrum bituberculatum* Wollaston, original designation (Synonymy and references in Wood & Bright c1992:274–275)

Erineosinus Blackman, 1920:53. Type-species: *Erineosinus squamosus* Blackman, monobasic

Phloeochilus Schedl, 1953:292. Type-species: *Phloeochilus palaquius* Schedl, original designation

Phloeotrypetus Wood, 1960:16. Type-species: *Phloeotrypetus palauensis* Wood, original designation

Dacryophthorus Schedl, 1971:281. Type-species: *Dacryophthorus brincki* Schedl, original designation

Trypanophellos Bright, 1982:166. Type-species: *Trypanophellos necopinus* Bright, original designation

Diagnosis: Distinguished from *Chaetophloeus* by the smaller size; by the more slender body form; by the 4-segmented antennal funicle; by the unsegmented antennal club; by the anteromesal position of pronotal asperities; and by other characters.

Description: Length 0.75–1.2 mm, 2.2–2.4 times as long as wide; color dark brown. In these 2 South American species the frons is sexually dimorphic, broadly concave in male, convex in female; eye oval, short, entire; antennal scape elongate, funicle 4-segmented, club aseptate, without indications of sutures. Pronotum about as long as wide, with minute asperities on median area from near anterior margin almost to base. Scutellum not visible. Elytra with basal margins armed by six pair of crenulations from suture to striae 5; striae not impressed, punctures distinct or not; declivity convex, steep, unarmed.

Distribution: There are 36 species recorded worldwide (Wood & Bright c1992:274–279). Of these, 10 occur in North America and the Antilles Islands, 2 occur in South America.

Biology: Most species are phloeophagous where a large cave-type parental chamber is formed in the cambium area. On the margins of this chamber egg niches are formed where eggs are placed individually in niches and packed in frass. One Asiatic species was removed from fallen fruit on the rainforest floor.

Key to the Species of *Liparthrum*

- 1. Pronotum larger, subquadrate in outline; striae punctures not clearly evident, almost obsolete; declivital interstriae 2 with erect, scalelike setae similar to those on 1 and 3; half of impressed area on male frons above upper level of eyes; body color reddish brown; Venezuela; *Carapa guianensis*; 0.9–1.2 mm **carapae** Wood
- Pronotum smaller, subtriangular in outline; striae punctures rather large, impressed; erect setae on declivital interstriae 2 slender, appearing as short, stout hair, those on 1 and 3 clearly scalelike; less than one-fourth of impressed area on male frons above upper level of eyes; body color dark brown; Venezuela (Merida); small, unidentified, resinous shrub; 0.75–0.85 mm **meridensis** Wood

Liparthrum carapae Wood

Plate XXV

Liparthrum carapae Wood, 1971:9. Holotype ♂; Campamento Rio Grande, 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:276)

Diagnosis: Larger than *meridensis* Wood and reddish brown in color; striae punctures not clearly evident, almost obsolete; declivital interstriae 1–3 with similar sculpture and vestiture, 2 with erect scales as on 1 and 3; half of male frontal concavity above upper level of eyes.

Male: Length 0.9–1.2 mm, 2.4 times as long as wide; color reddish brown, vestiture pale. Frons concave from

epistoma to vertex, almost half of concavity above upper level of eyes; surface shining, punctures minute, concave area almost glabrous, a brush of long hair on upper margin. Pronotum 1.0 times as long as wide, subquadrate in outline; surface subreticulate, with minute, isolated asperities on median area almost to base; vestiture of fine recumbent hair and sparse erect, slender scales. Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures obscure to obsolete, recognized by insertion of striae hair where punctures should occur; interstriae minutely irregular, not smooth, each with a row of small setiferous granules. Declivity confined to posterior one-third of elytra length, convex, steep; striae and interstriae slightly narrower than

on disc, interstitial granules slightly larger. Vestiture of short, recumbent strial hair and a central uniseriate row of erect scales on each interstriae, each scale almost as wide as long, about half as long as distance between rows, spaced within a row by length of a scale.

Female: Similar to male except frons convex, vestiture short, sparse, inconspicuous; pronotum with asperities much larger and more conspicuous.

Distribution: Venezuela: Campamento Rio Grande, 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 580, *Carapa guianensis*, SLW.

Biology: Specimens attacked a recently felled bole of the host about 40 cm in diameter. Cave-type parental chambers were in the cambium area, with eggs placed individually in niches and packed in frass around the peripheral margin of the chamber. New larval mines were just beginning and showed on peeled bark.

Notes: The above treatment was based on the holotype, allotype, and 210 paratypes.

Liparthrum meridensis Wood

Plate XXVI

Liparthrum meridensis Wood, 1971:10. Holotype ♂; 5 km E Lagunillas, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:278)

Diagnosis: Smaller than *carapae* Wood and dark brown in color; erect setae on declivital interstriae 2 slender, almost hairlike, those on 1 and 3 scalelike; male frontal concavity extending only slightly above upper level of eyes.

Male: Length 0.75–0.85 mm, 2.2 times as long as wide; color very dark brown, vestiture pale. Frons shallowly concave from eye to eye from epistoma to upper level of eyes; surface reticulate, punctures minute; vestiture on lateral and dorsal margins longer and more numerous. Pronotum 0.86 times as long as wide, subtriangular in outline; surface subreticulate, with rather abundant granules or small asperities on median two-

thirds to base. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures moderately large, rather deep; interstriae slightly narrower than striae, smooth, each with a row of setiferous punctures. Declivity confined to slightly more than posterior one-fourth of elytra length; convex, steep; sculpture about as on disc. Vestiture of uniseriate rows of short, recumbent strial hair and uniseriate rows of erect interstitial scales, each scale slightly longer than wide except almost hairlike on posterior half of 2, each slightly shorter than half distance between rows, spaced within a row near base by twice length of a scale, on declivity by less than length of a scale.

Female: Similar to male except frons convex, vestiture short, sparse, inconspicuous.

Distribution: Venezuela: 5 km E Lagunillas, Merida, 12-I-1970, 1000 m, No. 238, a small resinous shrub, SLW.

Host: Small, abundant, resinous, roadside shrub.

Biology: Galleries appeared to be similar to those of *carapae*.

Notes: The above treatment was based on the holotype, allotype, and 68 paratypes.

GENUS *HYPOBORUS* ERICHSON

Hypoborus Erichson, 1836:62. Type-species: *Hypoborus ficus* Erichson, monobasic (Synonymy and references in Wood & Bright c1992:279–281)

Diagnosis: Closely allied to *Liparthrum* but distinguished by the 5-segmented antennal funicle and by the clearly marked sutures on the club.

Notes: This genus, represented by *H. ficus* Erichson, is widely distributed in southern Europe, Asia Minor, northern Africa, and Madagascar. It has not yet been reported from North or South America, but the frequency with which the host, *Ficus carica* (cultivated fig), is grown in these areas suggests that its introduction there is only a matter of time.

SUBFAMILY SCOLYTINAE

The subfamily Scolytinae as presented here is based on Wood (1978, 1982, 1986), and Wood & Bright (c1992). It differs significantly from that of other previous authors.

The Scolytinae have the basal margins of the elytra forming a straight, transverse line across the body. These basal margins are usually unarmed [except armed by crenulations in South American *Cnemonyx* species allied to *galeritus* (Eichhoff)]. In several tribes (some Scolytini, Ctenophorini, Cryphalini) these margins may be weakly elevated on a continuous, smooth line. The scutellum is usually large and flat, although it may be absent or variously modified in some Xyleborini. The pronotum is usually weakly to more strongly declivous on the anterior half and is usually armed by asperate crenulations,

particularly on the median half. The head is usually partly to entirely concealed from the dorsal aspect and is slightly narrower than the pronotum. The protibiae are usually more slender than in Hylesiniinae and, in Scolytini, have secondarily lost their socketed denticles. Scales or deeply divided setae are an uncommon feature of this subfamily, although both features occur here in some tribes.

Inbreeding polygyny, with apparent male haploidy and dwarfism, and the xylomycetophagous habit, are much more common and widespread than in Hylesiniinae.

A key to the tribes of Scolytinae is included under "Family Scolytidae" following the introductory section of this volume.

TRIBE SCOLYTINI

Description: Lateral margins of pro- and (usually) metatibiae unarmed by spines or socketed denticles except for a single, apical spinelike process on lateral apical angle that curves toward and extends beyond inner apical angle. Recent research in Ctenophorini indicates that socketed tibial denticles were present, but were lost secondarily in that tribe from which the Scolytinae may have been derived (Jordal 1998). Lateral margins of pronotum subacutely elevated and costate. Antennal funicle 7-segmented; sutures of antennal club strongly procurved or partly to entirely obsolete. Pleural suture descending subvertically from pleural wing process to groove receiving groove and flange on costal margin of elytra, here this suture turns abruptly and follows this groove caudad to the metapleural coxal process. Male frons variously impressed, female frons convex. Eye oval and entire. Scape short to elongate; club strongly flattened.

Distribution: Four genera are known. Three of the 4 genera are restricted to South and Central America, the Antilles islands, and the southern, subtropical tip of Florida (USA). A limited segment of the character diversity of *Scolytus* extended into North America and a still more limited segment reached Asia and Europe where a substantial, secondary radiation occurred. Of the 118 species of *Scolytus* listed by Wood & Bright (c1992: 321–382) 33 species, exhibiting great character diversity, occur in South America, while 60 species, of much more limited character diversity, occur in Asia, Europe, and northern Africa. It is quite obvious that the tribe originated in South America and had a long history of endemism there before migrating into north temperate areas.

Biology: Three of the 4 genera of Scolytinae are strictly phloeophagous. The *Camptocerus* have adopted a unique form of xylomycetophagy. All species of the tribe practice monogyny, except that the *dimidiatus* species group of *Scolytus* are regularly bigynous.

Key to the Genera of Scolytini
(Adapted from Wood 1986:58)

- 1. Scutellar area of interstriae 1 not depressed, scutellum flush (even) with surface of elytral bases, basal margins of elytra with a fine raised line (some *Cnemonyx* with crenulations in place of line), outline of anterior margins form a continuous, straight, transverse line with scutellum; ventral profile of abdomen ascending gradually 2
- Scutellum depressed, subtriangular, apically (posteriorly) pointed, elytral bases depressed in scutellar area, appearing emarginate in median area, ventral profile of abdomen usually ascending abruptly at segment 2 3

- 2(1). Antennal club usually with two or three sutures clearly marked by setae; scutellum small, longer than wide, often convex; apical margin of meso- and metathoracic tibiae commonly bearing tubercles on anterior edge in addition to inner and outer apical spines; usually more coarsely sculptured; phloeophagous; USA (Florida) and Mexico to Argentina; 1.0–3.9 mm . . . **Cnemonyx**
- Antennal club with suture 1 (only) marked internally by a partial septum; scutellum flat, 1.5 or more times as wide as long; meso- and metathoracic tibiae acutely margined on apical anterior edge, without supplemental denticles; usually very finely sculptured; xylomycetophagous; Nicaragua to Argentina; 2.6–8.5 mm **Camptocerus**
- 3(1). Basal portion of costal margin of elytra deeply, broadly excised, metepisternum conspicuously expanded into this notch; abdomen abruptly flexed upward at posterior margin of segment 2; phloeophagous; Mexico (Oaxaca) and Cuba to Argentina; 1.6–3.5 mm **Scolytopsis**
- Costal margin of elytra normal (straight) and overlapping metepisternum; abdomen flexed upward from anterior margin of segment 2; phloeophagous; North and South America, Europe, N Asia, N Africa; 1.3–5.5 mm **Scolytus**

GENUS *CNEMONYX* EICHHOFF

Cnemonyx Eichhoff, 1868:150. Type-species: *Cnemonyx galeritus* Eichhoff, monobasic (Synonymy and references in Wood & Bright c1992:313–318)

Ceratolepis Chapuis, 1869:52. Type-species: *Ceratolepis jucundus* Chapuis, monobasic

Loganius Chapuis, 1869:52. Type-species: *Loganius flavicornis* Chapuis, monobasic

Minulus Eggers, 1912:206. Type-species: *Minulus barbatus* Eggers = *Cnemonyx galeritus* Eichhoff, monobasic

Coptodryas Schedl, 1948:262. Type-species: *Coptodryas hylurgoides* Schedl, monobasic, preoccupied by Hopkins 1914:10, 54

Coptosomus Schedl, 1952:363. Type-species: *Coptodryas hylurgoides* Schedl, replacement name for *Coptodryas* Schedl

Diagnosis: Distinguished from *Camptocerus* by the presence of two or three sutures on the antennal club, indicated both externally and internally; by the scutellum that is longer than wide and is often convex; by the apical meso- and metathoracic tibiae commonly bearing tubercles on the anterior edge (as well as the usual apical mesal and lateral spines); and by the phloeophagous habit.

Description: Length 1.0–3.9 mm, 1.8–2.8 times as long as wide; color brown to black, vestiture sparse, short, of

scales and/or hair. Frons moderately to strongly concave in male, convex to shallowly impressed in female, its vestiture varying from absent to an elaborate brush of hair; antennal scape elongate, funicle 7-segmented, club flattened, with 2 or 3 sutures indicated internally and externally. Pronotum large, broad, unarmed. Scutellum flat to convex, usually longer than wide, its surface about equal to level of elytra. Elytral bases marked by a fine raised line (broken into marginal crenulations in some species); sculpture moderate, declivity gradual; abdomen rising slightly to moderately to meet apex of elytra.

Distribution: Mexico and S Florida (USA) to Argentina. Wood & Bright (c1992:313–318) list 49 species, 28 of which were reported from South America.

Biology: The monogynous, phloeophagous species bore biramous parental tunnels in the phloem of the limbs and boles of their hosts. These are characteristic for each species and may be either longitudinal (rare) or transverse (most species) with respect to the grain of wood in the host. Larval mines radiate through the phloem from the parental mines.

Key to the Species of *Cnemonyx*

1. Antennal club clearly marked by three sutures, sutures indicated by rows of definite, closely set, long hair; basal margins of elytra marked by a continuous costa; Venezuela to Brazil and Argentina; 2.2–2.4 mm **flavicornis** (Chapuis)
- Antennal club obscurely marked by suture 1, internal septum sometimes indicated, clearly marked on 2 and 3, club often asymmetrical, sometimes without definite rows of long hair 2
- 2(1). Discal interstriae (at least on basal half) with punctures (and setae, when present) clearly confused, striae punctures usually narrower, interstriae wider; mostly larger species 3
- Discal interstriae with punctures and setae (when present) uniseriate from base to declivity, striae usually wider, interstriae narrower; body often conspicuously more slender; mostly smaller species 12

SCOLYTINI

- 3(2). Antennal club more nearly symmetrical, all setae on club hairlike; male frons more shallowly, usually less extensively impressed 4
- Antennal club strongly asymmetrical, most setae on antennal club short, palmately divided; male frons more strongly, more extensively impressed 7
- 4(3). Frons with transverse carina at epistoma (not at level of antennal insertions); frontal vestiture more uniformly distributed, of somewhat uniform length, color pale 5
- Frons with primary transverse carina above epistoma situated at level of antennal insertions, a much weaker carina sometimes at epistomal margin; frontal vestiture organized into 2 areas separated by a median subglabrous line, at least part of setae much longer, of golden color 6
- 5(4). Male frons with a short, weak, transverse carina on epistoma and a strong, long, transverse carina slightly above level of antennal insertion, area above upper carina broadly, shallowly concave to well above upper level of eyes; female frons convex above, transversely impressed on lower half and with a weak median carina on lower third; Costa Rica and Panama to Venezuela and Bolivia; tree limb; 2.0–2.4 mm *panamensis* (Blandford)
- Male frons with a short, transverse carina at level of antennal insertion, epistomal margin unarmed, area above carina flattened below to weakly convex above; Colombia to Venezuela; *Protium*, *Virola*; 1.9–2.4 mm *protivorus* Wood
- 6(4). Epistoma modestly, transversely carinate on median one-fifth (or slightly more) more weakly elevated toward lateral extremities, frons shallowly, narrowly impressed almost to upper level level of eyes, surface reticulate-granulate, vestiture of fine, sparse, uniformly distributed hair; pronotum and elytra glabrous; Bolivia; 2.5 mm *glaber* (Eggers)
- Epistoma weakly, transversely carinate, an additional weak, transverse crest at level of antennal insertions, upper two-thirds shallowly concave in male, convex in female; pronotum and elytra covered by moderately abundant setae; Venezuela to Bolivia; *Trichilus propinguus*; 2.0–2.5 mm *vestitus* (Eggers)
- 7(3). Male frons broadly concave to upper level of eyes, epistoma flat, reticulate, without a transverse epistomal carina; discal interstriae subreticulate, punctures small, confused, vestiture of fine, moderately long hair; color dark brown 8
- Male frons variously concave, with a distinct, transverse epistomal carina; setae on discal interstriae minute to obsolete 9
- 8(7). (Based on female) Frons shallowly concave from epistoma to distinctly below upper level of eyes, without a weak, median carina at vertex; surface reticulate on and near epistoma, becoming rugose-reticulate on upper half of frons to vertex; interstitial punctures on disc about half as large as those of striae, uniseriate except slightly confused at and near base of 1 and 2, vestiture of rather stout, recumbent setae, their length on declivity equal to diameter of a strial puncture, twice as long near base on 1 and 2, setae uniseriate except weakly confused at base of 1 and 2; Brazil (Amazonas); 2.5 mm *amazonicus* (Eggers)
- (Based on male) Frons broadly, moderately concave from epistoma to slightly above upper level of eyes, a short, low, median carina at vertex; surface rugose-reticulate from epistoma to vertex; discal striae with punctures smaller, not as deep, interstriae three times as wide as striae; interstitial punctures on disc small, deep, close, confused, vestiture of fine, confused hair; Brazil (N. Fribourg); about 2.8 mm *jucundus* (Chapuis)
- 9(7). Smaller species; male frons moderately concave from near epistoma to well above upper level of eyes, a straight, transverse carina on epistoma with a series of transverse wrinkles above (dorsal) carina; interstriae with confused, subrugose punctures on basal half, each with a uniseriate row of minute granules on declivity, minute, hairlike setae arise from punctures; Honduras to Colombia; 1.8–2.3 mm *maculicornis* (Blandford)

- Larger species; male epistoma with a rather strongly elevated, transverse carina, shallowly concave on lower half to as much as upper level of eyes; interstriae on basal one-third with fine, uniseriate or confused punctures, becoming subcarinate to carinate on posterior half, glabrous 10
- 10(9). Interstriae on declivity more rounded, not subcarinate, tubercles larger, closer; declivity and upper two-thirds of frons strongly rugose-reticulate; interstitial setae on declivity small, each about four to six times as long as wide; French Guyane; 2.5–2.8 mm *niger* (Eggers)
- Interstriae on declivity weakly subcostate, tubercles on crests smaller, not as close; upper declivity and upper frons finely, strongly reticulate; interstitial setae on declivity more slender and smaller to obsolete 11
- 11(10). Male frons more strongly concave to upper level of eyes, epistomal carina procurved; interstitial punctures on basal third of elytra much smaller, their anterior margin feebly elevated, never subcrenulate; punctures on pronotum slightly smaller, not as deep, longitudinal striations less conspicuous; striae punctures on declivity weak to obscure, rugose-reticulation covering entire declivity, interstriae obscurely subcostate, tubercles minute to obscure; Costa Rica to Colombia and Venezuela; *Vismia*; 3.5–3.9 mm *insignis* Wood
- Male frons less strongly, more broadly concave almost to upper level of eyes, epistomal carina straight; interstitial punctures on basal third coarser, almost uniseriate, their margin mostly elevated (a weak crenulation); punctures on pronotum larger, deeper, impressed, rugose-reticulation restricted to apical third of declivity; Bolivia; 2.5 mm *boliviae* (Blackman)
- 12(2). Basal margins of elytra a simple raised line, not noticeably broken into crenulations, without any submarginal crenulations (at bases of interstriae 2–5) 13
- Basal margins armed by a more or less definite row of crenulations, bases of interstriae 2 to 5 with several conspicuous, submarginal crenulations 17
- 13(12). Frons with a strongly developed transverse carina (male) or callus (female) at level of antennal insertion, flattened on a more limited area, vestiture sparse (but rather long in median area) . . . 14
- Frons without a transverse carina or callus in either sex (an epistomal callus sometimes present), more extensively flattened (at least on lower half) 15
- 14(13). Male frontal carina rounded, distinctly procurved, in female rather poorly developed; frontal vestiture above carina extending almost to upper level of eyes on median two-thirds in both sexes; pronotum longitudinally etched, dull on anterior two-thirds, punctures larger; interstitial punctures on disc distinctly smaller than those of striae, their anterior margins feebly elevated; Mexico (Veracruz) to Costa Rica; *Vismia*; 1.6–1.7 mm *minusculus* (Blandford)
- Male frontal carina straight, more acutely elevated in both sexes; frontal vestiture above carina ending well below upper level of eyes on median one-third; pronotum conspicuously etched on less than anterior half, punctures smaller; interstitial punctures on disc almost as large as those of striae, their bases subvulcanate (anterior margins conspicuously elevated; Bolivia to Venezuela; *Trichilus propingua*; 1.8–2.3 mm *rugulosus* (Eggers)
- 15(13). Larger species; pronotum and elytra glabrous; elytral surface on disc smooth, shining, striae not at all impressed, punctures small, distinct; interstitial punctures minute, simple, each about one-fourth as large as those of striae; Colombia; *Cespedesia macrophylla*, *Dialyanthera otoba*; 2.1–2.5 mm *furvescens* Wood
- Smaller species; rows of interstitial setae present at least on declivity; elytral surface minutely irregular, striae at least feebly impressed, interstitial punctures larger, at least two-thirds as large as those of striae 16
- 16(15). Body stouter, less than 2.3 times as long as wide; color almost black; pronotum longitudinally etched, punctures elongate; interstitial punctures much shorter, somewhat semirecumbent; male frontal vestiture shorter, less abundant over a smaller area; Venezuela; *Vismia*; 1.5–1.8 mm *vismiocolens* Wood

- Body more slender, 2.7 times as long as wide; color brown; pronotum reticulate, punctures oval; interstitial setae erect, much longer; male frons with abundant pubescence to upper level of eyes; Brazil (Santa Catarina); 1.7–1.9 mm *difformis* (Schedl)
- 17(12). Body stouter, 1.8–2.1 times as long as wide; crenulations on basal margins of elytra rather poorly formed, almost forming a continuous line; color usually brown 18
- Body rather slender, 2.5–2.6 times as long as wide; marginal and submarginal crenulations sometimes well-formed, separate; color usually almost black 20
- 18(17). Interstitial setae conspicuously flattened, each about six times as long as wide, about two-thirds as long as distance between rows; male frons subconvexly impressed on median three-fourths, pubescence attaining upper level of eyes; Brazil (Santa Catarina) to Argentina; 1.2–1.4 mm *minor* Schedl
- Interstitial setae almost hairlike; male frons flattened to well above upper level of eyes, setae extending to upper level of eyes 19
- 19(18). Pronotum dull, strongly reticulate, punctures rather shallow, spaced by 1–3 diameters of a puncture; interstitial setae of slender, recumbent hair, each about two-thirds as long as distance between rows; Brazil (Santa Catarina); 0.9–1.1 mm *creber* Schedl
- Pronotum shining, smooth, punctures rather coarse, close, deep, spaced by one-third to full diameter of a puncture; interstitial setae recumbent, hairlike, each equal in length to almost one-half distance between rows; Brazil (Santa Catarina); 1.8–2.1 mm *errans* (Blandford)
- 20(17). Superficially resembling *flavicornis* except entirely unrelated (antennal club with only one poorly formed suture); submarginal crenulations at elytral bases absent, marginal row rather poorly formed; interstitial punctures uniseriate to base, surface on disc shagreened, on declivity dull with interstriae more narrowly convex; pronotum reticulate on anterior third, punctures on basal third small, oval, rather close; a minute transverse carina at level of antennal insertions (somewhat resembling *flavicornis* but much smaller, lower); Brazil; 2.3 mm *longicollis* (Blandford)
- Smaller, more slender species; submarginal crenulations at elytral bases usually conspicuous 21
- 21(20). Submarginal crenulations at bases of elytra poorly developed, obscure (about two to four clearly visible); interstitial setae mostly restricted to declivity, uniseriate, short, longest setae equal in length to one-third distance between rows; interstitial tubercles absent; Brazil (Bahia); 1.5 mm *acuminatus* Schedl
- Submarginal crenulations at bases of elytra coarse, numerous; interstitial setae extending from base to declivity, more numerous, longer, some tubercles usually present; color dark brown to almost black 22
- 22(21). Interstitial setae hairlike, each almost as long as distance between rows; elytral declivity more gradual, striae more distinctly impressed, tubercles smaller, more sharply pointed; Chile; *Colliguaja intergerrima*; 1.5–1.6 mm *galeritus* Eichhoff
- Interstitial setae flattened, scalelike, each about eight times as long as wide and almost as long as distance between rows; elytral declivity steeper, striae weakly impressed, interstitial tubercles slightly larger 22
- 23(22). Diameter of punctures on pronotum much smaller than striae punctures, shallow; frontal impression narrower, not as deep, setae longer, more numerous; Argentina (Buenos Aires); 1.0–1.1 mm *brevisetosus* Schedl
- Diameter of punctures on pronotum about equal to striae punctures, deeper; impression on frons wider, deeper, setae less numerous, shorter; Bolivia; 1.3 mm *indisiosus* Schedl

Cnemonyx flavicornis (Chapuis)

Cnemonyx flavicornis (Chapuis), 1869:53 (*Loganius*). Lectotype ♂; Cumana, Venezuela; IRSNB, Brussels (References in Wood & Bright c1992:315)

Loganius scaliger Hagedorn, 1910:5. Holotype ♂; Argentina; Hamburg Museum, lost

Cnemonyx vianai Schedl, 1951:289. Syntypes, sex?; Tigre, Buenos Aires, Argentina; NHMW, Wien, and Viana Collection

Diagnosis: This is the only reported South American species in this genus possessing 3 strongly procurved rows of setae on the antennal club. From the closely allied *opacus* Wood it is distinguished by the fine, rather numerous granules on the impressed area of the frons in both sexes; by the more narrowly convex declivital interstriae 2–4 with serrations finer, closer; and by the rugose-reticulate surface of discal striae and interstriae almost attaining the base of the disc.

Male: Length 2.2–2.4 mm, 2.25 times as long as wide; color dark reddish brown. Frons shallowly concave on its median two-thirds from level of antennal insertion to slightly above upper level of eyes, concave area rather closely, finely tuberculate, lateral areas and above reticulate, rather coarsely, shallowly punctured; a subacute transverse carina at level of antennal insertion on median one-fourth; vestiture of stout, rather abundant, moderately long bristles; segments of antennal funicle ornamented by long setae; club with three sutures indicated by strongly procurved rows of setae. Pronotum 1.0 times as long as wide; surface smooth, shining, slight reticulation on anterior one-fourth; punctures moderately fine, almost round, rather close, spaced by distances equal to one to two diameters of a puncture; almost glabrous. Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; striae not impressed at base, moderately impressed by base of declivity, punctures rather small, moderately deep, their interiors reticulate-granulate to base; interstriae twice as wide as striae, mostly wrinkled but shining on basal third, dull and reticulate-granulate behind, some reticulation at margins almost to base, punctures confused, moderately coarse and deep near base, small and uniseriate near declivity, anterior margins of punctures rounded, subcrenulate at base, of uniseriate tubercles before declivity. Declivity convex, rather steep; striae narrower, deeper than on disc, punctures more obscure; striae and interstriae more strongly reticulate-granulate, interstriae 1–9 each with a uniseriate row of fine, close, pointed tubercles to apex, punctures not indicated. Vestiture of uniseriate rows of very short, fine bristles each equal in length to less than one-fifth distance between rows, spaced within a row by slightly more than length of a bristle.

Female: Similar to male except frontal impression weak to absent, transverse epistomal carina half as long; reticulation on pronotum often extending to middle of pronotum length; declivital interstriae less strongly acute, tubercles smaller.

Distribution: Venezuela to Bolivia and Argentina.

Argentina: "Argentina" (type of *scaliger* Hagedorn).

Bolivia: San Esteban, 49 km N Santa Cruz, 7-XII-1959, 1120 ft., R. Cumming.

Brazil: Jatahy, Goyas.

Paraguay: Carumbe in San Pedro, 1-II-8-III-1966, I-1971, R. Golbach; San Bernardino, K. Friebrig.

Venezuela: Cumana in Sucre, Funk.

Notes: The above treatment was based on the male lectotype of *flavicornis* (Chapuis), 1 male paralectotype from Venezuela, 1 male from Bolivia, 1 female from Brazil, and on 4 males and 1 female from Paraguay.

Cnemonyx glaber (Eggers)

Cnemonyx glaber (Eggers), 1929:64 (*Loganius*). Holotype ♀?; E Bolivia; USNM, Washington (References in Wood & Bright c1992:316)

Diagnosis: Frons somewhat similar to *flavicornis* (Chapuis); distinguished from *vestitus* (Eggers) by the glabrous pronotum and elytra, and by the very different frons.

Female (?): Length 2.5 mm, 2.1 times as long as wide; color very dark brown, almost black. Frons flattened to feebly concave on a triangular area from epistoma three-fourths distance toward upper level of eyes; epistoma somewhat weakly carinate laterally, median fifth moderately carinate; surface rugose-reticulate above level of antennal insertions, area immediately above epistoma rather coarsely, deeply punctured; vestiture rather sparse on impressed area, uniformly distributed, rather fine, of moderate length; antennal club rather large, somewhat symmetrical, sutures not evident, setae of fine hair. Pronotum 1.0 times as long as wide; surface shining, punctures coarse in lateral areas, moderately coarse on anterior third of median area, gradually becoming smaller until rather fine at base, some punctures with partial, longitudinal strigose lines extending from them; subglabrous. Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; striae distinctly, narrowly impressed, punctures small, distinctly impressed; interstriae about three times as wide as striae, shining, irregular, with numerous, confused punctures, these moderately coarse near base (as large as striae punctures), less than half as large on disc. Declivity occupying posterior half of elytral length, rather gradual; sculpture similar to disc except weakly to moderately reticulate. Glabrous.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the holotype, presumably a female, from Bolivia.

Cnemonyx vestitus (Eggers)

Plate XXVIII

Cnemonyx vestitus (Eggers), 1929:59 (*Loganius*). Lectotype ♂; E Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:35 (References in Wood & Bright c1992:318)

Diagnosis: Male frons with a weak, transverse callus well above level of antennal insertion; concavity shallow, extending to upper level of eyes, setae of equal distribution; interstitial setae on disc confused, coarse, recumbent.

Male: Length 2.0–2.5 mm, 2.04 times as long as wide; color reddish brown except elytra dark reddish brown. Frons broadly, shallowly concave on upper two-thirds, a subcarinate transverse callus (with median summit) slightly above level of antennal insertion; epistoma abrupt, obscurely elevated; surface reticulate-granulate, punctures fine, obscure; vestiture uniformly distributed, of moderate, almost uniform length from epistoma to upper level of eyes; setae on funicle present, modestly developed. Pronotum 1.0 times as long as wide; surface rugose-reticulate on anterior one-third, transcending to reticulate by base; punctures small, close, moderately deep, spaced by about half diameter of a puncture, some punctures in obscure lines, separated by obscure, longitudinal ridges; setae on anterior third longer, coarser, on posterior third short, sparse, inconspicuous. Elytra 1.12 times as long as wide, 1.2 times as long as pronotum; scutellum twice as wide as long; striae weakly impressed, punctures small, impressed, some partly confluent; interstriae more than twice as wide as striae, shining, with numerous, small, confused, subcrenulate tubercles, each about one-fifth as wide as an interstriae (poorly formed near base); vestiture of recumbent, coarse, confused setae of moderate, uniform length, each seta equal in length to about two-thirds width of an interstriae. Declivity convex, moderately steep; striae wider than on disc, punctures obsolete; interstriae narrower than on disc, tubercles smaller, less numerous, obsolete or nearly so toward apex; vestiture similar to disc.

Female: Similar to male except frons uniformly convex, callus absent, punctures more distinctly impressed, posterior half of pronotum almost smooth.

Distribution: Bolivia to Venezuela.

Bolivia: "Ostbolivia."

Venezuela: 17 km SE Miri, Barinas, 17-XII-1969, 150 m, No. 195, *Protium*, SLW; 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 562, *Trichilia propingua*, SLW.

Biology: Limbs 3–10 cm in diameter on recently felled trees were attacked. Parental galleries were in the cambium area and were transverse and biramous. Larval mines were short, tortuous, and primarily in the phloem.

Notes: The above treatment was based on 17 specimens from Venezuela. One of these was compared by me directly to the male holotype.

Cnemonyx panamensis (Blandford)

Plate XXVII

Cnemonyx panamensis (Blandford), 1896:129 (*Loganius*). Lectotype ♂; Tole, Chiriqui, Panama; BMNH, London, present designation (References in Wood & Bright c1992:317)

Loganius setulosus Eggers, 1929:62. Holotype ♂; E Bolivia (Cochabamba, Woytkowski); NHMW, Wien (References in Wood & Bright c1992:317). *New synonymy*

Loganius similis Eggers, 1929:63. Lectotype ♂; E Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:30 (References in Wood & Bright c1992:317). *New synonymy*

Diagnosis: Distinguished from *vestitus* (Eggers) by the more extensively, shallowly concave frons to well above

upper level of eyes; by the broad, transverse carina well above level of antennal insertion, setae in concave area of unequal length and distribution; interstitial setae on disc confused, much shorter.

Male: Length 2.0–2.4 mm, 2.1 times as long as wide; color reddish brown, elytra much darker, almost black. Frons broadly, moderately concave on upper two-thirds, margins rather abrupt, lower margin formed by a broad, subacute transverse carina, shallowly concave from carina to slightly above upper level of eyes, concave area rugose-reticulate, punctures fine, deep, close; shining and punctured below carina; epistomal margin abrupt; vestiture of concave area hairlike, longer in dorsolateral areas (separated at median line), extending three-fourths distance toward carina, shorter, less abundant below; setae on funicle sparse. Pronotum 1.0 times as long as wide; surface smooth, shining, except rugose-reticulate on anterior one-fourth, punctures moderately coarse, close, most elongate, several near center longitudinally confluent; coarse hair limited to anterior one-fourth. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; striae narrowly, abruptly, distinctly impressed, punctures obscure, indistinctly impressed; interstriae three times as wide as striae, subshining, with numerous, small, confused tubercles; vestiture recumbent, coarse, confused, each seta equal in length to one-third to one-half width of an interstriae. Declivity broadly convex, rather steep; striae and interstriae narrower than on disc; interstriae with granules almost obsolete.

Female: Similar to male except frons convex above, transverse carina absent, a weak median carina below ending in a small median tubercle on epistoma.

Distribution: Costa Rica and Panama to Venezuela and Bolivia.

Bolivia: "Ostbolivia" (label on type is Cochabamba, Woytkowski).

Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 415, tree limb, SLW; 8 km W Bumbum, Barinas, 11-II-1970, 150 m, *Protium*, SLW.

Hosts: *Vismia guianensis* (in Costa Rica).

Biology: Transverse, biramous parental galleries were formed in phloem of a broken limb 10 cm in diameter.

Notes: The above treatment was based on the male lectotype and on over 80 specimens from Costa Rica and Panama, on the male lectotype of *similis* Eggers from Bolivia, and on 46 specimens from Venezuela, 1 male of which was compared directly to the holotype of *similis*. I compared the holotype of *setulosus* Eggers directly by to my specimens from Venezuela and Central America. Although considerable variability is seen in the specimens at hand, it is presumed that only species exists. The male holotype of *setulosus* has the pronotum punctures smaller and more strongly strigose than those from elsewhere. Specimens from Venezuela (Rancho Grande) have the interstitial setae on the disc distinctly longer than those from Central America and Bolivia.

Cnemonyx protivorus Wood

Cnemonyx protivorus Wood, 1979:137. Holotype ♂; 40 km SE Socopo, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:317)

Diagnosis: Distinguished from *panamensis* (Blandford) by the flat male frons, transverse carina almost on the epistoma; and by the coarse, confused, moderately long interstitial setae on the disc.

Male: Length 1.9–2.4 mm, 2.1 times as long as wide; color very dark reddish brown, almost black. Frons about as in female *panamensis*, but convex on more than upper half, somewhat flattened below, upper margin of epistoma bearing on median one-third an acutely elevated, transverse carina; surface rugose-reticulate above, transcending to weakly reticulate at carina; vestiture resembling *panamensis* except very much less abundant; brush on funicle weak. Pronotum very similar to *vestitus* (Eggers), surface shining except subreticulate on anterior one-fourth. Elytra very similar to *vestitus* except recumbent interstitial setae shorter, each equal in length to about one-half width of an interstriae.

Female: Similar to male except frontal setae much more abundant, much longer, reddish yellow in color; interstitial crenulations slightly larger.

Distribution: Colombia to Venezuela.

Colombia: Campo Capote 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 603, *Vismia*, SLW.

Venezuela: 8 km SE Bumbum, Barinas, 11-II-1970, 150 m, No. 312, *Protium*, SLW; 17 km SE Miri, Barinas, 17-XII-1969, 150 m, No. 195, *Protium*, SLW; 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 256, *Protium*, SLW.

Biology: Specimens were removed from phloem of branches of recently felled trees. The galleries were as in *vestitus*.

Notes: The above treatment was based on the type series of 143 specimens from Venezuela, and on 4 specimens from Colombia.

Cnemonyx amazonicus (Eggers)

Cnemonyx amazonicus (Eggers), 1929:60 (*Loganius*). Lectotype ♂; Santarem, Amazonas, Brazil; USNM, Washington, designated by Anderson & Anderson 1971:4 (Synonymy and references in Wood & Bright c1992:313)

Ceratolepis amazonicus Schedl, 1952:349. Syntypes, sex?; Santarem, Amazonas, Brazil; NHMW, Wien, preoccupied by Eggers 1929:60, Synonymy and references in WEB 1992

Diagnosis: Distinguished from *jucundus* (Chapuis) by the less strongly concave frons; by the larger, almost uniseriate interstitial punctures; and by the shorter interstitial setae.

Male(?): Length 2.5 mm, 2.04 times as long as wide; color dark reddish brown. Frons broadly, shallowly concave from epistoma seven-eighths distance to upper level of eyes, with no indication of either a transverse or a longitudinal carina; surface reticulate on lower third, becoming rugose-reticulate above to vertex, punctures

small, shallow, obscure, moderately abundant; vestiture moderately abundant, of stout, blunt setae of moderate length (length equal to combined width of six facets of eye), shorter on vertex. Pronotum 1.0 times as long as wide; surface very finely, weakly, longitudinally etched, becoming rugose-reticulate on anterior fourth; punctures oval in shape, each about half as large as a stria puncture, spaced by 1–2 diameters of a puncture; vestiture restricted to anterior third, of minute hair, one arising from each puncture. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; striae distinctly impressed, punctures moderately large, distinctly, individually impressed (no apparent confluence); interstriae about twice as wide as striae, punctures at least half as large as those of striae near base, about one-third as large at base of declivity, uniseriate except confused at base of 1 and 2. Declivity occupying posterior half of elytra length; striae narrower than on disc, punctures becoming obscure near apex; interstriae narrower than on disc, becoming narrowly subcarinate, punctures reduced to a single row on crests; posterolateral margin weakly, finely serrate. Vestiture of semirecumbent interstitial setae, short on declivity (equal to about diameter of a stria puncture), longer on disc (equal to width of an interstriae); interstitial setae in uniseriate rows except very slightly confused at base of 1 and 2, rather stout (not hairlike).

Distribution: Brazil: Santarem (Amazonas), B.v. Bodenmeyer, Eggers Collection 1948.

Notes: The above treatment was based on the Eggers holotype, presumably a male, from Brazil. The Schedl syntypes came from the Eggers Collection, as noted on the labels.

Cnemonyx hylurgoides (Schedl)

Cnemonyx hylurgoides (Schedl), 1948 (1949):262 (*Coptodryas*). Holotype, sex?; Santa Catarina, Brazil; NHMW, Wien, lost except for a slide mount of 1 antenna (Synonymy and references in Wood & Bright c1992:313, 316)

Diagnosis: The holotype has been lost except for the slide mount of one antenna. From my examination of the antenna this species is placed in the genus *Cnemonyx* near *amazonicus* Eggers (Wood 1982:395, 399).

Female: Length 2.0 mm, 2.66 times as long as wide (Schedl 1948:262–263). The original description is quoted as follows:

“Piceous, 2.0 mm long, 2.66 times as long as wide. Pronotum subglabrous, elytra with short setae on the interspatial punctures and granules only.

“Front aplanate to subimpressed not quite to the eyes, subshining, minutely punctulate, indistinctly finely punctured, on the aplanate portion apparently rugosely punctured and with a brush of very short erect yellowish pubescence, a fringe of short pale hairs along the epistomal margin.

“Pronotum about as long as wide, widest before the base, sides distinctly divergent on the basal fifth, thence

convergent in a fairly straight line to the unarmed and narrowly rounded apex; rather feebly convex, subshining and remotely finely punctured in front, ground sculpture minutely punctulate, more shining behind, the punctures much larger, therefore appearing more crowded, the interspaces polished. Scutellum very small.

“Elytra somewhat wider (22.5:21), and 1.8 times as long as the pronotum, cylindrical and parallel-sided to far beyond the middle, moderately broadly and feebly angulately rounded behind, declivity commencing somewhat behind the basal half, evenly convex; disc striate-punctate, striae rather feebly impressed, strial punctures of moderate size, shallow and very closely placed, interstices narrow, each with a rather regular row of punctures, which soon are replaced by setose granules and these becoming somewhat larger on the declivity, the striae more shallow and the strial punctures indistinct on the latter, the interspatial punctures and granules short, semierect reddish scale-like hairs.”

Distribution: Brazil: Santa Catarina.

Notes: The description of the type is too general to permit identification at this time, but my examination of the slide mount of the antenna clearly places this species in *Cnemonyx* in the species group of *amazonicus* Eggers. The discrepancy in body proportions (2.66 by Schedl, 2.5 by me) is accounted for by Schedl's inclusion of the head and space between the scutellum and pronotum in Schedl's measurements.

Cnemonyx jucundus (Chapuis)

Cnemonyx jucundus (Chapuis), 1869:53 (*Ceratolepis*). Holotype ♂; Nova-Fribourg, Brazil; IRSNB, Brussels (References in Wood & Bright c1992:316)

Diagnosis: Distinguished from *maculicornis* Blandford and *insignis* Wood by the distinctive frons, as described below; and by the discal interstriae having confused punctures that lack tubercles and bear very fine, moderately long hair.

Male: About 2.8 mm (type crushed), about 2.0–2.1 times as long as wide (estimated); color dark brown. Frons broadly, moderately concave from epistoma to slightly above upper level of eyes, margins rounded except subacute near epistoma, median line on vertex at margin of impression with an obscure, short, low, median carina; epistoma broadly flattened on median two-thirds, its surface moderately rugose-reticulate, becoming more coarsely rugose-reticulate above to vertex; punctures small, close, moderately deep; vestiture of rather short, semirecumbent, moderately coarse hair of moderate abundance; fringe of setae on funicle sparse, short. Pronotum 0.85 times as long as wide; surface weakly etched by subreticulation except reticulate on anterior fourth; anterior third and lateral areas with very fine, rather short hair. Elytra about 1.3 (estimated) times as long as wide, 1.3 times as long as pronotum; striae narrowly, moderately impressed, punctures small, weakly impressed,

obscured through confluence; interstriae more than three times as wide as striae, surface subreticulate, almost smooth, punctures small, moderately deep, close, confused, anterior margin of some punctures feebly subcrenulate, without any true granules; vestiture of fine, confused hair, most appearing equal in length to at least one-half width of an interstriae, coarser setae in posterolateral areas. Declivity convex, rather steep; striae and interstriae 1–3 about as on disc, no granules.

Distribution: Brazil: “N. Fribourg, Deyr.”

Notes: The above treatment was based on the male holotype.

Cnemonyx maculicornis (Blandford)

Plate XXVII

Cnemonyx maculicornis (Blandford), 1896:127 (*Ceratolepis*). Lectotype ♀; Tole, Panama; BMNH, London, designated by Wood 1982:399 (References in Wood & Bright c1992:316)

Diagnosis: Antennal club asymmetrical, at least part of setae on club appearing palmately divided; male frons moderately concave, median area on lower one-third transversely wrinkled; interstitial setae confused, minute, surface apparently reticulate.

Male: Length 1.8–2.3 mm, 2.05 times as long as wide; color dark brown. Frons broadly, moderately concave from epistoma to well above upper level of eyes, its margins rather narrowly rounded; surface of concavity rugose-reticulate above, almost smooth at epistoma, punctures rather fine, moderately close, median area below transversely wrinkled just above a moderate, transverse, epistomal carina (on median half), vestiture of fine, rather long, moderately abundant hair uniformly distributed; funicular brush poorly developed; many setae on club appearing palmately divided. Pronotum 0.76 times as long as wide; surface obscurely reticulate on anterior third, mostly smooth behind, punctures moderately small near center, larger laterally and behind, much smaller in anterior areas; glabrous except for fine, short hair near anterior margin. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; scutellum small, as wide as long; striae moderately impressed, punctures rather small, weakly impressed, on 1 and 2 mostly confluent; interstriae twice as wide as striae, distinctly convex, surface rugose-reticulate, fine, confused punctures, each puncture with its anterior margin narrowly, acutely, rather finely crenulate. Declivity convex, gradual, commencing at middle of elytral length; interstriae almost as narrow as striae, their tubercles forming a uniseriate row of fine, pointed tubercles on 1 to 9, 9 slightly elevated. Interstitial vestiture of confused, very short, stout, sparse setae, length of a seta about equal to diameter of a strial puncture (less than one-fifth as wide as an interstriae).

Female: Similar to male except frons almost flat to upper level of eyes, wrinkles obscure on lower area, epistomal transverse carina weak; pronotum almost without reticulation; interstitial crenulations slightly larger; costal margin near apex more strongly serrate.

Distribution: Honduras to Colombia.

Colombia: Campo Capote 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 594, *Virola*, SLW.

Biology: Transverse, biramous, parental galleries were made in the cambium area of a recently cut limb 10 cm in diameter.

Notes: The above treatment was based on 23 specimens from Colombia and on 26 from Central America. Two of the Costa Rican specimens I compared directly to the female lectotype.

Cnemonyx niger (Eggers)

Cnemonyx niger (Eggers), 1933:13 (*Ceratolepis*). Holotype ♀; St. Laurent du Maroni, French Guyane; MNHN, Paris (Synonymy and references in Wood & Bright c1992:317)

Camptocerus nigricans Schedl, 1962:485, an unneeded replacement name

Diagnosis: Distinguished from *boliviae* (Blackman) and *insignis* Wood by; the smaller size; by the rugose-reticulate upper frons and lower declivity, with the declivital interstriae rounded (not subcarinatae) and the tubercles larger and closer.

Female: Length 2.5–2.8 mm, 2.0 times as long as wide; color black. Frons shallowly concave on lower half of area below upper level of eyes, convex above; median two-thirds of epistomal margin weakly elevated to form a weak straight carina; lower half of impressed area smooth, shining and with close, rather coarse punctures, upper area to vertex strongly rugose-reticulate, punctures obscure to obsolete; sparse, short stout setae on lateral areas and all of upper half. Pronotum 0.92 times as long as wide, widest at base, arcuately converging to narrowly rounded anterior margin; surface on anterior fourth reticulate, becoming minutely, longitudinally etched to base; punctures rather coarse, becoming smaller on anterior third; glabrous. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; disc occupying basal half; striae rather strongly, narrowly impressed, interstriae on disc three to four times as wide as striae, convex, mostly smooth, shining, punctures rather coarse and confused on basal half of disc and without crenulations. Declivity moderately steep; striae rather strongly impressed, striae with obscure punctures, about as wide as interstriae, interstriae with minute subtuberculate crenulations below, slightly larger near base of declivity. Vestiture mostly confined to declivity, consisting of uniseriate rows of short, recumbent, stout setae, each seta 4–6 times as long as wide. Antennal club rather strongly asymmetrical, with numerous small palmately divided scales.

Distribution: French Guyane: St. Laurent du Maroni, 1909, E. Le Moul.

Notes: The above treatment was based on the female holotype and 3 female paratypes of *Ceratolepis niger* Eggers. Schedl (1962:485) erroneously transferred this species to *Camptocerus* and renamed it *C. nigricans*, an unneeded name.

Cnemonyx boliviae (Blackman)

Cnemonyx boliviae (Blackman), 1943:378 (*Camptocerus*). Holotype ♂; San Borja, Beni, Bolivia; USNM, Washington (References in Wood & Bright c1992:314)

Diagnosis: Distinguished from *insignis* Wood by the more broadly, less strongly impressed male frons; by the straight epistomal transverse carina; by the more coarsely punctured, subcrenulate interstitial punctures on the basal half of the elytra; and by the more strongly impressed striae punctures on the declivity, with the rugose-reticulate surface sculpture restricted to the lower third of the declivity.

Male: Length about 2.5 mm, about 2.0 times as long as wide (paratype specimen broken); color black. Frons impressed on lower two-thirds, a very feeble median carina on upper half of impressed area, rather coarsely, closely punctured on middle third; transverse epistomal carina straight, less strongly elevated than in *insignis*; vestiture fine, rather short, uniformly distributed; antennal club shape and palmate setae about as in *insignis*. Pronotum broken in specimen at hand; as in *insignis* except punctures slightly larger and longitudinal striations more conspicuous. Elytra resembling *insignis* except striae punctures distinctly larger, deeper, distinctly impressed to apex, surface rugose-reticulate only on lower third of declivity; interstriae subcarinate on posterior two-thirds of elytral length, their crests weakly subserrate, basal third broadly convex, punctures moderately impressed, mostly uniseriate, each about half to two-thirds as large as those of striae, anterior margin of most elevated, some obscurely subcrenulate. Pronotum and elytra subglabrous.

Distribution: Bolivia: San Borja, Dep. Beni, VIII-1925, G.L. Harrington.

Notes: The above treatment was based on 1 broken male paratype.

Cnemonyx insignis Wood

Plate XXVI

Cnemonyx insignis Wood, 1969:9. Holotype ♂; Moravia, Cartago, Costa Rica; USNM, Washington (References in Wood & Bright c1992:316)

Diagnosis: Distinguished by the large size, black color, and absence of interstitial setae; and by the distinctive frons.

Male: Length 3.5–3.9 mm, 2.04 times as long as wide; color black. Frons moderately concave on median two-thirds from epistoma to distinctly below upper level of eyes; surface dull, coarsely rugose-reticulate above level of antennal insertion, smooth, shining below, median half of epistoma armed by a rather strongly elevated procurved carina; concave area with fine, close, deep punctures, vestiture dark, erect, rather short, mostly in concave area; funicular brush weak, club strongly asymmetrical, with palmate setae. Pronotum 0.94 times as long as wide; posterior two-thirds almost smooth, shining, anterior

one-third reticulate to longitudinally etched, punctures small, mostly oval; glabrous. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; scutellum twice as wide as long; striae moderately impressed, punctures small, distinct; interstriae convex, about twice as wide as striae, smooth, shining, punctures small, confused, without tubercles, glabrous. Declivity broadly convex, occupying posterior half of elytral length; striae slightly wider than on disc, interstriae much narrower, narrowly convex, a uniseriate row of small punctures at summit on each; striae reticulate. Glabrous.

Female: Similar to male except discal interstriae partly to entirely reticulate; abdominal terga 7 and 8 give only reliable external method of determining sex.

Distribution: Costa Rica to Colombia and Venezuela.

Colombia: Campo Capote 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 592, *Virola*, SLW.

Venezuela: 13 km SW El Vigía, Merida, 22-X-1969, 100 m, No. 77, *Virola*, SLW; 20 km SW El Vigía, Merida, 21-X-1969, 50 m, No. 148, *Virola*, SLW.

Biology: Parental galleries were longitudinal and biramous in the phloem in recently felled or broken limbs and logs 10 to more than 30 cm in diameter.

Notes: The above treatment was based on the type series of 7 specimens from Costa Rica, 49 from Colombia, and 60 from Venezuela.

Cnemonyx rugulosus (Eggers)

Plate XXVIII

Cnemonyx rugulosus (Eggers), 1929:64 (*Loganius*). Holotype ♀; E Bolivia; USNM, Washington (References in Wood & Bright c1992:317)

Diagnosis: Frons with a transverse carina in both sexes, male frons feebly impressed; interstitial setae on disc in uniseriate rows, almost scalelike.

Male: Length 1.8–2.3 mm, 2.04 times as long as wide; color very dark brown, almost black. Frons with an acute transverse carina on median half slightly above level of antennal insertion; area above carina flattened to feebly impressed on median half from carina to half distance to upper level of eyes; surface strongly reticulate, punctures rather fine, deep, close; vestiture rather sparse and moderately long and stout in marginal areas, longer, finer, and more abundant in median area above carina. Pronotum 1.04 times as long as wide; surface smooth, shining behind, subreticulate and somewhat rugulose on anterior fourth, punctures moderately large, deep, spaced by 1–3 diameters of a puncture behind, somewhat enlarged and obscure on anterior fourth; glabrous, except sparse, stout setae on anterior one-fourth. Elytra 1.35 times as long as wide, 1.35 times as long as pronotum; striae weakly impressed, punctures small, distinctly impressed; interstriae twice as wide as striae, shining, punctures uniseriate, almost as large as those of striae, their anterior margins distinctly elevated (rounded, not crenulate), each tubercle bearing an erect, flattened seta (each about

4–6 times as long as wide). Declivity restricted to posterior 40 percent of elytral length, convex, rather steep; surface finely rugose-reticulate; striae and punctures obscure, wider than on disc; interstriae much narrower than on disc, each with a row of small, rounded tubercles, setae as on disc.

Female: Similar to male except frontal carina only subacute (a strong callus in some specimens), vestiture less abundant, finer; pronotum often with longitudinal strigose lines associated with punctures.

Distribution: Bolivia to Venezuela.

Bolivia: "Ostbolivia."

Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 561 in *Tetragastria mucronata*, No. 562 in *Trichilia propingua*, SLW.

Biology: In phloem of recently cut limbs of the hosts.

Notes: The above treatment was based on 43 specimens from Venezuela, 1 of which I compared directly to the male holotype from Bolivia.

Cnemonyx furvescens Wood

Cnemonyx furvescens Wood, 1979:137. Holotype ♀; Campo Capote 27 km NE Montoya, Santander, Colombia; USNM, Washington (References in Wood & Bright c1992:315)

Diagnosis: Allied to *rugulosus* (Eggers) but easily distinguished by the very different frons as described below; by the glabrous elytra; and by the minute, uniseriate interstitial punctures.

Male: Length 2.1–2.5 mm, 2.1 times as long as wide; color very dark brown, shining. Frons with epistomal margin forming a subacute carina on median half; surface broadly, moderately concave from epistoma to upper level of eyes on an area slightly narrower than distance between eyes; surface reticulate above, smooth below, punctures fine, deep, close, uniformly distributed, slightly larger above eyes; vestiture fine, short, rather sparse, confined to concave area. Pronotum 1.0 times as long as wide; surface almost smooth, minutely, obscurely, longitudinally etched; punctures small, oval, moderately close; glabrous. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; striae distinctly impressed, punctures very small, spaced within a row by two to five diameters of a puncture; interstriae four to five times as wide as striae, slightly convex, smooth, brightly shining, glabrous, punctures minute, uniseriate. Declivity occupying posterior half of elytra length, convex, moderately steep; interstitial punctures replaced on declivity by minute, poorly formed, uniseriate rows of granules. Minute remnants of fine setae on some interstriae.

Female: Similar to male except epistomal carina weaker (a strong callus in some specimens), frontal setae more numerous, slightly longer; interstitial granules on declivity more definite, slightly larger.

Distribution: Colombia: Campo Capote 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 632, *Cespedesia macrophylla*, *Dialyanthera otoba*, SLW.

Biology: Specimens were removed from phloem of limbs of recently broken trees.

Notes: The above treatment was based on the entire type series of 23 specimens.

Cnemonyx vismiacolens Wood

Plate XXIX

Cnemonyx vismiacolens Wood, 1979:138. Holotype ♀; Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:318)

Diagnosis: Allied to *rugulosus* (Eggers) but distinguished by the very different frons as described below; by the smaller pronotal punctures; and by other details described below.

Male: Length 1.5–1.8 mm, 2.3 times as long as wide; color black. Frons broadly, weakly, shallowly impressed on median two-thirds of lower half; surface rugose-reticulate on upper half and sides below, almost shining in central area below; epistoma slightly elevated, smooth (not at all carinate); vestiture stout, moderately short, rather abundant almost to upper level of eyes. Pronotum 0.95 times as long as wide; anterior third rugose-reticulate, transcending to longitudinal etching before middle, posterior areas mostly smooth, shining with slight, very weak etching; punctures small, oval; glabrous. Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; striae feebly impressed, punctures small, shallow, spaced within within a row by one to two diameters of a puncture; interstriae about three times as wide as striae, very weakly convex, surface shining, minutely irregular, punctures small, uniseriate (almost as large as those of striae), their anterior margin not elevated. Declivity occupying posterior half of elytral length; convex, moderately steep; striae more distinctly impressed than on disc; interstriae 1 partly, longitudinally etched, each interstriae with a row of small, poorly formed granules. Vestiture of rows of erect, slender, interstitial scales, each scale 6–8 times as long as wide.

Female: Similar to male except frons less distinctly impressed, vestiture more abundant; pronotal etching extending to base; declivital tubercles on interstriae slightly larger, more fully formed.

Distribution: Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 432, Guttiferae sp., SLW.

Biology: Removed from transverse, biramous parental galleries in phloem of recently broken limbs.

Notes: The above treatment was based on the type series of more than 200 specimens.

Cnemonyx difformis (Schedl)

Cnemonyx difformis (Schedl), 1951:74 (*Loganius*). Syntypes, sex?; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, and Plaumann Collection (References in Wood & Bright c1992:314)

Loganius cirratus Nunberg, 1958:480, 482. Holotype ♂?; Santa Catarina, Brazil; IZW, Warsaw

Diagnosis: Allied to *rugulosus* (Eggers), although the relationship is remote. Distinguished by the uniquely

punctured and pubescent frontal elevation at level of antennal insertion; by the abundant pubescence on the frons; by the largely reticulate pronotum (on anterior two-thirds); by the slender body; and by other characters described below.

Female: Length 1.7–1.9 mm, 2.7 times as long as wide; color brown. Frons almost flat from epistoma to upper level of eyes, with a punctured and pubescent transverse, subcarinate elevation on median third at level of antennal insertion (above epistoma); surface reticulate above and at sides, apparently shining below; vestiture of abundant, erect, coarse setae of uniform length. Pronotum 1.0 times as long as wide; surface reticulate on at least anterior two-thirds, smooth to weakly etched behind, punctures fine, moderately close; a few setae on anterior one-fourth. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures moderately large, impressed; interstriae twice as wide as striae, smooth, shining, each with a row of punctures slightly smaller than those of striae, punctures at base normal, those near declivity with anterior margin elevated into a small tubercle. Declivity restricted to posterior third of elytra length; convex, steep; striae narrowly, distinctly impressed; interstriae somewhat convex, each with a row of moderately large tubercles (smaller on 1); costal margin near suture coarsely, rather strongly serrate. Vestiture of uniseriate rows of slender bristles, each almost 10 times as long as wide on disc and declivity.

Distribution: Brazil: Nova Teutonia, Santa Catarina, 1-IV-1947, 300–500 m, F. Plaumann; Telemaco Borba, 1-XII-2003, Klabin Papel e Celulose forest, sulcatol trap in *Pinus taeda* stand, C.A.H. Flechtmann.

Notes: The above treatment was based on 6 specimens from Brazil, 1 female of *Loganius difformis* Schedl I compared directly to the type.

Cnemonyx minor Schedl

Cnemonyx minor Schedl, 1951:75. Syntypes, sex?; Santa Catarina, Brazil; NHMW, Wien, and Plaumann Collection (References in Wood & Bright c1992:316)

Diagnosis: This species, *creber* Schedl, and *errans* (Blandford) are allied to one another and are distinguished by the somewhat crenulate anterior margin of the elytra and strong submarginal crenulations. This species is distinguished by the wider, more nearly scale-like interstitial setae; and by the more strongly impressed male frons.

Male: Length 1.2–1.4 mm, 2.0 times as long as wide; color dark brown. Frons shallowly, broadly, subconcavely impressed from level of antennal insertion to upper level of eyes, sparsely, finely punctured on margins, more densely on lower third, small, central area smooth, shining; epistoma smooth, shining, slightly elevated, a smooth, shining, oval callus occupying median one-third; rather coarse, moderately long setae rather abundant on impressed area. Pronotum 0.90 times as long as wide; surface

strongly reticulate interiorly, weakly toward base, punctures moderately coarse, rather deep, spaced by one-half to twice diameter of a puncture; vestiture sparse, of rather long, flattened, somewhat coarse setae. Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; basal margins with crest distinctly marked into crenulations, interstriae 2–5 with a combined total of at least 12 submarginal crenulations; striae feebly impressed, punctures distinctly impressed, spaced within a row by one-half diameter of a puncture; interstriae slightly wider than striae, surface almost smooth, each with a uniseriate row of fine, rather close punctures. Declivity occupying slightly less than posterior half, convex, steep; striae and interstriae narrower than on disc, punctures with their anterior margin slightly elevated (not tuberculate). Vestiture of uniseriate rows of suberect, flattened interstitial setae, each seta eight to 10 times as long as wide, as long as distance between rows, spaced within a row by two-thirds length of a seta.

Female: Similar to male except frons flattened, not impressed, less closely punctured, callus smaller, less definite.

Distribution: Brazil: Nova Teutonia, Santa Catarina, VII-1944, F. Plaumann; Rondon, Parana, 24°38' B, 54°07' L, 1952, 500 m, F. Plaumann.

Notes: The above treatment was based on 2 paratypes and on 11 other specimens from Brazil.

Cnemonyx creber Schedl

Cnemonyx creber Schedl, 1951:76. Syntypes ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, and Plaumann Collection (References in Wood & Bright c1992:314)

Diagnosis: Distinguished by the strongly reticulate pronotum; by the slender, almost hairlike interstitial setae; and by the unique male frons.

Male: Length 0.9–1.1 mm, 2.0 times as long as wide; color very dark brown. Frons flattened from epistoma to well above upper level of eyes; epistoma indistinctly elevated, callus poorly defined; middle third (actually slightly below middle one-third) densely pubescent, resembling velvet (setae very short, of uniform length), lateral setae longer and extending higher on sides, areas above and below more finely, less densely punctured. Pronotum 0.82 times as long as wide; surface strongly reticulate, punctures rather small, not sharply defined; apparently glabrous. Elytra 1.14 times as long as wide, 1.2 times as long as pronotum; basal margins subcrenulate, submarginal crenulations coarse, few in number; striae distinctly impressed, punctures small, distinct; interstriae slightly wider than striae, each with a uniseriate row of fine tubercles. Declivity occupying posterior half of elytra length, convex, rather steep; striae slightly deeper, striae and interstriae slightly narrower than on disc. Vestiture of uniseriate rows of recumbent setae, each seta rather short (length equal to one-half distance between rows), slender, spaced within row by length of a seta.

Female: Similar to male except frons less extensively flattened (convex above upper level of eyes), setae more generally distributed without dense, short velvet.

Distribution: Brazil: Nova Teutonia, Santa Catarina, 1949, X-1951, F. Plaumann.

Notes: The above treatment was based on 1 male paratype, and on 1 other male and 2 females from Brazil.

Cnemonyx errans (Blandford)

Cnemonyx errans (Blandford), 1896:127 (*Ceratolepis*). Lectotype ♂; "Mexican" (actually Brazilian) tobacco refuse intercepted at Paris; BMNH, London, designated by Wood 1972:192 (References in Wood & Bright c1992:314)

Ceratolepis brasiliensis Schedl, 1936:104. Syntypes, sex?; Rio Grande do Sul, Brazil; NHMW, Wien

Ceratolepis barbatus Schedl, 1954:24. Syntypes ♂ ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien and Plaumann Collection (preoccupied by Eggers 1912:207)

Cnemonyx schedli Wood, 1972:244. Syntypes; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, and Plaumann Collection, unneeded replacement name

Diagnosis: Distinguished by the smooth, shining, coarsely punctured pronotum; by the slender, hairlike interstitial setae; and by the frontal vestiture.

Male: Length 1.8–2.1 mm, 1.9 times as long as wide; color brown. Frons feebly concave from epistoma to well above upper level of eyes; central three-fourths from upper level of eyes almost to epistoma densely pubescent, setae coarse, erect, slightly longer on lateral and dorsal margins; surface above eyes and laterally to epistoma finely, closely punctate (finely granulate above); epistomal margin narrowly subcarinate on median half; callus poorly formed, moderately large. Pronotum 0.94 times as long as wide; surface obscurely reticulate on anterior half, smooth, shining behind, punctures rather coarse, deep, close, most spaced by less than half diameter of a puncture; glabrous. Elytra 1.25 times as long as wide, 1.3 times as long as pronotum; bases as in *creber* Schedl; striae moderately impressed, punctures small, distinct; interstriae slightly convex, surface dull, each with a uniseriate row of rather coarse, acute crenulations from base to base of declivity, each two-thirds or more times as wide as an interstriae. Declivity occupying posterior half, convex, rather steep; striae deeper and interstriae narrower than on disc; crenulations narrower and slightly higher. Vestiture of uniseriate rows of fine, short, semirecumbent bristles, each equal in length to one-third to one-half distance between rows, spaced within a row by less than length of a bristle.

Female: Similar to male except frons convex almost to epistoma, subreticulate and punctured to epistoma, vestiture more evenly, sparsely distributed over a smaller area.

Distribution: Brazil: Rio Grande do Sul; Nova Teutonia, Santa Catarina, XII-1940, F. Plaumann.

Notes: The above treatment was based on 3 males and 2 females from Nova Teutonia that were compared by me directly to the male lectotype of *errans* (Blandford) and to the syntypes of *brasiliensis* Schedl and *barbatus*

Schedl. The species *errans* was named from specimens recovered in Paris from tobacco refuse that was thought to have originated in Mexico. Because all known specimens of this species are from Brazil, it is now obvious that the lectotype of *errans* came from Brazil, not Mexico.

Cnemonyx longicollis (Blandford)

Cnemonyx longicollis (Blandford), 1896:128 (*Loganius*). Holotype ♀; "Mexico" (actually Brazil) tobacco refuse intercepted at Paris; BMNH, London (References in Wood & Bright c1992:316)

Diagnosis: Superficially resembling *flavicornis* (Chapuis) in size, form, and sculpture, but probably remotely related; antennal club with only one obscure suture; frons at level of antennal insertion with an obscure, minute, transverse carina; anterior third of pronotum reticulate.

Female: Length 2.3 mm, 2.47 times as long as wide; color dark reddish brown. Frons somewhat flattened from epistoma to upper level of eyes; surface reticulate, punctures rather small, moderately close, shallow; vestiture hairlike, rather short, moderately abundant, uniformly distributed from epistoma to upper level of eyes; median one-sixth at level of antennal insertion with a small, rather weak transverse carina (much lower in height and smaller than in *flavicornis*). Antennal club with only one obscure suture. Pronotum 1.02 times as long as wide; surface reticulate on anterior third, somewhat etched on middle third, almost smooth near base; punctures small, oval, spaced by about one to three diameters of a puncture; vestiture of sparse, rather long, coarse setae in lateral areas of anterior third. Elytra 1.3 times as long as wide; basal margins with weak crenulations obscurely indicated, submarginal crenulations absent; striae not impressed, punctures small, moderately deep; interstriae about twice as wide as striae, smooth, somewhat shagreened, punctures about two-thirds as large as those of striae. Declivity convex, steep; striae moderately, narrowly impressed; interstriae rather narrowly convex, anterior margins of punctures weakly tuberculate, surface rather dull; costal margin at declivity subserrate. Vestiture of uniseriate rows of interstitial setae at least on declivity largely abraded on disc and sides, each about equal in length to half distance between rows, somewhat flattened, about six times as long as wide.

Distribution: Brazil: "Mexican tobacco refuse intercepted at Paris." All Blandford species bearing this label are now known to have come from Brazil. The exact locality is unknown.

Notes: The above treatment was based on the female holotype.

Cnemonyx acuminatus Schedl

Cnemonyx acuminatus Schedl, 1976:61. Holotype ♀; Encruzilhada, Bahia, Brazil; NHMW, Wien (References in Wood & Bright c1992:313)

Diagnosis: Distinguished by the very small size and slender body form; by the reddish brown body color; by

the near absence of submarginal interstitial crenulations behind the marginal row at the base of the elytra; and by the near absence of interstitial setae on the elytral disc.

Female: Length 1.5 mm, 2.8 times as long as wide; color rather light reddish brown. Frons rather deeply, abruptly concave on median half to distinctly below upper level of eyes; sides and above rather finely rugose-reticulate and glabrous; concave area rather densely filled by rather short, erect setae; antennae missing except for one rather short, stout scape; eye elongate-oval, entire, rather coarsely faceted. Pronotum 1.1 times as long as wide; sides subparallel on basal half, gradually converging toward rather broadly rounded anterior margin; surface almost smooth, shining on basal half, reticulate on anterior third; punctures rather small, oval, shallow, rather numerous; glabrous. Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; basal margins regularly, finely crenulate, submarginal crenulations very weak, apparently about two to four crenulations present on 2 and 3; striae not impressed, punctures small, shallow, distinctly impressed; interstriae slightly more than twice as wide as striae, mostly smooth, shining, punctures mostly shallow, obscure, some almost as large as those of striae, uniseriate. Declivity occupying almost posterior third of elytral length, convex, rather steep, somewhat narrowly rounded behind; striae shallowly impressed; interstriae reticulate or rugose-reticulate, 1–9 armed by several, uniseriate, small, pointed tubercles on or near declivity. Vestiture of uniseriate rows of sparse, interstitial setae on and near declivity, longest setae equal in length to about one-fourth distance between rows.

Distribution: Brazil: Bahia, Encruzilhada, XI-1972, 980 m, M. Alvarenga.

Notes: The above treatment was based on the female holotype.

Cnemonyx brevisetosus Schedl

Cnemonyx brevisetosus Schedl, 1939:407. Lectotype ♀; Isla Martin Garcia, Buenos Aires, Argentina; NHMW, Wien, present designation (References in Wood & Bright c1992:314)

Diagnosis: Distinguished from *insidiosus* (Schedl) by the smaller size; by the much larger, shallow punctures on the pronotum; by the narrower frontal impression with setae longer and more numerous.

Male: Similar to female except frontal impression not as deep, vestiture slightly shorter, less abundant.

Female: Length 1.0–1.1 times as long as wide; color almost black. Frons convex above and laterally, central third moderately concave, surface somewhat rugose-reticulate at sides and above, epistomal area procurved and smooth, shining, concave area very finely punctured; vestiture of fine hair of moderate length and abundance. Pronotum 0.90 times as long as wide; widest at base, slides weakly arcuate and converging toward rather broadly rounded anterior margin; surface strongly reticulate, punctures moderately numerous, rather large,

most about equal in size to a stria puncture (on disc); vestiture rather sparse, of rather stout hair. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; crenulations on basal row rather coarse, about eight submarginal crenulations on 2 and 3; striae not impressed, punctures small, distinct; interstriae three times as wide as striae, each with a uniseriate row of subvulcanate, setiferous tubercles to base. Declivity confined to posterior third of elytral length, convex, steep; sculpture about as on disc, except striae weakly impressed. Vestiture of minute stria hair on declivity, and uniseriate rows of erect interstitial setae regularly placed from base to apex, each seta flattened, about eight times as long as wide, equal in length to distance between rows, slightly more closely spaced within a row.

Distribution: Argentina: Isla Martin Garcia, Buenos Aires, IV-1938, M.J. Viana.

Notes: This species was based on a syntypic series. Subsequently, Schedl (1979:47) labeled and cited a female from his series as the "holotype." Because subsequent designations of primary types must be lectotypes, I here designate Schedl's "holotype" as the lectotype of *Cnemonyx brevisetosus* Schedl.

Cnemonyx insidiosus (Schedl)

Cnemonyx insidiosus (Schedl), 1939:171 (*Loganius*). Syntypes, sex?; Isla Martin Garcia, Buenos Aires, Argentina; NHMW, Wien, and Viana Collection (References in Wood & Bright c1992:316)

Diagnosis: Distinguished from *galeritus* Eichhoff by the stouter, almost scalelike interstitial setae; by the steeper elytral declivity; and by the less strongly impressed declivital striae and larger interstitial tubercles.

Female: Length 1.3 mm, 2.2 times as long as wide; color black, setae white. Frons shallowly impressed on central half, ending below upper level of eyes; surface shining, smooth in central area, finely, not closely punctured in lateral areas, finely rugose above upper level of eyes; fine, sparse, moderately long hair in impressed area, except absent on median line. Pronotum 0.94 times as long as wide; surface strongly reticulate to base, punctures moderately coarse, shallow, spaced by 1–3 diameters of a puncture; vestiture restricted to anterior third, sparse, flattened, moderately long. Elytra 1.45 times as long as wide, 1.53 times as long as pronotum; basal margins armed by a row of coarse crenulations, bases of interstriae 2–5 with at least eight coarse, submarginal crenulations; striae not impressed, punctures small, shallow, distinct; interstriae about twice as wide as striae, smooth, shining, each with a uniseriate row of small tubercles. Declivity confined to posterior one-third of elytral length, convex, steep; sculpture about as on disc except interstitial tubercles very slightly larger. Vestiture of interstitial rows of semierect, flattened setae, each about eight times as long as wide, length slightly shorter than distance between rows, slightly closer within a row; costal margin serrate near suture.

Distribution: Argentina to Bolivia.

Argentina: Isla San Martin Garcia in Buenos Aires. Bolivia: Montenguideo (Monteagudo?), Rio Azero, IX-1920, G.L. Harrington.

Notes: The above treatment was based on 1 specimen that I compared to the "allotype," presumably a female.

Cnemonyx galeritus Eichhoff

Cnemonyx galeritus Eichhoff, 1868:150. Holotype, sex?; Chili; NHMW, Wien (References in Wood & Bright c1992:315–316)
Minulus barbatus Eggers, 1912:207. Holotype ♀?; Creta (intercepted?); Museo Zoologico, Universitatis Havniae (now UZMC, Copenhagen) (References in Wood & Bright c1992:314). *New synonymy*

Diagnosis: Distinguished from *insidiosus* (Schedl) by the hairlike interstitial setae; by the more gradual elytral declivity; and by the more strongly impressed declivital striae, with the interstitial tubercles smaller.

Male: Length 1.5–1.6 mm, 2.4 times as long as wide; color dark brown to black.

Frons about as in female *insidiosus* except vestiture from epistoma to upper level of eyes densely pubescent, setae fine, hairlike, slightly longer. Pronotum 0.95 times as long as wide; smooth, shining on basal fourth, apparently at least partly reticulate on anterior half (obscured by frass), punctures small, close, shallow; vestiture of fine, moderately long, rather abundant hair. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; basal margin, striae, and discal interstriae about as in *insidiosus*. Declivity occupying slightly more than posterior third of elytral length, not as steep as in *insidiosus*; striae more strongly impressed, interstitial tubercles slightly smaller. Vestiture of uniseriate interstitial rows of erect, almost hairlike bristles.

Female: Similar to male except frons more distinctly impressed, setae less abundant.

Distribution: Chile: "Chili"; Cerro Robles, P. Santiago, 7-IV-1968, 6300 ft.; Cordillera, Rio Clarillo, 28-IX-1989, C. Ganzales; Santiago, El Volcan, 9-I-1990, *Colliguaja intergerrima*, Euphorbiaceae, E. Fuentes; Santiago, Pudahuel, XI-1953, L. Pena.

Notes: The above treatment was based on my homotype that I compared directly to the holotype of *galeritus* (Eichhoff), on 6 specimens from Chile, and on the holotype of *Minulus barbatus* Eggers that was apparently intercepted on the Island of Crete.

Species Not Seen

Cnemonyx parvus (Nunberg)

Cnemonyx parvus (Nunberg), 1933:13 (*Ceratolepis*). Holotype, sex?; St. Laurent du Maroni, French Guyane; MNHN, Paris (References in Wood & Bright c1992:317). Not found

GENUS *CAMPTOCERUS* LATREILLE

Camptocerus Latreille, 1829:91. Type-species: *Hylesinus aeneipennis* Fabricius (References in Wood & Bright c1992:318–321)

Diagnosis: Flat elongate scutellum even (flush) with basal surface of elytra (not depressed); ventral profile of abdomen ascending gradually; suture 1 on antennal club marked internally by a partial septum; meso- and metathoracic tibiae acutely margined on apical anterior edge, without supplemental denticles.

Description: Length 2.7–8.5 mm, 1.6–2.3 times as long as wide; color dark brown to black, except *aeneipennis* (Fabricius) often with a bright, metallic sheen, males of some species ornamented by variegated patterns formed by erect scales. Frons of male deeply, broadly concave from epistoma to vertex, often ornamented by setae, convex in female; antennal scape elongate, funicle 7-segmented, club rather strongly flattened, somewhat asymmetrical in outline, suture 1 indicated internally by a partial septum, surface densely covered by fine pubescence. Pronotum large, broad, unarmed; lateral margins acutely marked by a fine costa. Scutellum flat, flush with elytral surface. Elytral bases marked by a fine, raised, continuous line, not emarginate toward scutellum; striae not impressed, punctures fine, sculpture simple, except in *quadridens* Blackman; abdomen ascending rather strongly to meet apex of elytra. Vestiture varying from absent to abundant hair or scales.

Distribution: Tropical America. Wood & Bright (c1992: 318–320) list 19 species, 17 of which occur in South America.

Biology: All species are xylomycetophagous. While some infest large logs, others breed in tiny twigs. Several species bore an entrance tunnel to the cambium area where a transverse, biramous tunnel is formed (without turning or egg niches). Near the center of this transverse gallery, but never directly below the entrance tunnel, a new radial tunnel is excavated that penetrates deeply into the wood. This deep, inner tunnel usually branches into 2–4 arms along which eggs are deposited in niches. The larvae then expand these niches into short, broad, larval cradles where pupation occurs. The walls of the tunnels and cradles are stained black by mycelial growth of the symbiotic fungi. Apparently a few species bore directly into the deep wood and eliminate the transverse tunnel in the cambium area. In smaller species, such as *infedelis* Wood, the gallery system is radically modified to accommodate the confining space of small stems. While most of the recorded hosts of species in this genus are species of *Protium*, it should not be implied that they are restricted to hosts of that genus.

Key to the Species of *Camptocerus*

- 1. Setae on metepisternum bifid or trifid; male frons with excavated area (usually deeper) extending to epistoma; area between antennal insertions of male either unarmed, armed by a large median tubercle, or armed by a short, transverse carina occupying less than median third (see also *latipilis*) 2
- Setae on metepisternum palmately divided into more than four filaments; male frons armed on lower fourth by a transverse carina extending from margin to margin (absent in *tectus*; feebly developed in *occidentalis* and *niger*) 8
- 2(1). Interstriae with punctures more numerous, usually confused, either glabrous or with setae confused; striae punctures smaller; lower male frons either unarmed or armed by a large, median tubercle; scape only moderately expanded on apical half, setae distributed over apical two-thirds 3
- Interstriae with punctures less numerous, usually uniseriate, setae uniseriate; striae punctures larger; male frons with a short transverse carina; apical third of male scape abruptly, rather strongly expanded, setae confined to expanded area; surfaces of pronotum and elytra smooth, shining (females unknown) 7
- 3(2). Male frons unarmed 4
- Male frons armed by a large median tubercle at level of antennal insertion 6
- 4(3). Pronotum and elytra glabrous, smooth, shining, with minute micropunctures (80X), usually black, with a metallic sheen; pronotum often rufescent; Costa Rica to Argentina; *Protium*; 3.5–6.0 mm *aeneipennis* (Fabricius)
- Pronotum (part or all) and elytra clothed by long, recumbent, pale setae borne by both striae and interstitial punctures; color almost black (rather dull) or with a black and reddish brown pattern ... 5
- 5(4). Body more slender, 2.1 times as long as wide; pronotum 0.91 times as long as wide, profile more evenly rounded from base to anterior margin, punctures slightly larger, with very fine, moderately

SCOLYTINI

- long hair uniformly distributed from base to anterior margin (sometimes abraded); eyes more narrowly separated above by 2.5 times width of an eye; presumably NE South America and Guiana; 4.2 mm *cinctus* Chapuis
- Body stouter, 1.8 times as long as wide; pronotum 0.77 times as long as wide, dorsal profile much more strongly arched on anterior one-fifth, punctures finer, densely pubescent on anterior one-fifth, almost glabrous behind; eyes separated above by 3.5 times width of an eye; Guiana and French Guyane to Brazil (Sao Paulo); 3.2–4.3 mm *suturalis* (Fabricius)
- 6(3). Anterior margin of pronotum above eye more evenly rounded in both sexes, never transversely sulcate; striae not impressed, punctures smaller, deeper; interstitial punctures on disc mostly uniseriate, on lower declivity smaller, deeper; most of setae on upper half of male frontal excavation with their apex flattened (consistent?); French Guyane to Brazil; 2.5–3.8 mm *aterrimus* Eggers
- Area above anterior margin of pronotum transversely impressed (female) to sulcate (male) at least in lateral area; striae not impressed, punctures slightly larger, more shallow; interstitial punctures on disc mostly confused, on lower declivity slightly larger, not as deep; setae in male frontal excavation with their apices pointed, only a few on lateral margins flattened; Colombia to Bolivia and Brazil; 4.5–5.5 mm *angustior* Eggers
- 7(2). Male declivital striae distinctly impressed, punctures larger, deeper, basal area unarmed; male declivital interstitial setae uniseriate, stout, shorter than distance between rows; Trinidad to Brazil; 3.0–3.2 mm *costatus* Chapuis
- Male declivital striae not impressed, punctures smaller, not as deep; male discal interstriae 1 and 2 each ending in a large spine at a point about one-third elytra length from base, bases of these spines join to form a fold overhanging declivity; male interstitial setae on declivity uniseriate, slender, much longer than distance between rows; Panama; 3.1 mm *quadridens* Blackman
- 8(1). Interstitial setae more abundant, confused; male frons less abruptly excavated, its surface sculpture with lateral areas closely punctured, median line and lateral margins impunctate, punctured areas ornamented by conspicuous, long, yellow setae 9
- Interstitial setae uniseriate or absent; male frons more abruptly impressed, surface sculpture uniform, punctures not clearly evident, setae sparse inconspicuous 14
- 9(8). Male frons with a transverse carina below level of antennal insertion feeble to obsolete 10
- Male frons with conspicuous, moderately to strongly developed transverse carina, if carina weak then a median epistomal tubercle present 11
- 10(9). Male frons with carina entirely obsolete, central area at and below level of antennal insertions very finely, densely rugose-reticulate; Colombia to Peru and Brazil (Pernambuco); 2.8–3.2 mm *tectus* Eggers
- Male frons with carina weak to moderate, central area below level of antennal insertion with several small punctures; Guiana and French Guyane to Brazil (Mato Grosso; *Protium*; 2.6–3.5 mm *niger* (Fabricius)
- 11(9). Male frontal carina below level of antennal insertion, rather weak, procurved 12
- Male frontal carina above level of antennal insertion, strong, almost straight 13
- 12(11). Male frontal carina subacute, without a median tubercle below carina; Brazil (Bahia to Pernambuco); 3.0–3.5 mm *orientalis* Eggers
- Male frontal carina with its summit obtuse, a conspicuous median tubercle immediately below carina; Nicaragua to Guiana and Venezuela; 3.3–4.0 mm *auricomus* Blandford

- 13(11). Male frons very weakly concave on small area equal to about one-third diameter of frons; male frontal carina highest on its median third, weakly developed on lateral thirds; Venezuela; *Protium*; 3.0–3.4 mm **rectus** Wood
- Male frons extensively concave from eye to eye from vertex to carina; male frontal carina subacute from one lateral margin to other, highest at lateral ends, its crest running a moderately concave course; Bolivia to Peru; 3.6–4.1 mm **occidentalis** Eggers
- 14(8). Body stout, 1.6 times as long as wide; male carina immediately above epistoma, short, about one-fifth as wide as lower area of frons; female interstriae with low, transverse crenulations from base to near apex; Brazil (Para); 2.3–2.7 mm **latipilis** Schedl
- Body more slender, 2.0 or more times as long as wide; male carina at level slightly above level of antennal insertions 15
- 15(14). Elytra appearing subglabrous, minute hairlike interstitial setae present 16
- Interstriae with longer, scalelike setae at least on declivity 17
- 16(15). Male frontal carina rather strongly developed, of uniform height; Brazil (Santa Catarina); 2.5–3.2 mm **inoblitus** (Schedl)
- Male frontal carina not of uniform height, highest on median third, less clearly impressed below; Brazil (Santa Catarina); 2.1 mm **morio** (Schedl)
- 17(15). Pronotum feebly reticulate on discal area, punctures small, spaced by 2–6 diameters of a puncture; striae not impressed, punctures small, shallow, spaced within a row by two or more diameters of a puncture; interstriae smooth, shining, punctures very small, shallow, at least as widely spaced as those of striae (about four to eight diameters of an interstitial puncture); setae confined to declivity, each about 6 to 8 times as long as wide; Costa Rica; ex 1 cm tree seedling; 2.7–3.2 mm **infedelis** Wood
- Pronotum strongly reticulate throughout, punctures larger, spaced by 1 to 3 diameters of a puncture; striae feebly impressed, punctures deeper, spaced within a row by one diameter of a puncture; interstriae almost smooth, punctures smaller than those of striae and as closely spaced (about three times diameter of an interstitial puncture) 18
- 18(17). Pronotal punctures larger, spaced by one-half diameter of a puncture; interstitial scales each about four to six times as long as wide; Bolivia to Brazil; 1.8–2.5 mm **opacicollis** (Eggers)
- Pronotal punctures smaller, spaced by more than 1 to 2 diameters of a puncture; interstitial scales more slender, each six to eight times as long as wide 19
- 19(18). Pronotum rather strongly reticulate to or near base; interstitial punctures small, their anterior margins feebly if at all elevated; Brazil (Amazonas, Goyas); 2.7–3.3 mm **major** (Eggers)
- Posterior two-thirds of pronotum smooth, brightly shining, punctures minute; interstitial punctures as large as those of striae, their anterior margin weakly to moderately elevated; Brazil (Ceara); 3.4 mm **annectens** Wood

Camptocerus aeneipennis (Fabricius)
Plate XXIX

Camptocerus aeneipennis (Fabricius), 1801:392 (*Hylesinus*). Lectotype ♂; labeled [Rio] Essequibo [Guiana], published as *America Meridionali*; UZMC, Copenhagen, designated by Wood 1982:412 (Synonymy and references in Wood & Bright c1992:318–319)
Hylesinus gibbus Fabricius, 1801:392. Holotype ♀; labeled [Rio] Essequibo [Guiana], published as *America meridionali*; UZMC, Copenhagen

Diagnosis: Distinguished by the large size; by the metallic sheen; by the glabrous elytra, with fine, confused punctures; and by the unarmed lower male frons.

Male: Length 3.5–6.0 mm, 1.8 times as long as wide; mature color black, pronotum somewhat reddish brown when not fully mature, frequently with a brilliant metallic sheen. Frons deeply, broadly concave eye to eye from vertex to level of antennal insertion; lateral margins

subacute below; surface reticulate, transcending to smooth below, very closely, moderately punctured in concave area, almost smooth (a few minute punctures) in sulcus; vestiture of abundant, moderately long hair in concave area, sparse, minute hair in sulcus; funicle segments 2–7 ornamented by a brush of long hair. Pronotum 0.77 times as long as wide, widest at base; surface smooth, shining, some reticulation near anterior margin, wrinkling often on basal fourth; punctures minute, not close, slightly larger near anterior margin; glabrous. Elytra 1.1 times as long as wide, 1.5 times as long as pronotum; widest at base; striae not impressed, punctures very small, spaced within a row by one to three times diameter of a puncture; interstriae four to five times as wide as striae, smooth, shining, punctures minute, moderately abundant, confused. Declivity convex, rather steep; sculpture about as on disc, except some interstriae with punctures almost uniseriate. Glabrous.

Female: Similar to male except frons convex, reticulate, shallowly, closely punctured, with a median callus, vestiture sparse, very short; funicle brush absent.

Distribution: Costa Rica to Argentina.

Argentina: Cited in Wood & Bright c1992:318.

Bolivia: Chuma, La Paz, XII-1935, Y. Mexia.

Brazil: Benevides, Para, II-1895, Gounelle, Pery-Pery, Pernambuco, 5-VI-1982, Gounelle; Monte Alegre, Para, perforating leguminous leaves, G. Vogt; Salobro, Bahia, 7-VI-1885, E. Gounelle; Recife [Pernambuco], 6-V-1892; Sao Paulo, Santa Catarina; Presidente Figueireido, Amazonas, Forest, P. Grossi.

Colombia: Bogota; 8 km S Colonia, Valle de Cauca, 9-VII-1970, 30 m, No. 628 in *Icica altissima*, No. 631 in *Protium nervosum*, SLW.

Venezuela: 9 km S Barancas, Barinas, 2-XII-1969, 150 m, No. 170, *Protium*, SLW; 40 km E Canton, Barinas, 8-III-1970, 70 m, No. 398, *Protium tenuifolium*, *Protium*, SLW; 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 262, *Protium*, SLW.

Biology: Felled and broken trees were attacked in stems 8 to more than 30 cm in diameter. An entrance tunnel was excavated in the bark to the surface of the wood where a transverse, biramous gallery was formed, each arm about 3 cm or more in length. From this gallery, but not directly below the entrance tunnel, a radial tunnel was bored an additional 3–6 cm into the wood. This inner tunnel usually divided into 2–4 branches along which egg niches were formed at about 3-mm intervals. Two rows of egg niches were formed above and 1 below in the egg gallery. The larvae enlarged their egg niche into a cradle as they grew and later used these cradles as pupation chambers. The galleries were stained black by the ambrosia fungus mycelium that apparently was used as the principal source of food. In Venezuela, where this species was present in near epidemic numbers, the transverse tunnel in the cambium area was eliminated; the entrance tunnel extended directly into the deep brood area. In a number of areas this species was observed

to cut small, circular holes in thick leaves (each hole about the diameter of a gallery chamber) then a beetle crawled into the hole and rested or merely passed through the perforation. Although this habit could relate to maturation feeding, its significance has not been investigated.

Notes: The above treatment was based on the lectotype of *Hylesinus aeneipennis* Fabricius, the holotype of *Hylesinus gibbus* Fabricius, 25 specimens from Costa Rica, 2 from Bolivia, 31 from Brazil, 8 from Colombia, and 57 from Venezuela.

Camptocerus cinctus Chapuis, n. status

Camptocerus cinctus Chapuis, 1869:51. Holotype ♀; Amerique meridionale; IRSNB, Brussels (References in Wood & Bright c1992:320)

Camptocerus charpentierae Schedl, 1970:582. Holotype ♂; Massikiri-Haut Oyapock, French Guyane; NHMW, Wien (References in Wood & Bright c1992:319). *New synonymy*

Diagnosis: Distinguished from *suturalis* (Fabricius) by the more evenly arched dorsal profile of the pronotum; by the uniform distribution of slender setae from the anterior margin to the base of the pronotum; by the more slender body; and by other characters described below.

Female: Length 4.2 mm, 2.1 times as long as wide, mature color probably very dark brown, type rather pale reddish brown with parts of elytra dark brown (not fully colored?). Frons broadly convex on upper two-thirds, shallowly, transversely impressed below; eyes separated above by 2.5 times width of an eye (3.5 times in *suturalis*); surface reticulate, punctures close, rather small, moderately deep above, almost smooth and more finely punctured on lower one-third; vestiture rather short, moderately coarse, of recumbent setae of moderate abundance; funicular brush not present. Pronotum 0.91 times as long as wide; dorsal profile evenly arched (not conspicuously more abrupt on anterior one-fifth), surface smooth, shining, punctures distinctly deeper, slightly larger than in *suturalis*, vestiture uniformly distributed from anterior margin to base, setae finer, recumbent. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures small, shallow, distinct from base to apex; interstriae subreticulate, densely covered by micropunctures, punctures about half as large as those of striae, confused from base at least to base of declivity, somewhat uniseriate on declivity. Declivity broadly convex, moderately steep, sculpture essentially as on disc. Vestiture of slender, recumbent setae, rather short on striae, distinctly longer on interstriae; setae on ventral surfaces of metathorax and abdominal segment 1 bifid (on *suturalis* as least half divided into 3–5 filaments).

Distribution: Brazil, French Guyane, and “South America.”

South America: “Am. meri., Dejean.”

Brazil: 69 km N Manaus, 7-XII-1979, G. Stevens.

French Guyane: Massikiri-Haut Oyapock.

Notes: The above treatment was based on the female holotype of *cinctus* Chapuis. Chapuis Collection specimens of other species similarly labeled came from northeastern South America, possibly Guiana. The male holotype of *charpentieri* Schedl was examined and compared to my female from Manaus. The color, color pattern, slender body and narrow spacing between the eyes match exactly the female holotype of *cinctus*, except that the Manaus specimen has lost almost all of the setae from the pronotum and elytra. Because the few setae remaining on the lateral areas of the pronotum and on the lateral areas and declivity of the Manaus female, they are considered to be identical to those in similar positions on the holotype of *cinctus*, the 2 names are considered synonymous. The name *cinctus* has been previously incorrectly identified by all authors except Chapuis.

Camptocerus suturalis (Fabricius)

Plate XXXIII

Camptocerus suturalis (Fabricius), 1801:393 (*Hylesinus*). 4 syntypes, sex?; labeled [Rio] Essequibo [Guiana], published as *America meridionale*; UZMC, Copenhagen (Synonymy and references in Wood & Bright c1992:320)

Hylesinus fasciatus Fabricius, 1801:392. Syntypes 1 ♂, 1 ♀; Esequibo [River], Guiana; UZMC, Copenhagen

Camptocerus hirtipennis Schedl, 1973:165. Holotype ♂; Tefe (=Ega), Brazil; MZUSP, Sao Paulo

Diagnosis: Distinguished by the large size, with confused interstitial punctures; by the long, recumbent, pale setae borne by both striae and interstitial punctures; and by the unarmed lower male frons.

Male: Length 3.2–4.3 mm, 1.8 times as long as wide; color very dark reddish brown, almost black, vestiture pale. Frons as in *aeneipennis* (Fabricius) except lower area reticulate almost to epistoma, brush on funicle much smaller. Pronotum 0.77 times as long as wide; as in *aeneipennis* except surface reticulate, punctures smaller, anterior one-fifth rather densely covered by coarse, recumbent hair of moderate length. Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; resembling *aeneipennis* except surface reticulate, striae punctures minute, almost indistinguishable from those of interstriae. Vestiture of white or yellowish, rather coarse, recumbent, confused, hairlike setae of moderate length and abundance covering entire surface.

Female: Similar to male except frons convex, a weak impression on median half from vertex to epistoma, surface rugose-reticulate, vestiture sparse; brush on funicle absent; posterior half of pronotum smooth, shining.

Distribution: French Guyane and Guiana to Brazil (Sao Paulo).

Brazil: Tefe (=Ega); 69 km N Manaus, 7-XII-1979, G. Stevens.

Guiana: [Rio] Essequibo (type).

Notes: The above treatment was based on the syntypes of *Hylesinus suturalis* Fabricius and *H. fasciatus* Fabricius, and on 14 other specimens from Brazil.

Camptocerus aterrimus Eggers

Plate XXX

Camptocerus aterrimus Eggers, 1933:12. Holotype ♀; Passoura, French Guayane; MNHN, Paris (References in Wood & Bright c1992:318)

Diagnosis: Distinguished from *angustior* Eggers by the smaller size; by the median epistomal tubercle on the male; by the mostly uniseriate interstitial punctures on the elytral disc; and by the more evenly convex area behind the anterior margin in the lateral area of the pronotum.

Male: Length 2.5–2.8 mm, 1.9 times as long as wide; color black, glabrous. Frons concavely impressed about as in *aeneipennis* (Fabricius), except 2–3 setae on lateral margin near eye moderately spatulate; epistoma armed by a strong, conical, median tubercle; funicle segments 2–7 with a large brush of dark hair. Pronotum 0.84 times as long as wide; surface weakly reticulate on anterior half, shining behind, median half of posterior half conspicuously, transversely wrinkled, punctures rather small, moderately close, distinctly impressed; anterior area from anterior end of lateral costa shallowly, often concavely impressed (immediately above anterior margin) less than half distance to median line; glabrous. Elytra 1.1 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures small, distinctly impressed, surface smooth, with numerous minute micropunctures; interstriae five or more times as wide as striae, punctures about half as wide as those of striae, mostly uniseriate, those on 1, 2, and 4 moderately confused at least on basal half of disc. Declivity broadly convex, moderately steep; striae and interstitial punctures slightly smaller, deeper than on disc. Glabrous.

Female: Similar to male except frons convex, surface reticulate, punctures moderately coarse, rather deep, median tubercle on epistoma present, comparatively smaller than in male; vestiture of sparse, short, coarse hair; pronotum reticulate on anterior fourth, wrinkled area not present (smooth, shining); micropunctures on elytra much smaller.

Distribution: French Guyane to Brazil.

Brazil: Amazonenstromgebiet (syntype); 69 km N Manaus, 7-XII-1979, G. Stevens; Corcovado N.P., near Manaus, 26-XI-1979, G. Stevens; Mato Grosso 12°31'S, 51°46'W, 12-XI-1968, 12°50'S, 51°47'W, RS/RGS Exp.

French Guyane: Passoura.

Notes: The above treatment was based on 29 specimens from Brazil, 2 females of which I compared directly to the female holotype.

Camptocerus angustior Eggers

Plate XXX

Camptocerus angustior Eggers, 1928:91. Lectotype ♂; Bolivia (Yungas, 1000 m); USNM, Washington, designated by Anderson & Anderson 1971:4 (References in Wood & Bright c1992:318)

Diagnosis: Distinguished from *aterrimus* Eggers by the larger size; by the more strongly confused interstitial

punctures on the disc; and by the distinct impression (female) or transverse sulcus (male) immediately above the anterior margin of the pronotum at least in the lateral areas.

Male: Length 4.5–5.5 mm, 1.83 times as long as wide; color black, glabrous. Frons as in *aterrimus* except spatulate setae on lateral margin near eye apparently wider, more numerous. Pronotum about as in *aterrimus* except sulcus extending from anterior end of lateral costa (immediately above anterior margin) much stronger, more conspicuous, usually attaining median line (continuous with opposite side). Elytra about as in *aterrimus*, striae punctures slightly larger, not as deep, interstitial punctures on disc more strongly confused to upper declivity.

Female: As in female *aterrimus* except pronotum smooth, shining except near anterior margin; micropunctures on elytral disc obscure at 80X, almost obsolete; sulcus near anterior margin of pronotum much less strongly impressed than in male.

Distribution: Colombia to Bolivia and Brazil.

Bolivia: Yungas, 1000 m.

Brazil: 68 km N Manaus, Amazonas, 7-XII-1977, G. Stevens.

Colombia: Cited in Wood & Bright c1992:318.

Peru: 15 mi. NE Tingo Maria, 11-XI-1954, 700 m, E.I. Schlinger, E.S. Ross.

Notes: The above treatment was based on the male lectotype, 1 other male, 1 female from Brazil, and 1 female from Peru.

Camptocerus costatus Chapuis

Plate XXXI

Camptocerus costatus Chapuis, 1869:51. Holotype ♂; Brazil, taken by Dejean; IRSNB, Brussels (References in Wood & Bright c1992:319)

Camptocerus seriatus Eggers, 1933:12. Holotype ♀; Les roches de Konourou, French Guyane; MNHN, Paris (References in Wood & Bright c1992:320). *New synonymy*

Diagnosis: Male distinguished by presence of a short transverse carina just below middle of frontal concavity; by the uniseriate rows of erect interstitial bristles; by the declivity occupying the posterior four-fifths of the elytra length; and by the strongly elevated, narrowly convex declivital interstriae 8 that continues to the suture.

Male: Length 3.0–3.2 mm, 1.9 times as long as wide; color dark reddish brown. Frons with a short, transverse carina (on median one-sixth) distinctly above level of antennal insertion, broadly, moderately sulcate to epistoma below carina, deeply, broadly concave above carina to well above upper level of eyes, surface reticulate and closely, rather finely punctured above carina, smooth and sparsely, finely punctured below; vestiture of fine erect, abundant, rather long hair above, much shorter and sparse below carina; funicle segments 2–7 bearing a brush of long, dark hair. Pronotum 0.83 times as long as wide; surface reticulate, weakly near base, moderately on anterior half, punctures small, shallow, obscure, rather close; glabrous. Elytra 1.1 times as long as wide,

1.3 times as long as pronotum; declivity occupying posterior four-fifths, basal one-fifth with striae not represented, punctures very small, obscure, interstriae subreticulate (based on micropunctures), rather closely covered by broad, low crenulations. Declivity (posterior four-fifths) moderately impressed to apex; interstriae about twice as wide as striae, distinctly convex, each with a uniseriate row of crenulations (each crenulation more than half as wide as an interstriae near base, gradually decreasing in width to small tubercles on posterior one-fifth to obsolete at apex; interstriae 8 broadly, rather strongly elevated near middle of elytra, crest becoming narrowly costate on posterior one-fifth to suture. Vestiture confined to declivity, consisting of uniseriate rows of erect, stout bristles, each bristle slightly shorter than distance between rows, spaced within a row by slightly less than length of a bristle (each bristle slightly flattened, about 10 times as long as wide).

Female: Length 3.4 mm; similar to male except frons convex, rather finely punctured; antennal funicle and scape without long setae; declivity more strongly, evenly convex, interstriae 9 not elevated.

Distribution: Brazil to Trinidad Island.

Brazil: “Bresil, Dejean” (type).

French Guyane: Les roches de Kourou.

Trinidad: Morne Bleu, 21-VIII-1969, H. & A. Howden.

Notes: The above treatment was based on the male holotype of *Camptocerus costatus* and on my male that was compared to this holotype, and on the female holotype of *C. seriatus* Eggers.

Camptocerus quadridens Blackman

Plate XXXIII

Camptocerus quadridens Blackman, 1943:379. Holotype ♂; Cooper’s near source of Rio Aejeta, Canal Zone, Panama; USNM, Washington (References in Wood & Bright c1992:320)

Diagnosis: Male distinguished by the short transverse carina at the level of antennal insertion; by the impressed declivity, with very slender, long, interstitial setae; and by the very coarse spine and lateral lobe at the base of the declivity.

Male: Length 3.1–3.4 mm, 1.9 times as long as wide; color rather dark reddish brown. Frons with a strong transverse carina on median one-fifth at level of antennal insertion, broadly, strongly concave above carina to well above upper level of eyes, continued below carina as a broad sulcus to epistoma; surface of concave area reticulate, rather finely, closely, deeply punctured, more nearly smooth below carina and sparsely, more finely punctured; vestiture of fine, erect, abundant, long hair; funicle segments 2–7 with a moderate brush of long hair. Pronotum 0.87 times as long as wide; surface smooth, shining except reticulate on anterior third; punctures small, deep, moderately close; almost glabrous. Elytra 1.1 times as long as wide, 1.3 times as long as pronotum; declivity occupying more than posterior half, separated from disc by an abrupt impression and overhanging

spine and lobe; disc smooth, shining, striae punctures minute to obsolete, interstriae punctures not evident; posterior margin of disc on interstriae 1 formed into a large, pointed spine directed caudad, its base continued laterad to form a large, procurved, rounded lobe above interstriae 2 and 3, crest declining laterad and becoming crest of slightly elevated interstriae 8. Declivity broadly convex, moderately steep; striae weakly impressed, punctures small, distinct; interstriae about three times as wide as striae, surface smooth, shining, each with a sparse row of obtusely pointed tubercles; crest of 8 continued as ventrolateral margin to suture. Vestiture restricted to declivity, consisting of uniseriate rows of setae, those on basal half of 1–3 very long, slender, others rather stout, each about as long as distance between rows.

Distribution: Panama: Cooper's near source of Rio Aejeta, Canal Zone, 19-VIII-1923, No. 2198, from felled tree, J. Zetek; Cerro Jefe, 19°12'N, 79°21'W, 24-II-1973, Stockwell.

Notes: The male holotype and 2 other males were examined. Zetek took *aneipennis* Fabricius at the same locality and date that he took this species; this suggests the possibility that the host might have been a *Protium* sp.

Camptocerus tectus Eggers

Camptocerus tectus Eggers, 1943:244. Holotype ♂; Sarra da Bermada, Pernambuco, Brazil; DEI, Muncheberg (References in Wood & Bright c1992:320)

Diagnosis: Male distinguished from male *orientalis* Eggers by absence of a transverse carina on the lower frons and by other minute differences in sculpture on the lower frons (see below).

Male: Length 3.0–3.2 mm, 1.8 times as long as wide; color dark brown, setae all pale. Frons resembling *orientalis* except transverse carina absent, frons less strongly concave (especially in lower area), area from level of antennal insertion to epistoma (tips of long yellow setae shorter than *orientalis*) less strongly impressed, minutely rugose-reticulate, median half without punctures (finely, rather closely punctured and not rugose-reticulate in *orientalis*, with no indication of a transverse carina; yellow setae in concave area ending well above level of antennal insertion). Pronotum and elytra about as in *orientalis* except interstitial setae appearing larger, broader, closer, on disc each about four times as long as wide, on lower declivity more slender, each about six to eight times as long as wide.

Female: Differences in females not clearly evident in material examined.

Distribution: Colombia to Peru and Brazil.

Brazil: Sarra de Berada, Pernambuco, 5-VI-1894, Duhant.

Colombia: Carton de Colombia forest 8 km S Colonia, Valle de Cauca, 9-VII-1970, 30 m, *Protium nervosum*, SLW.

Peru: Varias-Aguaytia, Tingo Maria, 6-7-IX-1944, E.J. Hambleton.

Notes: The above treatment was based on the male holotype and on 2 male paratypes, all bearing the type data, from Brazil, all in the DEI, Eberswalde; on 1 from Peru; and on 9 from Colombia. In general, *tectus* occurs at higher elevations toward the west and *niger* (Fabricius) in the lowlands east of the Andes Mountains. It is suspected that the two will fully intergrade when more material is available for study in intervening areas.

Camptocerus niger (Fabricius)

Plate XXXII

Camptocerus niger (Fabricius), 1801:393 (*Hylesinus*). Lectotype ♂; type labeled [Rio] Essequibo [Guiana], published as America meridionali; UZMC, Copenhagen, designated by Wood 1982:415 (Synonymy and references in Wood & Bright c1992:419)

Camptocerus squammiger Chapuis, 1869:51. Syntypes 1 ♂, 1 ♀; Cayenne, French Guyane; IRSNB, Brussels

Camptocerus striatulus Hagedorn, 1904:547. Syntypes, sex?; French Guyana; MNHN, Paris

Diagnosis: Male frons without a carina and few or no micropunctures below level of antennal insertion, median line and lateral areas without punctures or setae; interstitial setae abundant, confused.

Male: Length 2.6–3.5 mm, 1.8 times as long as wide; color very dark brown, setae pale to brown in an indefinite pattern. Frons rather strongly concave from eye to eye, from level of antennal insertion to vertex; surface subreticulate, closely, rather finely punctured in concave area, median line and lateral margins without setae, setae fine, long above, shorter below; area between antennal bases minutely rugose-reticulate, impunctate, transverse carina on median half of epistoma obscure, poorly formed; antennal scape with a conspicuous brush. Pronotum 0.86 times as long as wide; surface smooth, shining, obscurely reticulate near anterior margin, punctures small, deep, very close, spaced by less than diameter of a puncture; vestiture sparse, fine, short. Elytra 1.05 times as long as wide, 1.2 times as long as pronotum; striae weakly impressed, punctures small, impressed; interstriae about three times as wide as striae, surface almost smooth, shining, punctures two-thirds as large as those of striae, moderately impressed, strongly confused. Declivity occupying slightly more than posterior half of elytra length, broadly convex, moderately steep; striae more strongly impressed than on disc, interstriae narrower and more strongly convex, punctures uniseriate. Vestiture of erect scales, each scale about 5–6 times as long as wide, confused on disc, uniseriate on declivity, on declivity each scale two-thirds as long as distance between rows.

Female: Similar to male except frons convex, with setae sparse, inconspicuous; funicle without a brush; setae usually abraded on pronotum and on elytral disc.

Distribution: Costa Rica (?) to Brazil.

Brazil: RS-RGS Exp., 12°31'S, 51°46'W, Mato Grosso, 7-X-1968, RA. Beaver.

Colombia: Carton de Colombia forest 8 km S Colonia, Valle de Cauca, 9-VII-1970, 30 m, No. 631, *Protium nervosum*, SLW.

French Guyana: Cayenne.

Guiana: [Rio] Essequibo (type).

Peru: Tingo Maria, 6-7-IX-1942, E.J. Hambleton.

Hosts: *Protium nervosum*.

Biology: As described for *aeneipennis*.

Notes: The type series of *Hylesinus niger* Fabricius and *H. squamiger* Chapuis were examined, as well as 2 from French Guyane, and 18 from Brazil (Pernambuco). This species was previously reported from Costa Rica, Colombia, and Peru; the Costa Rican specimens were examined and are of *auricomus* Blandford, those from Colombia and Peru are of *tectus* Eggers.

Camptocerus orientalis Eggers

Camptocerus orientalis Eggers, 1943:244. Holotype ♂; Salobro, Prov. de Bahia, Brazil; DEI, Munchenberg (References in Wood & Bright c1992:320)

Diagnosis: Male frons without a conspicuous, median, epistomal tubercle below transverse carina; pronotum more distinctly reticulate on basal fourth; male declivity with scalelike setae extending to apex (setae on lower declivity confused, hairlike in *auricomus* Blandford); female striae on declivity less strongly impressed, punctures much smaller.

Male: Length 3.3–3.4 mm (female 3.7 mm), 1.9 times as long as wide, color very dark brown, setae variegated, pale and brown. Frons about as in *auricomus* except epistomal tubercle below carina absent; lateral patches of yellow hair in concave area less widely separated, setae slightly more abundant and longer. Pronotum about as in *auricomus* except surface more distinctly reticulate, punctures slightly larger, deeper. Elytra similar to *auricomus* except striae more distinctly impressed, punctures distinctly larger, larger than those of interstriae; interstitial setae on disc each about six times as long as wide, on lower declivity of erect scales, each about four times as long as wide, distinctly shorter than on disc.

Female: Similar to *auricomus* except weak transverse impression extending from epistoma only to upper level of eyes (much higher in *auricomus*).

Distribution: Brazil: Salobro, Bahia, 6-VII-1885, Gounelle.

Notes: The above treatment was based on the male holotype and on 1 male and 2 female paratypes with type data in DEI, Munchenberg.

Camptocerus auricomus Blandford

Plate XXXI

Camptocerus auricomus Blandford, 1896:125. Syntypes ♂ ♀; Chontales, Nicaragua, Bugaba and Volcan de Chiriqui, Panama; BMNH, London (References in Wood & Bright c1992:319)

Diagnosis: Distinguished by the confused, variegated interstitial setae; and by the weak, transverse male carina above the epistoma, and the median epistomal tubercle.

Male: Length 3.3–4.0 mm, 1.9 times as long as wide; color very dark brown, setae variegated pale and brown. Frons rather shallowly, broadly concave from carina at level of antennal insertions to vertex; surface minutely rugose at sides and below, pubescent areas finely, closely, shallowly punctured; median line, lateral areas, and area near carina glabrous, pubescent areas begin at vertex and extend seven-eighths distance toward carina, each pubescent area occupying middle half of distance from median line to lateral margin; carina weak, obtusely elevated, distinctly procurved, a strong, acute, median tubercle on epistoma below carina, surface weakly reticulate, almost impunctate; funicle with a strong brush of hair. Pronotum 0.86 times as long as wide; surface weakly reticulate, more strongly reticulate on anterior third, punctures rather small, deep, close, spaced by less than diameter of a puncture; setae on anterior third coarse, rather long, moderately close, on posterior areas very fine, rather short, easily abraded. Elytra about 1.0 times as long as wide, 1.1 times as long as pronotum; striae feebly or not impressed, punctures small, close; interstriae about four times as wide as striae, surface smooth, shining, punctures rather numerous, confused, each about two-thirds as large as those of striae. Declivity occupying posterior half or more of elytral length, convex, moderately steep; sculpture about as on disc. Vestiture of abundant, erect, variegated interstitial scales, each scale about four to six times as long as wide and equal in length to half width of an interstriae on disc, on lower declivity distinctly longer and very slender; almost hairlike bristles.

Female: Similar to male except frons convex, reticulate, vestiture very fine, sparse, carina and tubercle absent; without coarse setae on anterior third of pronotum; declivital setae scalelike as on disc.

Distribution: Nicaragua to Guiana and Venezuela.

Guiana: Cited by Wood & Bright c1992:319.

Venezuela: 20 km SW El Vigia, Merida, 21-XI-1969, 50 m, No. 149, tree limb, SLW.

Hosts: *Protium tenuifolium*, *P. sp.*

Biology: About as in *aeneipennis* Fabricius.

Notes: The above treatment was based on the male in the BMNH, London, that has generally been regarded as the holotype of *auricomus* Blandford and on 65 other specimens from Central America and 21 from Venezuela.

Camptocerus rectus Wood

Camptocerus rectus Wood, 1972:245. Holotype ♂; Venezuela: 40 km E Canton, Barinas; USNM, Washington (References in Wood & Bright c1992:320)

Diagnosis: Distinguished from *auricomus* Blandford by the subacute frontal carina (highest on median third); and by the absence of a median epistomal tubercle.

Male: Length 3.0–3.4 mm, 1.9 times as long as wide; color very dark brown, vestiture pale (when present). Frons similar to *auricomus* except upper area more

strongly concave, vestiture slightly shorter, more abundant; carina at level of antennal insertion straight, much stronger, highest on middle third. Pronotum about as in *auricomus* except surface strongly reticulate, setae usually abraded. Elytra similar to *auricomus* except surface reticulate, scales slightly shorter and much wider, each about 2–3 times as long as wide on both disc and declivity.

Female: Similar to male except frons convex, reticulate, moderately punctured, vestiture fine, sparse, short; posterior two-thirds of pronotum smooth, shining, glabrous.

Distribution: Venezuela: 40 km E Canton, Barinas, 8-III-1970, 70 m, No. 398, *Protium tenuifolium*, SLW; 9 km S Barancas, Barinas, 2-XII-1969, 150 m, No. 170, *Protium*, SLW; 10 km SE Miri, Barinas, 150 m, No. 298, *Protium tenuifolium*, SLW; 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 253, *Protium*, SLW.

Hosts: *Protium tenuifolium*, *P.* sp.

Biology: About as in *aeneipennis* Fabricius; limbs less than 10 cm in diameter were infested.

Notes: The above treatment was based on the entire type series of 40 specimens.

Camptocerus occidentalis Eggers

Camptocerus occidentalis Eggers, 1928:91. Lectotype ♂; Yungas, La Paz, Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:23 (References in Wood & Bright c1992:319)

Diagnosis: distinguished from *rectus* Wood by the more extensively, more deeply impressed male frons; and by the stronger, subacute, transverse male carina, its crest moderately concave.

Male: Length 3.6–4.1 mm, 2.0 times as long as wide; color dark reddish brown, elytral vestiture pale. Frons with a straight, subacute, transverse carina very slightly above level of antennal insertions, extreme ends highest, crest following a moderately concave course; area below carina to epistomal margin transversely, somewhat concavely impressed; area above carina to vertex broadly, rather deeply concave, surface reticulate, finely, obscurely punctured, median line glabrous, median half of each half ornamented by a dense patch of long hair from deepest point in concave area almost to its upper margin, longest setae not capable of extending to carina. Pronotum 0.90 times as long as wide; surface minutely reticulate, punctures rather small, close, deep, spaced by 1–22 diameters of a puncture; vestiture mostly abraded, anterior third with many long, slender setae. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; striae weakly impressed, punctures small, close; interstriae three times as wide as striae, surface smooth, shining, punctures small, confused, each about half as large as those of striae. Declivity occupying slightly more than posterior half, gradual, convex; surface reticulate, striae punctures mostly obsolete. Vestiture of rather abundant interstitial setae from base to apex, each slightly flattened and about equal in length to width of an interstriae.

Distribution: Bolivia to Peru.

Bolivia: Yungas, La Paz.

Peru: "Peru, Gehr. W. Mueller, Vermacht, 1909."

Notes: The above treatment was based on 2 male cotypes from Peru.

Camptocerus latipilis Schedl

Camptocerus latipilis Schedl, 1973:166. Holotype ♂; Benfica, Ananindeua, Para, Brazil; MZUSP, Sao Paulo (References in Wood & Bright c1992:319)

Diagnosis: Distinguished by the stout body; by the transverse male frontal carina located on the epistomal margin; and by the unique female elytral disc.

Female: Length 2.3–2.7 mm, 1.6–1.7 times as long as wide; color black, pronotum dark reddish brown. Frons convex, rugose-reticulate, punctures sparse, minute, subglabrous. Pronotum 0.80 times as long as wide; surface finely reticulate from base to anterior margin, punctures very small, shallow, moderately spaced; glabrous. Elytra 1.0 times as long as wide, 1.0 times as long as pronotum; surface reticulate; striae not impressed, punctures obsolete on basal one-fourth of elytral length (no indication of striae), small distinct, shallow from there to apex; basal third of elytral length with low, moderately broad, close, confused crenulations over striae and interstriae, becoming uniseriate on posterior half as broad tubercles. Vestiture abraded on basal half, present as slender bristles behind, each less than half as long as distance between rows, spaced within a row by distances slightly greater than length of a bristle.

Distribution: Brazil: Benfica, Ananindeua in Para; 69 km N Manaus, Amazonas, 7-XII-1979, G. Stevens.

Notes: The above treatment was based on 1 female that was compared by me to the male holotype.

Camptocerus inoblitus (Schedl)

Camptocerus inoblitus (Schedl), 1939:722 (*Loganius*). Holotype ♂; Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:319)

Diagnosis: Distinguished by the slender body form; by the strong, slightly procurved male frontal carina; and by the short, very fine, hairlike interstitial setae.

Male: Length 2.5–3.2 mm, 2.3 times as long as wide; color dark brown. Frons rather strongly concave from eye to eye from carina at level of antennal insertions to well above eyes, deepest on its lower third; surface rugose-reticulate, punctures minute, subgranulate, subglabrous except several bristles on lateral margin between carina and eye; carina strong, subacute, moderately procurved; shallowly sulcate below carina, almost smooth, with a few fine punctures, several bristles at lateral margin. Pronotum 1.0 times as long as wide; surface reticulate, punctures rather coarse, deep, spaced by about twice diameter of a puncture; glabrous behind, several bristles on anterior third; funicle with a small brush of long hair. Elytra 1.3 times as long as wide, 1.3 times as

long as pronotum; striae feebly impressed, punctures rather small, distinctly impressed; interstriae almost three times as wide as striae, surface almost smooth, with several short, impressed lines, punctures uniseriate, each two-thirds as large as those of striae. Declivity occupying posterior half of elytral length, broadly convex, moderately steep; surface with dense micropunctures, striae moderately impressed, punctures rather obscure, interstitial punctures uniseriate, slightly smaller than on disc. Vestiture of short, very fine, interstitial hair.

Female: Similar to male except frons convex, strongly reticulate, punctures shallow, obscure.

Distribution: Brazil: Nova Teutonia, Santa Catarina, 7-III-1950, F. Plaumann.

Notes: The above treatment was based on 3 males and 2 females from the type locality; 1 of these males was compared by me directly to the male holotype.

Camptocerus morio (Schedl)

Camptocerus morio (Schedl), 1952:348 (*Loganius*). Holotype ♂; Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:319)

Diagnosis: Distinguished from *inoblitus* (Schedl) by the smaller size; and by the much more strongly elevated median half of the male carina on the lower frons.

Male: Length 2.1 mm, 2.08 times as long as wide; color very dark brown. Frons as in *inoblitus* except slightly less strongly concave; transverse carina near level of antennal insertions much more strongly elevated on median half, less strongly elevated laterally. Pronotum 0.90 times as long as wide; surface of anterior half more nearly rugose-reticulate; punctures slightly smaller and more nearly circular; vestiture sparse on anterior half. Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; as in *inoblitus* except striae punctures smaller, not as deep, interstriae about three times as wide as striae, punctures greatly reduced, most obsolete. Declivity similar to *inoblitus* except striae more strongly impressed, punctures more nearly obsolete; interstriae more narrowly convex, punctures obsolete. Vestiture almost obsolete, a few very small, uniseriate hairlike setae scattered on posterior half.

Distribution: Brazil: Santa Catarina.

Notes: The above treatment was based on the male holotype from Brazil.

Camptocerus infedelis Wood

Camptocerus infedelis Wood, 1969:11. Holotype ♀; Peralta, Cartago, Costa Rica; USNM, Washington (References in Wood & Bright c1992:319)

Diagnosis: Distinguished by the smooth, shining pronotum and elytra; and by the sparse, distinctly flattened, longer, interstitial setae.

Female: Length 2.7–3.2 mm, 2.1 times as long as wide; color black. Frons about as in *inoblitus* (Schedl).

Pronotum 1.0 times as long as wide; surface reticulate on anterior half, smooth, shining behind, punctures fine, moderately close, spaced by about 2–4 diameters of a puncture; glabrous except several recumbent, stout setae on anterior fourth. Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; striae not impressed, punctures moderately large, not close, shallow, distinct; interstriae twice as wide as striae, shining, almost smooth, punctures minute, sparse, uniseriate. Declivity convex, rather steep; striae distinctly impressed, about as on disc. Vestiture abraded on disc, sparse setae on sides hairlike, those on disc flattened, each about 6–8 times as long as wide, each slightly shorter than distance between rows.

Distribution: Costa Rica: Peralta, Cartago, 10-III-1964, 500 m, No. 463, tree seedling, SLW.

Hosts: Tree seedling 1 cm in diameter.

Biology: The 2 known females and several larvae were removed from the same pith tunnel, 15 cm long, in a small, broken tree seedling. The larval cradles were made in a herringbone pattern, with 1 series above and the other below the egg tunnel at an oblique angle.

Notes: The above treatment was based on the female holotype and the female paratype.

Camptocerus opacicollis (Eggers)

Plate XXXII

Camptocerus opacicollis (Eggers), 1929:61 (*Loganius*). Holotype ♂; E Bolivia; NHMW, Wien (References in Wood & Bright c1992:319–320)

Camptocerus aquilus Wood, 1972:244. Holotype ♂; Brazil: 12°49'S, 51°46'W; BMNH, London

Diagnosis: Distinguished from *major* (Eggers) by the smaller size; by the smaller pronotal punctures; and by the much stouter interstitial scales.

Male: Length 1.8–2.5 mm, 2.1 times as long as wide; color black. Frons very similar to male *inoblitus* (Schedl). Pronotum 0.95 times as long as wide; surface strongly reticulate from base to anterior margin, subrugose on anterior fifth, punctures moderately coarse, deep, spaced by 1–4 diameters of a puncture; vestiture of sparse, recumbent, stout setae on anterior fourth. Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; striae feebly impressed, punctures small, distinct; interstriae about three times as wide as striae, almost smooth, punctures uniseriate, as large as those of striae. Declivity convex, moderately steep; striae distinctly impressed; interstitial punctures slightly smaller than on disc. Vestiture of uniseriate rows of erect scales, each scale 4–6 times as long as wide, about two-thirds as long as distance between rows, spaced within a row by length of a scale.

Female: Similar to male except frons convex (and about as in female *inoblitus*); pronotum shining on posterior half, reticulate in front; interstitial punctures more slender, each six to eight times as long as wide.

Distribution: Bolivia to Brazil.

Bolivia: E Bolivia [F. Woytkowski].

Brazil: 69 km N Manaus, Amazonas, 7-XII-1979, G. Stevens; RS-RGS Exp., 12°31'S, 5146'W, R.A. Beaver.

Notes: The above treatment was based on the male holotype of *Loganius opacicollis* Eggers, on the type series of *aquilis* Wood, and on 6 other specimens from Brazil.

Camptocerus major (Eggers)

Camptocerus major (Eggers), 1929:60 (*Loganius*). Holotype ♀; Chanchamayo [Peru]; NHMW, Wien (Synonymy and references in Wood & Bright c1992:319)

Camptocerus uniseriatus Schedl, 1972:54. Holotype ♂; Corcovado, Guanabara, Brazil; NHMW, Wien

Diagnosis: Distinguished from *opacicollis* (Eggers) by the larger body size; by the larger pronotal punctures (in the anterolateral areas), and by the much stouter interstitial setae.

Male: Length 2.7 mm (females 2.9–3.3 mm), 2.2 times as long as wide; color black. Frons as in male *opacicollis* except transverse carina very slightly less strongly elevated and longitudinal axis of concave area more distinctly longer than wide. Pronotum as in *opacicollis* except punctures distinctly larger especially on anterior third. Elytra about as in *opacicollis*, interstitial punctures feebly or not at all crenulate, interstitial setae more slender, each about six to eight times as long as wide, those on lower half of declivity shorter, more slender.

Female: Similar to male except frons convex, carina absent.

Distribution: Brazil to Peru.

Brazil: Corcovado, Guanabara; Jatahy, Goyas, VI-XI-1897.

Peru: [Rio] Chanchamayo [Dep. Junin].

Notes: The above treatment was based on 1 male and 3 females from Brazil.

Camptocerus annectens Wood, n. sp.

Camptocerus annectens Wood: Holotype ♀; Serra de Baturite, Ceara, Brazil; DEI, Muncheberg, designated below

Diagnosis: Female pronotum smooth, brightly shining on basal two-thirds, the punctures very small.

Female: Length 3.4 mm, 2.2 times as long as wide; color black. Frons as in female *major* (Eggers). Pronotum 1.0 times as long as wide; surface on posterior two-thirds smooth, brightly shining and very finely punctured, anterior third rather strongly reticulate, punctures slightly larger. Elytra as in *major* except interstitial punctures larger, as large as those of striae, their bases weakly to moderately elevated at least on anterior margin from base to apex; lower declivity reticulate; vestiture mostly

abraded, those present each about eight times as long as wide, declivital interstriae 7–9 each with a few slender bristles of moderate length.

Distribution: Brazil.

Type material: The female holotype was taken at Serra de Baturite, Ceara, Brazil, 1995, Gounelle. The holotype is in DEI, Muncheberg.

GENUS *SCOLYTOPSIS* BLANDFORD

Scolytopsis Blandford, 1896:120, 123. Type-species: *Scolytopsis puncticollis* Blandford, monobasic (References in Wood & Bright c1992:320)

Diagnosis: Distinguished from *Scolytus* by the near absence of an internal septum in the antennal club; by the deeply excised basal half of the costal margin of the elytra into which the metepisternum conspicuously expands; and by the abruptly flexed abdomen upward from the posterior margin of visible sternum 2.

Description: Length 2.0–3.5 mm, 2.1–2.3 times as long as wide; color dark reddish brown. Male frons usually flattened from epistoma to vertex (covered by a dense brush of long hair); female frons convex and punctured above, lower half variously impressed, vestiture sparse; antennal scape shorter than 7-segmented funicle, club moderately flattened, remnants of septum of procurved suture 1 usually visible. Pronotum large, unarmed, punctured, lateral margins marked by a raised costa. Elytra bases narrowly, strongly impressed along suture of basal one-fifth of elytra length; scutellum very small, rounded; striae distinctly impressed, rows of interstitial punctures impressed or not, often resembling those of striae; costal margin on basal half of elytral length deeply emarginate, metepisternum strongly, conspicuously expanded into this emargination; declivity rather weak, gradual, descending almost half distance to meet strongly ascending abdomen; abdomen ascending from posterior margin of visible sternum 2.

Distribution: Tropical America. Six species are listed by Wood & Bright (c1992:520–521) from Mexico (Veracruz) and Cuba to Argentina. Four species were recorded from South America. All 6 species are so poorly known that they are all treated below in the event that all might be found in South America.

Biology: The 3 species observed by me were phloeophagous and monogynous. All made biramous parental tunnels in the phloem that engraved the wood slightly. One species made longitudinal parental galleries, 2 made transverse galleries with respect to the grain of the wood. Larval mines were mostly in the phloem and were visible on peeled bark. They clearly resembled the engravings of *Scolytus*.

Key to the Species of *Scolytopsis*

1. Elytral surface smooth, shining from base to apex (posterior one-fifth sometimes with micropunctures, dull), striae and interstitial punctures usually smaller, ridges between rows of striae and interstitial punctures about equal in width to diameter of an adjacent puncture, interstitial setae more slender, usually longer; female frons less extensively convex, a conspicuous transverse impression present occupying as much as lower third of area below upper level of eyes 2
- Elytral surface with dense micropunctures (dull) from apex almost to base, striae and interstitial punctures rather coarse, ridges between rows of punctures narrow, their width equal to less than half diameter of an adjacent puncture; elytral setae shorter, stouter, flattened, each about eight times as long as wide or less; female frons more strongly convex to epistoma, setae shorter (usually), stouter 5
- 2(1). Elytral surface smooth, shining from base to apex, without micropunctures; interstitial setae moderately to very slender, longer, almost hairlike; striae and interstitial punctures smaller, less distinctly punctured 3
- Elytral surface near apex dull, with dense micropunctures; interstitial setae slightly flattened, at least 10 times as long as wide; female frons with transverse impression restricted to lower fourth, setae coarser, shorter 4
- 3(2). Interstitial setae very slender, almost hairlike, each at least 10 times as long as wide; male frons less broadly flattened, flattened area separated from eye by distance equal to two-thirds width of an eye, pubescent area narrower, setae less abundant, shorter, about one-eighth of pubescent area above upper level of eyes; punctures near base of pronotum disc larger, almost as large as adjacent interstitial punctures; Peru to S Brazil; 2.8–3.5 mm *peruanus* Eggers
- Interstitial setae rather slender, each about six to eight times as long as wide; male frons more broadly flattened to within one-fourth width of an eye from margin of eye, pubescent area wider, setae more dense, longer, about one-fourth of pubescence above upper level of eyes; punctures near base on pronotum disc small, less than one-third as large as adjacent interstitial punctures; female not seen; Brazil (Santa Catarina); 3.0 mm *brasiliensis* Eggers
- 4(2). Rows of striae punctures impressed, rows of interstitial punctures not impressed; pronotal punctures slightly larger; median callus on female frons subcarinate, frontal vestiture rather abundant, moderately long; brush of male setae on frons widely separated above into 2 areas; Mexico (Oaxaca); *Plumeria*, etc.; 2.5–3.1 mm *laticollis* Wood
- Rows of striae and interstitial punctures about equally impressed; pronotal punctures slightly smaller; median callus of female frons brightly shining, feebly elevated; frontal vestiture very short; Venezuela; *Terminalia guianensis*; 2.9–3.3 mm *orinocanus* Wood
- 5(1). Pronotum brightly shining from base to anterior margin, punctures minute on disc, become rather small near lateral margin; Argentina to Paraguay; 2.3–2.5 mm *toba* Wichmann
- Pronotum shining in median area on basal half, often reticulate on parts of anterior half and in lateral areas, punctures of moderate size on disc, becoming large in lateral areas; Cuba and Mexico (Veracruz) to Costa Rica and Brazil; *Laguncularia racemosa*, White Mangrove, etc.; 2.0–2.8 mm *puncticollis* Blandford

Scolytopsis peruanus Eggers

Plate XXXV

Scolytopsis peruanus Eggers, 1937:83. Lectotype ♀; Marcapata [Dep. Cuzco], Peru; USNM, Washington (References in Wood & Bright c1992:320)

Diagnosis: Distinguished by the smooth, shining surface of the elytra from base to apex; by the more slender,

longer interstitial setae; and by the stronger, more slender (narrower) impression on the lower half of the female frons.

Male: Length 2.8–3.5 mm, 2.3 times as long as wide; color very dark reddish brown. Frons broadly flattened from epistoma to well above upper level of eyes, separated from margin of eye by 0.5–1.0 times width of an eye, lateral thirds bearing a dense brush of long, fine,

rather dark hair from vertex to epistoma, brush narrowly divided on median line above, glabrous central area apparently becoming wider on lower half, weakly wrinkled near epistoma; epistoma with a small median brush at margin, immediately above margin with a small, short transverse carina below wrinkled area. Pronotum 1.0 times as long as wide; surface smooth, shining from base to apex, punctures small on disc, spaced by two to four diameters of a puncture, distinctly larger in lateral areas, punctures on disc near base almost as large as those of adjacent interstriae. Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; sides conspicuously constricted on basal third, caused by deep costal emargination on basal half into which metepisternum expands; surface smooth, shining from base to apex; striae narrowly, moderately impressed, punctures on 1 and 2 small, larger laterally; interstriae somewhat irregularly impressed along rows of small punctures (sulcate in some areas, some not), spaces (ridges) between striae and interstitial sulci about as wide as diameter of an adjacent puncture. Declivity convex, descending less than half distance to meet elytra, moderately steep; striae and interstitial sulci narrower, deeper than on disc, punctures smaller. Vestiture of interstitial rows of erect, very slender, almost hairlike setae, each seta almost equal in length to two-thirds distance between rows of setae, spaced within a row by slightly less than length of a seta.

Female: Similar to male except frons convex above, transversely impressed on more than lower half of area below upper level of eyes, surface mostly reticulate, rather coarsely, deeply, closely punctured, lower third with a weak median carina, epistomal transverse carina present, slightly larger than in male, setae sparse, fine, long, epistomal margin with small brush as in male.

Distribution: Brazil to Peru.

Brazil: "Southern Brazil, 1986," Jatahy, Goyas; Rio de Janeiro; "Mexican tobacco refuse intercepted at Paris" (actually from Brazil).

Peru: Marcapata, Dep. Cuzco, Eggers Collection 1948 (type).

Notes: The above treatment was based on the female holotype and on 20 other specimens from Brazil, and on the Rio de Janeiro and Mexican tobacco refuse specimens that were removed from the Blandford series of *puncticollis* Blandford.

Scolytopsis brasiliensis Eggers

Scolytopsis brasiliensis Eggers, 1931:16. Holotype ♂; Lages, Santa Catarina, Brazil; USNM, Washington (References in Wood & Bright c1992:320)

Diagnosis: Distinguished from *peruanus* Eggers by the stouter interstitial setae; by the more broadly flattened male frons (flattened area separated from margin of eye by a distance equal to less than one-fourth width of an eye); and by the much smaller pronotal punctures.

Male: Length 2.1 mm, 2.2 times as long as wide; color

dark reddish brown, elytral vestiture pale. Frons similar to *peruanus* except more broadly flattened, flattened area separated from margin of eye by distance equal to less than one-fourth width of an eye (more than 0.5–1.0 times this distance in *peruanus*); pubescent area 1.0 times as long as wide (1.2 times in *peruanus*), one-fourth of pubescent area above upper level of eyes (one-eighth in *peruanus*), setae longer and much more dense than in *peruanus*. Pronotum about as in *peruanus* except punctures smaller, those on disc near base about one-third as large as adjacent interstitial punctures. Elytra similar to *peruanus* except interstitial setae much more slender, each about 10 or more times as long as wide (about 6–8 times as long as wide in *peruanus*).

Female: Frons convex, coarsely punctured, shining, epistoma with a moderate median tubercle, lower half of frons with sparse, uniformly distributed long hair.

Distribution: Brazil: Lages [Santa Catarina], H. Fruhstorfer, leg. I-III-1887, vend., Eggers Collection 1948, type; Nova Teutonia, Santa Catarina, XII-1972, F. Plauermann; Jatahy, Goyaz.

Notes: The above treatment was based on the male holotype from Brazil.

Scolytopsis laticollis Wood

Scolytopsis laticollis Wood, 1968:14. Holotype ♀; 31 km SE Cameron, Oacaca, Mexico; USNM, Washington (References in Wood & Bright c1992:320)

Diagnosis: Posterior one-fifth of elytral length with dense micropunctures, rather dull; rows of striae punctures impressed, rows of interstitial punctures not sulcate; median callus on female frons subcarinate; dense male frontal setae divided on median line at vertex into two areas.

Male: Length 2.5–3.1 mm, 2.2 times as long as wide; color dark reddish brown. Frons similar to *brasiliensis* Eggers except with an obtuse, transverse hump just below upper level of eyes, dense reddish yellow brush of fine hair on lateral areas from vertex to epistoma, separated on vertex at median line by a distance equal to one-half width of space between eyes, epistomal carina apparently absent; median area apparently smooth, shining. Pronotum 0.90 times as long as wide, about as in *brasiliensis*. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides distinctly constricted on basal half; surface smooth, shining on basal four-fifths, with dense micropunctures on lower declivity; striae moderately, narrowly impressed, punctures rather small; interstriae not definitely sulcate, punctures almost as large as those of striae, spaces between striae and interstitial punctures about equal in width to diameter to an adjacent puncture. Declivity broadly convex, moderately steep, posterior margin finely serrate. Vestiture of rows of semierect interstitial setae, each seta distinctly stouter and shorter, length equal to one-half distance between rows.

Female: Frons similar to female *brasiliensis* Eggers except median line impunctate, moderately carinate from upper level of eyes to epistoma, vestiture more abundant, almost as long, otherwise as in male.

Distribution: Mexico: 30 km SE Cameron, 21-VI-1967, No. 79, *Plumeria*, and 2 other tree species, SLW.

Biology: A mining disturbance caused the destruction of more than 200 trees of several species resulting in a local epidemic of this species a month or 2 previous to the collection of dead stragglers. The biramous parental mines were transverse. Of the 3 or more tree species infested, only *Plumeria* was identifiable.

Notes: The above treatment was based on the type series of 15 specimens.

Scolytopsis orinocanus Wood

Plate XXXIV

Scolytopsis orinocanus Wood, 1971:18. Holotype ♀; Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:320)

Diagnosis: Posterior one-fifth of elytra surface with dense micropunctures, dull; both rows of striae and interstitial punctures about equally impressed; median callus on female frons smooth, shining, not elevated.

Male: Length 2.9–3.3 mm, 2.1 times as long as wide; color very dark brown, almost black. Frons broadly flattened from epistoma to well above upper level of eyes, lateral and dorsal margins with a dense brush of dark, long, fine hair; central area smooth, brightly shining, impunctate; median area above epistoma weakly wrinkled, without a carina, epistomal margin with a brush of hair. Pronotum as long as wide, about as in *laticollis* Wood except punctures distinctly larger. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; surface smooth, shining on basal four-fifths, with dense micropunctures on posterior one-fifth, dull; striae rather strongly, narrowly impressed, rows of interstitial punctures of equal size to those of striae, equally impressed, crests between striae and interstitial rows of punctures about equal in width to diameter of a puncture. Declivity and smooth posterior margin of elytra similar to *brasiliensis* Eggers. Vestiture of erect bristles, each stouter and slightly shorter than in *brasiliensis*.

Female: Similar to male except frons convex except lower third transversely impressed, punctures rather small, deep, close, median line impunctate, not elevated, vestiture short, stout, moderately abundant.

Distribution: Venezuela to Brazil (Goyas).

Brazil: Jatahy in Goyas, IX-1897.

Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 573, *Terminalia guianensis*, SLW.

Biology: The biramous parental galleries were longitudinal, parallel to the grain of the wood.

Notes: The above treatment was based on the type series of 49 specimens from Venezuela, and on 4 males from Brazil.

Scolytopsis toba Wichmann, n. status

Scolytopsis toba Wichmann, 1914:136. Holotype ♀; Santa Sofia, Paraguay; NHMW, Wien (Synonymy and references in Wood & Bright c1992:321)

Scolytopsis argentinensis Eggers, 1937:84. Lectotype ♂; Prov. Tucuman, Argentina; USNM, Washington, designated by Anderson & Anderson 1971:4 (References in Wood & Bright c1992:321). *New synonymy*

Scolytus bruchi Schedl, 1939:170. Lectotype ♂; orillas del Ignazu, Misiones (published record), Argentina; NHMW, Wien (References in Wood & Bright c1992:321). *New synonymy*

Diagnosis: Elytral surface with dense micropunctures from base to apex; pronotum brightly shining from anterior margin to base, punctures on pronotal disc minute, slightly larger in lateral areas; female frons strongly convex from epistoma to vertex.

Male: Length 2.3–2.5 mm, 2.1 times as long as wide; color very dark brown. Frons apparently as in *orinocanus* Wood, concealed by dense brush of long hair; longest setae on vertex extending well beyond epistomal margin. Pronotum about as long as wide; surface smooth, shining from anterior margin to base, punctures on disc minute, moderately large in lateral areas. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; striae moderately, narrowly impressed, punctures rather coarse, distinct; interstriae with punctures as coarse as those of striae, rows of punctures not impressed, space between striae and interstitial punctures equal in width to less than half diameter of an adjacent puncture; surface on more than posterior half with dense micropunctures, dull. Declivity convex, moderately steep, posterior margin weakly serrate in lateral areas; striae and interstitial punctures smaller than disc. Vestiture of rows of suberect, stout interstitial bristles, each about two-thirds as long as distance between rows, spaced within a row by length of a bristle, each seta about 10 times as long as wide.

Female: Similar to male except frons convex almost to epistoma, punctures small, deep, close, setae rather sparse, moderately long; median line on frons with a weak obtuse carina.

Distribution: Argentina to Paraguay.

Argentina: Prov. Tucuman, H. Richler.

Paraguay: Santa Sofia.

Notes: The above treatment was based on the female holotype of *toba* Wichmann, 1 male of *argentinensis* Eggers that I had compared directly to the male lectotype, and 1 other female, both from Argentina; and on the male holotype of *Scolytus bruchi* Schedl.

Scolytopsis puncticollis Blandford

Scolytopsis puncticollis Blandford, 1896:123. Lectotype ♂; Las Mercedes, Guatemala; BMNH, London, present designation (References in Wood & Bright c1992:321)

Scolytopsis cubensis Wood, 1961:48. Holotype ♀; Cayamas, Cuba; USNM, Washington

Diagnosis: Distinguished from *toba* Wichmann by the reticulation on the anterior and lateral areas of the pronotum, with the punctures distinctly larger.

Male: Length 2.0–2.8 mm, 2.2 times as long as wide; color dark reddish brown. Frons apparently as in *toba* (surface concealed by setae). Pronotum as long as wide; disc surface mostly smooth and shining, reticulate on anterior fourth and lateral areas, punctures on disc of moderate size. Elytra similar to *toba* except interstitial setae distinctly shorter, length equal to slightly more than half distance between rows, spaced within a row by almost twice length of a seta, each about four to six times as long as wide.

Female: Similar to male except frons convex almost to epistoma, frontal setae much shorter and less numerous than in *toba*.

Distribution: Mexico (Veracruz) and Cuba to Costa Rica and Brazil.

Belize: Stann Creek, Tabacco Range, 31-VII-1989 (4-89), white mangrove, C. Feller & W. Mathis.

Costa Rica: Canas, Guanacaste, 13-VII-1966, 50 m, liana, SLW.

Cuba: Cayamas, 5-IX, E.A. Schwarz.

Guatemala: Las Mercedes, Rio Maria Linda, Torola, Zapote (Blandford series).

Mexico: Mandinga, Veracruz, 12-III-1980, *Laguncularia racemosa*, S-047, T.H. Atkinson.

Argentina: orillas del Iguazu, Misiones.

Brazil: Jatahy in Goyas.

Hosts: *Laguncularia racemosa*.

Biology: This species was locally abundant in cut lianas of one species that were 8 cm in diameter. Parental galleries were biramous and transverse.

Notes: The above treatment was based on 1 specimen from Belize, 1 from Costa Rica, 3 from Cuba, 2 from Mexico, and 9 from Guatemala. The Cuban specimens were compared to the Blandford type series of *puncticollis*. The first specimen in the Blandford series, a male from Las Mercedes, Guatemala, is here designated as the lectotype of *puncticollis* Blandford.

GENUS *SCOLYTUS* GEOFFROY

Scolytus Geoffroy, 1762:309. Type-species: *Bostrichus scolytus* Fabricius, subsequent designation by International Commission on Zoological Nomenclature 1963:416, China 1963:416 (Synonymy and references in Wood & Bright c1992:321–382)

Ekkoptogaster Herbst, 1793:124. Type-species: *Bostrichus scolytus* Fabricius, subsequent designation by Hopkins 1914:8

Coptogaster Illiger, 1807:321. Type-species: *Bostrichus scolytus* Fabricius, subsequent designation by Hopkins 1914:118

Eccoptyogaster Gyllenhal, 1813:346. Type-species: *Bostrichus scolytus* Fabricius, automatic, invalid emendation of *Ekkoptogaster* Herbst

Scolytochelus Reitter, 1913:23. Type-species: *Ips multistriatus* Marsham, subsequent designation by Wood 1982:419

Ruguloscolytus Butovitsch, 1920:20. Type-species: *Bostrichus rugulosus* Muller, subsequent designation by Wood 1982:419

Archaeoscolytus Butovitsch, 1929:21, 23. Type-species: *Scolytus claviger* Blandford, nomen nudum, a species group name, no generic standing

Spinuloscolytus Butovitsch, 1929:21, 24. Type-species: *Ips multistriatus* Marsham, subsequent designation by Wood 1986:59, nomen nudum, a species group name, no generic standing

Tubuloscolytus Butovitsch, 1929:21, 33. Type-species: *Eccoptyogaster intricatus* Ratzeburg, subsequent designation by Wood 1986:59, a species group name, no generic standing

Diagnosis: Distinguished from *Scolytopsis* by the normal costal margin on the basal half of the elytra; by the normal metepisternum; and by the abdomen ascending from the posterior margin of visible sternum 1 to meet the weakly declivous elytra.

Description: Length 1.5–4.9 mm, 2.0–2.4 times as long as wide; color dark reddish brown to almost black. Frons usually sexually dimorphic, male usually less strongly convex, variously impressed or elevated, female flat to convex, both sexes with distinctive vestiture. Eye elongate, sinuate to shallowly emarginate on anterior mesal margin. Antennal scape short; funicle 7-segmented; club rather large, oval to obovate, flattened, either without sutures or suture 1 partly to completely septate, not externally grooved in most South American species. Pronotum large, lateral margins costate. Scutellum large, depressed, its apex subacute. Elytral bases depressed toward scutellum, weakly declivous behind; striate. Anterior coxae rather narrowly separated. Abdomen ascending abruptly from posterior margin of visible sternum 1 to meet apex of elytra; sternum 2 usually ascending abruptly, often impressed and armed in one or both sexes, sexually dimorphic in most species. In all native South American and several Central American species sternum 1 fused to sternum 2 with partial or total loss of intersegmental suture.

Distribution: Wood & Bright (c1992:321–382) record 120 species from North and South America, Asia, Europe, and northern Africa; 33 of these were recorded from South America. The South American species exhibit much greater diversity than do species in the remainder of the world.

Biology: The species are phloeophagous, with the entrance tunnel and biramous [uniramous in *rugulosus* (Muller)] parental gallery excavated by the female. This gallery is usually transverse, perpendicular to the grain of wood in the host, but may be longitudinal or diagonal in some species. In some species mating occurs on the bark surface and the male never enters the gallery system; in others the male spends from very little time up to the normal time in the parental gallery. Species in this genus are largely monogynous worldwide, except 1 species in Europe, and about one-third of the Central and South American species are bigynous. The parental gallery engraves the wood slightly to deeply, larval mines are almost entirely in the phloem where they may wander aimlessly or form definite patterns. Pupation occurs in the wood in *rugulosus*, but is usually in the phloem in South American species. The hosts of only a few South American species have been reported.

Key to the Species of *Scolytus*

1. Intersegmental line between visible sterna 1 and 2 fully formed, visible throughout its length; ventral profile of abdomen rising either gradually or abruptly to meet apex of elytra, sternum 2 armed or not, 3 to 5 never armed, sternum 2 not excavated (introduced to South America) 2
- Visible sterna 1 and 2 fused, intersegmental line usually obliterated, sternum 2 often ascending abruptly, excavated or sterna 2–5 sometimes armed by spines (native species) 4
- 2(1). Profile of abdomen ascending gradually from sternum 1–5 to meet descending elytra, none of sterna excavated or armed by spines; vestiture attaining base of elytra on all interstriae; Peru to Argentina (Europe, Asia, North America); *Malus*, *Pyrus*, *Prunus*, etc.; 1.5–2.7 mm *rugulosus* (Muller)
- Profile of abdomen ascending subvertically at base of sternum 2, elytra descend only slightly to meet abdomen; anterior margin of sternum 2 armed by a large median spine; elytra subglabrous on basal two-thirds 3
- 3(2). Abdomen at posterior margin of sternum 1 rising only slightly, profile of segments 2–5 more nearly convex, median spine on sternum 2 shorter, stouter, not longer than its basal width; punctures on pronotum disc distinctly larger; (Europe), Argentina, Brazil; *Ulmus*; 2.0–2.7 mm *kirschi* Skalitsky
- Profile of abdomen rising abruptly at base of sternum 2, remaining segments rise only slightly, median spine on sternum 2 much longer, more slender, much longer than its basal width; punctures on pronotum disc distinctly smaller; (Europe, Asia, North America), Argentina; *Ulmus*; 1.9–3.1 mm *multistriatus* (Marshall)
- 4(1). Frons in both sexes variously flattened to moderately convex or concave, surface longitudinally (often convergently), punctured or weakly to very strongly aciculate, never with a median tubercle or conspicuous elevation; basal margin of abdominal sternum 1 occasionally, transversely carinate, more commonly rounded, one or more sterna sometimes armed by spines; apparently all are monogynous 5
- Frons usually not aciculate, male with a conspicuous, large tubercle or obtuse median elevation; visible abdominal sternum 2 vertical, rising perpendicularly from 1, posterior crest of 1 sometimes acutely elevated; sternum 2 armed by a median spine, anterior (ventral) margin of this spine touching anterior margin of sternum 2, at least in male; interstitial punctures usually much smaller than those of striae, rows usually not impressed; apparently all species are bigynous . . . 27
- 5(4). Antennal club normal or elongate; striae punctures small interstitial punctures minute (less than one-fourth as large as those of striae); female sternum 2 armed by a large conically pointed or laterally compressed spine, 5 unarmed; male sternum 2 unarmed, sternum 5 sometimes with a bulla or large, slightly compressed median spine; elytra often bicolored 6
- Antennal club normal, less than twice as long as wide, only slightly longer than combined length of funicle and scape; interstitial punctures larger, never less than half as large as those of striae . . . 9
- 6(5). Junction between female abdominal sterna 1 and 2 rounded (not abrupt); female sternum 2 convex, a median spine about in middle of segment, spine conical, very sharply pointed, higher than its basal width; lateral margins of female sterna 3 and 4 unarmed by denticles; female sternum 5 flat to somewhat concave, not armed by a spine or callus; Suriname; 2.2 mm . . . *spinidens* Schedl
- Junction between female abdominal sterna 1 and 2 abrupt, 2 rather broadly flattened, 5 armed by a median spine or strong callus 7
- 7(6). Female frons more strongly convex, central half conspicuously reticulate, margins with moderately long, fine hair; antenna normal; female sternum 5 armed by a subglobular (slightly oval) median spine on anterior half of segment (not attaining anterior margin); Venezuela; 2.1 mm *bicolor* Eggers

—	Frons weakly to strongly aciculate, variously convex, central area without reticulation, with fine, longer hair	8
8(7).	Antennal club moderately elongate; female frons more strongly convex, rather coarsely aciculate, transverse impression above epistoma weak; spine on sternum 2 at anterior margin, slender, its base occupying about a third of segment length; bulla on sternum 5 much stronger; lateral margin of sterna 3 and 4 each armed by a small tubercle; Brazil (Gerais); 1.1 mm	<i>elongatus</i> Schedl
—	Antennal club greatly enlarged, more than twice as long as wide, 3 times as long as combined funicle and scape length; transverse impression on lower frons stronger and more extensive; spine on sternum 2 at anterior margin, its base occupying two-thirds of segment length, rather low, its highest point at posterior margin; bulla on sternum 5 weak; lateral margin of sterna 3 and 4 unarmed by a tubercle; Brazil (Sao Paulo to Bahia); 1.9–2.7 mm	<i>antennatus</i> Schedl
9(5).	Abdominal sternum 2 unarmed in either sex	10
—	Abdominal sternum 2 armed by a median spine or carina in one or both sexes	16
10(9).	Junction between abdominal sterna 1 and 2 rounded, with no indication of a transverse carina, broadly, strongly convex to suture between 2 and 3; lateral margins of 3 and 4 unarmed by tubercles, 5 convex, with its apical margin rounded (not abrupt or carinate); interstriae impressed almost equal to striae, punctures slightly smaller (male not seen); Brazil (Parana); 2.5 mm	<i>convexus</i> Schedl
—	Junction between abdominal sterna 1 and 2 abrupt, often weakly, transversely carinate, 2 ascending rather abruptly, lateral margins of 3 and 4 armed by a small spine (weak in <i>bolivianus</i>)	11
11(10).	Median half of 2 and all of sternum 5 almost flat, tubercle at lateral margin of 3 and 4 weak to absent; female frons rather strongly convex, aciculation weak but present, lateral areas and above ornamented by numerous, rather long, hairlike setae; interstriae not impressed on basal half, moderately impressed behind, punctures almost as large as those of striae	12
—	Sterna 2 and 5 at least slightly concave, lateral tubercle on 3 small to moderately large, usually pointed	13
12(11).	Larger species; punctures on pronotum disc very small; interstitial setae slender, almost hairlike, almost as long as distance between rows, extending from apex almost to base; frontal setae of female less abundant; Bolivia; 3.2 mm	<i>bolivianus</i> Schedl
—	Smaller species; punctures on pronotum disc rather small; interstitial setae stouter, almost two-thirds as long as distance between rows, mostly on posterior half; frontal setae of female much more abundant; Brazil (Gerais); 2.9 mm	<i>neofacialis</i> Schedl
13(11).	Sternum 3 armed by a transverse pair of large spines significantly displaced mesad from lateral margins in male, reduced to small nodules in female; Mexico (Oaxaca); <i>Combreton</i> ; 3.3–3.9 mm	<i>binodus</i> Wood
—	Spines on sternum 3 at lateral margins, small to moderately large	14a
14a(13).	Body size very small; striae punctures rather coarse, strongly impressed; vestiture on abdominal sterna short	14b
—	Much larger species, over 3.5 mm; interstitial punctures conspicuously smaller than those of striae and less strongly impressed; spine on lateral margin of sternum 3 comparatively small	15
14b(14a).	Interstitial punctures minute to obsolete; setae on abdominal sterna short, sparse, hairlike; base of sternum 2 rounded, rather coarsely punctured, not elevated, armed near apical margin by a transverse pair of moderately large spines, spines separated by one-fifth width of segment; segments 3–5 unarmed by tubercles, punctures very small; Brazil (Amazonas); 1.4 mm	<i>bispinatus</i> Wood

SCOLYTINI

- Strial and interstitial punctures subequal in size, moderately large, strongly impressed; setae on abdominal sterna of short, abundant scales; sternum 2 with anterior margin strongly produced, crest narrowly rounded (not costate), extended beyond posterior apex of sternum 2; sternum 2 armed on lateral margins by a rather large spine; Brazil (Jacareacanga); 1.5 mm *bicinctus* Schedl
- 15(14). Abdominal sternum 2 rather sparsely pubescent, setae shorter; male frons less strongly aciculate, setae on upper and lateral margins less numerous; Brazil (Amazonas); 3.8–4.0 mm *amazonicus* Schedl
- Sternum 2 ornamented by a dense brush of long golden hair, particularly on anterior half of segment; setae on upper and lateral margins of frons more abundant, longer; Brazil (Bahia); 4.8 mm *barbatus* Schedl
- 16(9). Male sternum 2 with median portion at base strongly, transversely elevated, its apex transversely carinate, without a median spine or longitudinal carina; lateral margins of visible sterna 2–4 with or without spines 17
- Male sternum 2 armed by a median spine on face or by a strongly elevated transverse costa at junction of 1 and 2, female with or without a spine or costa 19
- 17(16). (Female not seen); male frons minutely reticulate above, smooth below, with moderately abundant, minute punctures (no aciculation); male base of sternum 2 with a strongly elevated, transverse costa on median third, lateral margins of 2–4 each with a small spine; Brazil (Bahia) to Guiana; 3.5 mm *angustatus* Browne
- Male and female frons convergently aciculate from epistoma to at least half distance to vertex; male with a strongly elevated transverse costa at base of sternum 2 on median half of width of segment, lateral margins of 2–4 unarmed by spines; female with base of sternum 2 rounded, with a median, slightly elevated, punctured, subcircular callus; strial and interstitial rows of punctures equally impressed, costae between rows smooth, impunctate, each as wide as an adjacent puncture 18
- 18(17). Female frons flat on slightly narrower area (slightly mesad of eye) from epistoma to upper level of eyes, aciculation rather fine, setae much finer, half as long (north) to almost as long (south), less abundant; male interstitial setae shorter, restricted to posterior half of elytra; large liana; Costa Rica to Venezuela and Brazil; 3.2–3.9 mm *costellatus* Chapuis
- Female frons broadly flattened from eye to eye from epistoma to vertex, aciculation rather coarse as in male *costellatus*; male with uniseriate rows of fine, moderately long interstitial hair from base to apex, conspicuously longer near apex; Brazil; 3.9–4.0 mm *pseudocostellatus* Schedl
- 19(16). Male sternum 2 armed by a median spine at anterior margin of 2, sternum 4 armed by a small, median spine at posterior margin of segment; female abdomen unarmed by median spines 20
- Male and female sternum 2 armed by a median spine, other abdominal sterna unarmed by median spines 21
- 20(19). Median spine on male sternum 2 moderately compressed (laterally), longer than its basal (longitudinal) width, its apex narrowly rounded; male frons much more broadly convex, more strongly aciculate, vestiture much longer and more abundant; female abdomen unarmed; Costa Rica to Panama; 2.7–3.7 mm *nodatus* Wood
- Spine on male sternum 2 strongly compressed (laterally), its apex truncate, not as high as distance equal to basal (longitudinal) width; male frons more strongly convex, less strongly aciculate, vestiture shorter, less numerous; female not seen; Brazil (Sao Paulo); 2.6–2.9 mm *pinnatus* Eggers
- 21(19). Median spine on abdominal sternum 2 positioned at anterior margin of segment; vestiture of fine short hair in both sexes; male frons flattened (either weakly convex or slightly concave) 22

- Median spine on sternum 2 not attaining anterior margin of segment; male frons deeply excavated or spine on sternum 2 strongly, laterally compressed 23
- 22(21). Male frons with a weak transverse impression above epistoma, upper area transversely, weakly convex, punctures larger, rather dense, most longitudinally confluent; median spine on sternum 2 subquadrate, its height at anterior base equal to longitudinal base width, its anterior height about half its posterior height; Brazil (Parana); 3.0–3.2 mm *plaumanni* Wood
- Male frons rather strongly, transversely impressed above epistoma, upper area transversely, shallowly concave to upper level of eyes; frons rather densely, more finely punctured in both sexes, punctures in male small, few confluent, female strongly, convergently aciculate; median spine on abdominal sternum 2 quadrate, its height equal to longitudinal width; Brazil (Sao Paulo) to Paraguay; 3.5–4.5 mm *golbachii* Schedl
- 23(21). Male frons deeply, broadly, complexly excavated from epistoma to well above upper level of eyes; male sternum 2 armed by a large, cylindrical spine at middle of segment; Bolivia; ex “cuqui”; 4.3 mm *excavatus* Wood
- Frons not concave in either sex; spine on abdominal sternum 2 laterally compressed, not cylindrical 24
- 24(23). Setae on abdominal sternum 2 all very short, each palmately divided into 4 or more filaments; male sternum 2 moderately large, blunt, slightly compressed laterally; male frons with a brush of fine, rather long hair, setae distinctly longer and more abundant on vertex; Argentina to Brazil; 2.5 mm *caudatus* Eggers
- Setae on abdominal sternum 2 simple, undivided, either long or short 25
- 25(24). Median spine or carina on sternum 2 large, laterally compressed, occupying at least middle half of segment in both sexes (larger in male), its base not attaining either anterior or posterior margin of segment; frontal setae minute to absent in female, long and mostly in lateral areas below upper level of eyes in male; Mexico (Jalisco) to Costa Rica and Venezuela; large liana; 2.0–3.0 mm *cristatus* Wood
- Median spine or carina in male only, small, slightly, laterally compressed near posterior (dorsal) margin of sternum 2, female unarmed 26
- 26(24). Striae distinctly impressed, punctures small, distinct, interstriae not impressed on basal half, weakly impressed behind, punctures distinctly smaller than those of striae; male frons shining, finely, very closely punctured, rather conspicuously aciculate above, obscurely below, punctures separated by distances equal to less than diameter of a puncture, a narrow, median, impunctate line on lower half, setae finer, more uniformly distributed; color reddish brown (mature?); from Brazilian root of *Canella winterana* intercepted at New York (from Peru?); 3.2 mm *canellae* Wood
- Striae and interstriae about equally impressed from base to apex, punctures small, of about equal size; frons dull, aciculation obscure especially on dorsal half, punctures small, obscure, spaced on upper half by more than two diameters of a puncture, finer and closer below, vestiture fine, shorter and rather sparse in central area, longer and more abundant at margins; Venezuela; 3.0 mm *venezuelensis* Wood
- 27(4). Frons more strongly convex, at least upper half dull, strongly reticulate in both sexes (sometimes weak in *propinquus*); majority of female frontal setae below upper level of eyes; female abdominal sternum 2 either with or without a median spine at anterior margin, spine always present in male 28
- Frons usually less strongly convex, upper half appearing smooth at 80X, shining; majority of setae on female frons usually above upper level of eyes; sternum 2 always armed by a median spine on anterior margin in both sexes 32

SCOLYTINI

- 28(27). Male frons broadly flattened from epistoma to well above upper level of eyes, median elevation conical, moderately high, all setae on lateral margins; female frons less conspicuously flattened, subconcavely impressed below, vestiture of fine long, abundant hair on area below upper level of eyes, reticulation obscure in both sexes; female sternum 2 without a median spine, vestiture moderately long; male sternum 2 with a large spine and a conspicuous penicillate tuft of long hair on its posterior base, other setae on sternum 2 uniformly short; Mexico (Chihuahua, Veracruz) and Cuba to Costa Rica; *Inga paterno*, *Lonchocarpus*; 2.4–3.6 mm ***propinquus* Blandford**
- Upper half of frons more strongly convex and strongly reticulate in both sexes, male median elevation not as high, somewhat dorsoventrally compressed; setae on male sternum 2 a mixture of fine and coarse setae, not of uniform length, posterior base of median spine without a tuft of setae 29
- 29(28). Male sternum 2 with low, fine, palmately divided setae mixed among erect, coarse, rather short, simple setae, median spine large, subquadrate, laterally (moderately) compressed; setae on frons rather sparse, of moderate length; Nouvelle Granada (Colombia?) to Venezuela; ex “Haevea”; 2.5 mm ***proximus* Chapuis**
- Male sternum 2 with median spine smaller, more nearly cylindrical, setae mostly simple, a few bifid setae present in one species 30
- 30(29). Female sternum 2 subvertical (weakly convex), angle between 1 and 2 obtuse, median spine present; female frontal vestiture on lateral margins fine, long, rather sparse, about equal in abundance to dorsal half; Costa Rica; legume tree (*Lonchocarpus*?); 2.0–2.4 mm ***torulus* Wood**
- Female sternum 2 vertical, flat on anterior half, angle between 1 and 2 narrowly acute, median spine absent 31
- 31(30). Upper male frons more strongly convex, area at upper level of eyes smooth, shining, median elevation not as close to epistoma, without a connecting median crest; lateral and dorsal setae on male frons sparse, much shorter, not oriented into a definite line (female not seen); male sternum 2 less strongly, less extensively impressed, apparently no bifid setae present; Mexico (Yucatan); 2.3 mm ***marginatus* Chapuis**
- Upper male frons less strongly convex, area to and above upper level of eyes strongly reticulate; median elevation closer to epistoma and with a weak connecting crest to epistoma; lateral and dorsal setae on male frons arranged in a rather definite line, more than twice as abundant and twice as long; male sternum 2 more strongly, more extensively impressed, bifid setae present over most of surface (mixed with simple setae); Mexico (Nayarit); *Inga paterno*; 2.4–2.5 mm ***laetus* Wood**
- 32(27). Male and female frons with median tubercle small, sometimes obscure, surface punctured (to subaculate above) to median line in area above tubercle, vestiture usually less abundant, less conspicuous in both sexes; carina on sternum 2 very strongly, laterally compressed, low or strongly elevated, extending from anterior margin or near almost to middle of segment (female) or beyond middle (male) 33
- Male frons with median elevation varying from a small median carina to a moderate tubercle to a large, transverse, subcarinate elevation, area above elevation smooth, impunctate on a somewhat narrow to very broad area; spine on sternum 2 as long or much longer than longitudinal width of base in male, smaller in female, base extending from anterior margin rarely attaining middle of segment 35
- 33(32). Male with spine on abdominal sternum 2 displaced moderately from anterior margin, strongly elevated, length conspicuously greater than longitudinal basal width in male (not truncate), short and irregular in female; abdominal setae on 2–5 very short, almost scalelike; Peru; 3.2–3.4 mm ***peruensis* Schedl**
- Male abdominal spine on sternum 2 attaining anterior margin of segment, its apex truncate, not as high; abdominal setae hairlike 34

- 34(33). Setae on male frons mostly below upper level of eyes, upper brush almost entirely absent, setae sparse in female above and below; median spine on male sternum 2 not as high, both apical angles somewhat rounded, distal margin longitudinally arched, not parallel to base; Venezuela; "Hevecito"; 2.0–2.9 mm *barinensis* Wood
- Setae on male frons above upper level of eyes very long, dense, of dark reddish brown color; setae on lower areas shorter, yellowish (female without upper brush); median spine on male sternum 2 higher, quadrate, its distal angles abrupt, distal margin straight, parallel to base, much smaller; less definite in female; Colombia; 2.8–3.3 mm *carinatus* Chapuis
- 35(32). Median elevation on male frons a low, laterally compressed carina occupying middle third of area between epistoma and upper level of eyes, smooth, impunctate area above occupying about one-sixth area between eyes, vestiture rather abundant, long, mostly below upper level of eyes including median area; male spine on sternum 2 about twice as long as longitudinal width; female frontal carina similar to male, without impunctate area above, spine on sternum 2 half as large; Argentina to Brazil (Santa Catarina); 3.6–4.3 mm *novateutonicus* Schedl
- Median elevation on male frons tuberculate to broadly transverse, impunctate area above much larger, both elevation and impunctate area absent in female 36
- 36(35). Male median elevation on frons more nearly subconical, impunctate area above elevation narrower, less than half as wide as distance between eyes 37
- Male elevation on frons moderately to strongly transverse, impunctate area above elevation much wider, occupying more than half of space between eyes 39
- 37(36). Male frontal elevation rising more gradually on its lower slope, impunctate area above elevation narrower, distinctly less than a third as wide as distance between eyes; male vestiture less abundant, shorter; female frons with a strong brush of long hair above upper level of eyes; Brazil to Paraguay; 2.5–4.0 mm *submarginatus* Schedl
- Male frontal elevation rising more abruptly on lower slope, impunctate area above elevation equal in width to at least one-third distance between eyes; male vestiture more abundant, longer (female not seen) 38
- 38(37). Median tubercle on male frons low, dorsoventrally compressed on median third to a strong crest, tubercle transversely somewhat obscure, lateral areas below level of tubercle punctured, not all aciculate; female frons with a weak brush of long setae on dorsal margin extending to slightly above upper level of eyes, longest setae capable of extending almost one-fourth distance to epistomal margin, most setae on lower half of frons; striae and interstriae punctures minute, those of interstriae not in grooves; Brazil (Santa Catarina); 3.4–3.6 mm *obscuriceps* Wood
- Median tubercle on male frons strongly elevated, transversely acute, lateral areas below level of tubercle aciculate almost to epistoma; female not seen; striae and interstriae punctures moderately larger, both in impressed grooves; Brazil; 4.9 mm *nodulus* (Wichmann)
- 39(36). Male frontal elevation not as strong, subcarinate elevation occupying about one-sixth of distance between eyes; spine on male sternum 2 simple, moderately large, tapered from base to apex, usually with a penicillate tuft of hair at posterior base of spine; female frons with a dense brush of long hair above upper level of eyes, tips of some setae attain epistoma; Mexico (Veracruz) and Cuba to Venezuela; *Lonchocarpus margaritensis*, *L. sp.*, etc.; 2.1–3.3 mm *dimidiatus* Chapuis
- Male frontal elevation forming a strong, transverse carina on median half; spine on male and female sternum 2 rising to full height at its anterior margin, its posterior half abruptly stepped down to half or less of that height, its base extending behind middle of segment, similar but smaller in female; setae on female frons short, moderately abundant, without a conspicuous tuft on vertex; Brazil (Santa Catarina); 3.0–4.2 mm *thoracicus* Chapuis

Scolytus rugulosus (Muller)

- Scolytus rugulosus* (Muller), 1818:247 (*Bostrichus*). Syntypes, sex?; Odenbach, Deutschland; 1 at IRSNB, Brussels, several at DEI, Munchebereg (Synonymy and references in Wood & Bright c1992:364–370)

Diagnosis: Distinguished from endemic South American species by the visible, complete suture between abdominal sterna 1 and 2; by the gradual ascent of the profile of the abdomen to meet the elytra; and by the absence of abdominal spines.

Male: Length 1.5–2.7 mm, 2.2 times as long as wide; color very dark brown. Frons broadly convex, weakly impressed on lower fourth in median area, surface subshining, rather finely, convergently aciculate; punctures fine, obscure; vestiture of fine, moderately abundant, long hair. Pronotum 1.0 times as long as wide; surface smooth, shining, punctures coarse, close, deep, most separated by less than diameter of a puncture; glabrous, except a few hairlike setae on and near anterior and lateral margins. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; striae obscurely to distinctly impressed, punctures rather coarse, uniseriate, punctures without setae; interstriae about as wide as striae, punctures about equal in size to those of striae, rows of punctures often equally impressed, punctures bearing setae. Declivity convex, moderate; posterior margin finely serrate; striae and interstriae usually confused. Abdomen gradually ascending to meet apex of elytra; segments unarmed, without special sculpture.

Female: Similar to male except frons less distinctly impressed below; visible sternum 5 with subapical impression not as strong, more weakly concave.

Distribution: Europe, Asia, Africa, introduced into Australia, North and South America.

Argentina: Buenos Aires, 1858; Catamarca, Ciudad, III-1950, Martinez; Posadas, Misiones, R.A., XI-1945, Prosen; San Rafael, Mendoza, 10-I-1939, Prosen.

Brazil: Martinique, Sao Paulo, 29-X-1970, A. Moma; Nova Teutonia, Santa Catarina, I, II, III, XII 1955, I-1956, F. Plaumann.

Chile: Cordillero, Rio Clarillo, 25-X-6-XI-1988, C. Gonzales; Valparaiso, Villa Alemana, IV-1973, Solvercens; Chile, cortex pruni, 1882.

Peru: Tacana, Wille.

Uruguay: Cited by Wood & Bright (c1992:364).

Hosts: *Malus*, *Prunus*, *Pyrus*, etc.

Biology: An important species that is able to cause severe economic damage in domestic fruit orchards. Parental galleries are monoramous, longitudinal, and usually do not engrave the wood deeply. Larval mines wander at random in the phloem. Pupation occurs in the wood about 1 cm below the surface. They breed in cut, broken, or unthrifty limbs and branches, but can kill healthy stems under certain circumstances.

Notes: The above treatment was based on several hundred specimens from Europe, Asia, and North America and on 3 specimens from Brazil and 11 specimens from Chile.

Scolytus kirschi Skalitzky

Scolytus kirschi Skalitzky, 1876:110. Syntypes, sex?; Prague, Czechoslovakia; not located (Synonymy and references in Wood & Bright c1992:336–337)

Scolytus fasciatus Reitter, 1800:395. Holotype, sex?; Arexthal bei Orudbad; NHMB, Budapest

Eccoptogaster demaisonii Eggers, 1912:47. Syntypes ♂; Sicilia, Algeria, Hispania; Eggers Collection (USNM, Washington, or NHMW, Wien?).

Diagnosis: Distinguished from *multistriatus* (Marshall) by the less abruptly elevated (subvertical) abdominal sternum 2, its longitudinal and transverse profile much more distinctly convex; by the median spine on abdominal sternum 2 being smaller and distinctly displaced from the transverse costa at the base of sternum 2, this spine is usually smaller and more distinctly, laterally compressed; punctures on the pronotum disc are of larger average size.

Male: Length 2.0–2.7 mm, 2.3 times as long as wide; color dark reddish brown. Frons less strongly flattened than in *multistriatus*; punctures on pronotum variable but averaging larger than in *multistriatus*; elytral sculpture variable, variation similar to *multistriatus*. Junction of sterna 1 and 2 abrupt, transversely costate, 2 rising rather abruptly but face of segment moderately convex both transversely and longitudinally, base of median spine distinctly displaced dorsad from transverse costa at base of segment, spine smaller, more distinctly, laterally compressed than in *multistriatus*; sterna 3–5 less strongly impressed; sterna 3 and 4 never with small spines at lateral margins (usually present in *multistriatus*).

Female: Similar to male except frons more strongly, less extensively impressed; median spine on sternum usually smaller.

Distribution: Europe, Asia Minor, and N Africa, introduced into Argentina and southern Brazil.

Argentina: Oral report, not confirmed.

Brazil: Specimens examined, data not recorded.

Hosts: *Ulmus*, *Prunus*, *Fraxinus*, *Populus alba* in Europe.

Notes: Available reports from South America require confirmation. The above treatment was based on my European and North American series.

Scolytus multistriatus (Marsham)

Scolytus multistriatus (Marsham), 1802:54 (*Ips*). Syntypes, sex?; England; not located, probably at BMNH, London (Synonymy and references in Wood & Bright c1992:345–354)

Scolytus flavicornis Chevrolat, 1838:181. Syntypes, sex?; Pavis (Lombardy), Italy, not located, presumably at Liege

Scolytus ulmi Redtenbacher, 1849:361. Syntypes, sex?; Austria; not located

Scolytus javanus Chapuis, 1869:56. Holotype, sex?; Java; IRSNB, Brussels

Eccoptogaster orientalis Eggers, 1910:557. Lectotype ♂; Elisabethpol, Caucasiae rossicae; USNM, Washington, designated by Anderson & Anderson 1971:23

Scolytus nodifer Reitter, 1913:24. Holotype ♂; Walachei, Romania; NHMB, Budapest

Eccoptogaster abhorrens Wichmann, 1913:210. Holotype, sex?; Umgebung von Zara, Yugoslavia (?), Muller Collection

Eccoptogaster affinis Eggers, 1914:108. Holotype ♂; Macedonia; USNM, Washington

Scolytus therondi Hoffmann, 1939:36. Holotype, sex?; Nimes (Gard), France; MNHN, Paris

Scolytus papuanus Schedl, 1936:8. Syntypes, sex?; Kap Koenig Wilhelm, New Guinea; MNB, Berlin

Diagnosis: This species was introduced into South America and, consequently, has the intersegmental line between abdominal sterna 1 and 2 clearly marked to its lateral limits. It is also distinguished by the host and by the presence of a median spine at the anterior margin of subvertical abdominal sternum 2.

Male: Length 1.9–3.1 mm, 2.2 times as long as wide; color reddish brown, pronotum usually darker. Frons very broadly, distinctly convex from epistoma to vertex; surface shining, closely, longitudinally, somewhat convergently aciculate toward epistoma, crests rather fine and close to vertex, punctures obscure; vestiture of fine long hair over entire surface, longer and more abundant toward margins. Pronotum 1.0 times as long as wide; surface smooth, brightly shining, punctures rather coarse, close (spaced by about diameter of a puncture); glabrous except for a few setae near anterior margin. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; striae narrowly impressed, punctures small, very close, rather deep; interstriae about three times as wide as striae, smooth, shining, central third of each moderately sulcate from near base to near apex, punctures uniseriate (in interstitial sulci), punctures about half to two-thirds as large as those of striae. Declivity modest, punctures near apex confused; a few erect setae in declivital area. Abdominal sternum 2 subvertical on more than its anterior half, a coarse median spine on anterior one-

third; vestiture short, inconspicuous, moderately abundant, most setae divided into two parts.

Female: Similar to male except frons much more strongly convex, but similar.

Distribution: Asia, Europe, North America, etc., wherever elms are grown. Reported from South America (Argentina, Chile?), but specimens were not seen by me.

Hosts: *Ulmus* spp.

Biology: This species breeds in the limbs and boles of their host. They normally form feeding or hibernation maturation tunnels in twigs or small branches of green trees. They are a principal vector of the Dutch Elm Disease and are a major economic threat to the existence of elm species in some areas. An abundance of literature has been published on the biology of this species. For references see Wood & Bright (c1992:345–354).

Notes: The above treatment was based on several hundred North American and European specimens that were compared to the series of Eggers, Schedl, etc.

Scolytus facialis Schedl

Scolytus facialis Schedl, 1973:164. Holotype ♀; Maturaca, alto Rio Cauabun, Amazona, Brazil; MZUSP, Sao Paulo (References in Wood & Bright c1992:331)

Diagnosis: This species is not in the above key. The holotype of this species is a female, not a male as reported by Schedl. The exact placement of this species in classification cannot be determined until the male is found. The unique female is distinguished by the small striae and interstitial punctures, the interstitial punctures are uniseriate. Both sexes are essential to the correct placement in classification. In the above key it probably fits somewhere between couplets 9 and 20.

Female: Length 2.2 mm, 2.1 times as long as wide; color dark reddish brown. Frons convex, weakly, transversely impressed on lower third, more strongly convex above to vertex; median one-fourth moderately sulcate from near middle of frons to vertex; lateral thirds rather coarsely, closely punctured from epistoma to upper level of eyes, median third (median one-fifth near epistoma expanding to one-half above eyes) reticulate to transversely etched; lateral areas with fine, sparse, long hair (longest at lateral margins), lateral thirds above upper level of eyes with a small fringe of long reddish yellow hair; antennal club 2.0 times as long as wide. Pronotum 1.1 times as long as wide; surface smooth, shining, very finely punctured on posterior half of disc, punctures more than twice as large in lateral areas, becoming more than three times as large toward anterior margin. Elytra 1.2 times as long as wide, 1.1 times as long as pronotum; striae rather weakly impressed, punctures small, distinctly impressed; interstriae three or more times as wide as striae, smooth, shining, punctures uniseriate, very small on basal half (half as large as those of striae), irregularly larger on posterior half (some two or more times as large as those of striae); erect interstitial bristles slender, sparse (abrasion?), a few extend to anterior half.

Ventral surface of abdomen only partly visible on type; sternum 2 subvertical, its junction with 1 abrupt, 2–5 unarmed by spines; fine, moderately abundant, rather short hair uniformly distributed on 2–5.

Distribution: Brazil: Maturaca, Amazonas, alto Rio Cauaburi, 12-17-XII-1962, J. Bechyne.

Notes: The above treatment was based on the female holotype.

Scolytus spinidens Schedl

Scolytus spinidens Schedl, 1966:96. Holotype ♀; Suriname; NHMW, Wien (References in Wood & Bright c1992:377)

Diagnosis: Remotely allied to *bicolor* Eggers except abdominal sternum 5 without a median spine or callus; sternum 2 not ascending abruptly at its base, longitudinally convex, a small conical, acutely pointed spine rather remote from posterior margin; frons strongly convex, punctured, no aciculation; striae weakly impressed, interstitial punctures minute, mostly obsolete.

Female: Length 2.2 mm, 2.5 times as long as wide; color yellowish brown. Frons strongly, broadly convex; surface smooth, shining, punctures uniformly distributed, moderately coarse, deep, rather close; vestiture hairlike from epistoma to vertex, uniformly distributed, longer at sides and above; antennae removed from type. Pronotum 1.1 times as long as wide; widest at base, sides on basal half weakly arcuate and converging slightly toward broadly rounded anterior margin; surface smooth, shining, small and rather widely spaced on posterior two-thirds of pronotum length, a few setae on anterior fourth. Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; striae weakly impressed, punctures small (some obsolete near base); interstriae about three times as wide as striae, smooth, brightly shining, punctures minute, uniseriate except mostly obsolete on anterior two-thirds; posterior margin with an obscure tubercle in line with striae 2; a few hairlike setae near apex, mostly glabrous. Abdominal sternum 2 not ascending abruptly from 1, junction rounded, 2 convex, rather coarsely punctured, a small acutely pointed median spine placed slightly below middle remote from posterior margin; lateral margin of 3 and 4 unarmed by tubercles, 5 moderately concave, apical margin raised; setae on 2–5 sparse, hairlike.

Distribution: Suriname: “Niederl. Guayana.”

Notes: The above treatment was based on the female holotype from Suriname.

Scolytus bicolor Eggers

Scolytus bicolor Eggers, 1931:15. Holotype ♀; Guya. Ven. Mor.; MNB, Berlin (References in Wood & Bright c1992:325)

Diagnosis: Distinguished from *antennatus* Schedl by the normal antennae; by the reticulate female frons; by the much smaller punctures on the pronotum; and by the subglobular spine on female sternum 2.

Female: Length 2.1 mm, 2.4 times as long as wide; color reddish brown, basal two-thirds of elytra yellowish brown (clearly bicolored). Frons uniformly, rather strongly convex upward from epistoma, median half conspicuously reticulate, finely punctured on lateral fourths and toward vertex; vestiture of fine, long hair on margins. Antennal club 1.7 times as long as wide, of normal size, only slightly longer than combined length of funicle and scape. Pronotum 1.16 times as long as wide; surface smooth, shining; punctures on basal half minute, gradually transcending to small size on anterior one-fourth. Elytra about as in *antennatus* except posterior one-third reddish brown, anterior two-thirds yellowish brown. Sternum 2 with spine subglobular in one specimen, higher than wide in another; 5 with a rather strong, transverse callus near middle.

Distribution: “Guya. Ven. Mor.” [presumably Venezuela, taken by Moritz].

Notes: The area near the Moritz home at Colonia Tovar, Aragua, Venezuela, is presumed to be the type locality. The above treatment was based on the female holotype.

Scolytus elongatus Schedl

Scolytus elongatus Schedl, 1972:54. Holotype ♀; S. Caraca, S. Barbara, M. Gerais, [Brazil], 1450 m; NHMW, Wien (References in Wood & Bright c1992:329)

Diagnosis: Distinguished from *pinnatus* Eggers by the smaller size; by the very different abdominal spines; and by the presence of a conspicuous callus or bulla on abdominal sternum 5.

Female: Length 2.0 mm, 2.3 times as long as wide; color dark brown, pronotum almost black. Frons rather strongly convex from eye to eye from near epistoma to vertex; surface shining, rather strongly, convergently aciculate from epistoma to vertex, no punctures; vestiture of uniformly distributed, fine, long hair; sparse in central area, slightly more numerous at margins. Pronotum 1.1 times as long as wide; widest near base, sides weakly arcuate, converging toward broadly rounded anterior margin; surface smooth, shining, punctures on disc small, oval, 2–3 times larger near anterior margin, much larger in lateral areas; glabrous except sparse hair near anterior margin. Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; striae feebly impressed, punctures small; interstriae about four times as wide as striae, smooth, shining, punctures mostly obsolete, except a few on apical fourth, those present mostly larger than striae punctures; vestiture restricted to apical fourth, of fine, rather short hair. Abdominal sternum 2 subvertical, junction with 1 abrupt, almost transversely costate, a median spine slightly displaced from basal margin, its base extending almost half length of segment; spine laterally compressed, higher than basal (longitudinal) width, its apex slightly curved dorsad; 3 and 4 each with a very small tubercle at lateral margin; 5 weakly concave, its apical margin weakly elevated,

median fourth with a rounded bulla or callus slightly behind middle; vestiture of moderately abundant, fine, long hair.

Distribution: Brazil: S. Caraca, S. Barbara, M. Gerai, IV-1969, F.M. Oliveira; Nova Vicos, Bahia, 29-IX-1997, ethonal trap in *Eucalyptus grandis* stand, C.A.H. Flechtmann.

Notes: The above treatment was based on the female holotype from Brazil and on 1 other female.

Scolytus antennatus Schedl

Plates XXXV, XXXVI

Scolytus antennatus Schedl, 1935:272. Holotype ♀; Sao Paulo, Brazil; NHMW, Wien (References in Wood & Bright c1992:324)

Diagnosis: Distinguished by the very greatly enlarged and elongated antennal club in both sexes (more than twice as long as combined length of scape and funicle); male sternum 2 unarmed, sternum 5 with a large, median spine, female sternum 2 armed by a large, laterally compressed spine, sternum 5 unarmed.

Male: Length 1.9–2.7 mm, 2.1 times as long as wide; color reddish brown, elytra often bicolored. Frons rather broadly flattened from epistoma to well above upper level of eyes; surface rather finely, convergently aciculate; vestiture of long, moderately abundant hair. Antennal club very long, twice as long as combined length of funicle and scape. Pronotum 1.0 times as long as wide; surface smooth, shining, punctures rather small, spaced by one to three diameters of a puncture, conspicuously larger in anterolateral areas; a dozen long, coarse setae and several small, fine setae near anterior margin. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; surface smooth, shining, striae feebly to not impressed, punctures distinct, moderately large on basal half, small to very small behind; interstriae two (anterior) to four (posterior) times as wide as striae, punctures very minute, uniseriate. Declivity very weak; posterior margin smooth. Sternum 2 oblique, angle with 1 obtuse, narrowly rounded, dull to sternum 5; sternum 5 with a large, weakly compressed median spine on anterior half; vestiture moderately abundant, of medium length from sternum 2–5.

Female: Similar to male except frons convex on upper half, moderately, transversely impressed below, aciculation about as in male, vestiture less abundant but much longer.

Distribution: Brazil: Bahia, Cepec, Ilheus, I-III-1961, blacklight, Kaston; Mato Grosso, Xingu, XI-1961, Avarenga & Bokermann.

Notes: The above treatment was based on 12 specimens 1 of which I compared directly to the holotype.

Scolytus convexus Schedl

Scolytus convexus Schedl, 1972:53. Holotype ♀; Bocaiuva, Parana, Brazil; NHMW, Wien (References in Wood & Bright c1992:328)

Diagnosis: The convex, rounded female abdomen and equally impressed striae and interstriae suggest this

species is allied to *costellatus* Chapuis, however, the frons is very different. Correct placement must await discovery of the male. The female frons resembles that of female *costellatus*.

Female: Length 2.5 mm, about 2.0 times as long as wide (elytra spread); very dark brown. Frons broadly convex, lower two-thirds on median half somewhat flattened; surface shining, finely, convergently aciculate from epistoma to vertex; vestiture moderately abundant, uniformly distributed, of fine, long hair from epistoma to vertex. Pronotum 0.95 times as long as wide; sides widest one-third pronotum length from base, moderately arcuate, converging toward broadly rounded anterior margin; surface smooth, shining, punctures small, oval, moderately abundant; glabrous. Elytra about 1.1 times as long as wide (spread on type), about 1.1 times as long as pronotum; striae narrowly, moderately impressed, interstriae similarly impressed except mostly obsolete on basal fourth, costae between grooves narrowly rounded (not acute); vestiture mostly abraded, a few interstitial setae near apex rather stout. Abdominal sternum 2 convex, junction with 1 rounded, without a costa or median elevation; surface rather dull, punctures rather small, deep, moderately close, their interiors shining; sternum 5 slightly convex, its apical margin semiabrupt, not elevated.

Distribution: Brazil: Bocaiuva (Parana), 25°08', 49°04', 1000 m, DEI, Muncheberg, 1963, F. Plaumann.

Notes: The above treatment was based on the female holotype.

Scolytus bolivianus Schedl

Scolytus bolivianus Schedl, 1966:97. Holotype ♀; Bolivia; NHMW, Wien (References in Wood & Bright c1992:325)

Diagnosis: Allied to *convexus* Schedl except abdominal sternum 2 subvertical, junction with 1 abrupt, transversely, weakly costate; female frons rather strongly convex, somewhat similar to *convexus*; elytra resembling *convexus* but impressions weaker, less extensive.

Female: Length 3.2 mm, 2.1 times as long as wide, color very dark brown, elytra reddish brown. Frons of type covered by resin except for a small area at center, apparently moderately convex, shining, aciculate about as in *convexus* (no flattened area), vestiture apparently similar to female *convexus* except more abundant in lateral and dorsal areas. Both antennae missing from type. Pronotum 1.1 times as long as wide, about as in *convexus*. Elytra 1.1 times as long as wide, 1.0 times as long as pronotum; striae weakly narrowly impressed, punctures small, distinct; interstriae smooth, shining, grooves equally impressed on posterior fifth to those of striae, impression decreasing anteriorly, almost obsolete on basal half of elytral length; interstitial setae suberect, rather stout, each equal in length to about one-half to two-thirds distance between rows, rather regularly placed on posterior third, sparse to absent on anterior half.

Distribution: Bolivia: "Bolivien."

Notes: The above treatment was based on the female holotype.

Scolytus neofacialis Schedl

Scolytus neofacialis Schedl 1976:60. Holotype ♀; Varginha, M. Gerais, Brazil; NHMW, Wien (References in Wood & Bright c1992:354)

Diagnosis: Distinguished from *bolivianus* Schedl by the smaller punctures on the pronotum disc; by the shorter interstitial setae; and by the much more abundant setae on the female frons.

Female: Length 3.2 mm, 2.1 times as long as wide; color very dark brown, elytra dark reddish brown. Frons broadly, moderately convex from eye to eye from epistoma to vertex, convergently rather finely aciculate from epistoma to vertex, shining; vestiture on lateral and dorsal margins of long, moderately abundant, incurved hair; hair in central area shorter; finer, less abundant. Pronotum 1.04 times as long as wide; smooth, shining; punctures very small, oval on disc, more than twice as large and subrugose on anterior one-sixth; glabrous, except sparse, short hair near anterior margin. Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; striae very narrowly, distinctly impressed on posterior half to two-thirds, usually not impressed toward base, punctures very small, distinct; interstriae impressed on posterior fourth almost equal to striae, impression discontinued near middle, surface smooth, shining; interstitial setae almost hairlike, in uniseriate rows on posterior half, obsolete toward base. Abdominal sternum 2 subvertical, junction with 1 abrupt, transversely subcostate, its surface almost smooth, sparse punctures minute, obscure; 5 weakly concave, apical margin weakly elevated; abdominal setae on 2–5 of moderately abundant, long hair (abdomen very similar to *bolivianus* except setae much longer).

Distribution: Brazil: Varginha, M. Gerais, II-1972, M. Alvarenga.

Notes: The above treatment was based on the female holotype. A male placed under this name in the Schedl material at Wien is actually a misidentified female of *submarginatus* Schedl.

Scolytus binodus Wood

Scolytus binodus Wood, 1982:230. Holotype ♀; Uxpanapa, Oaxaca, Mexico; USNM, Washington (References in Wood & Bright c1992:325)

Diagnosis: Distinguished by the presence of a transverse pair of widely spaced, large spines (male) or conspicuous nodules (female) on visible abdominal segment 3.

Male: Length 3.0–3.9 mm, 2.0 times as long as wide; color dark brown. Frons flattened (very weakly convex) from epistoma to vertex; surface shining, finely, longitudinally aciculate, aciculation converging toward median line below; vestiture of fine rather long hair; setae on

lateral and upper margins much longer. Pronotum 1.0 times as long as wide; surface smooth, brightly shining, punctures minute on disc, distinctly larger in lateral areas especially on anterior half; glabrous except for a few hairlike setae near anterior margin. Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; striae narrowly, rather deeply impressed, punctures small, distinct; interstriae three to four times as wide as striae, surface smooth, brightly shining, punctures minute, uniseriate, rows not impressed on basal half, on posterior half rows impressed almost equal to striae, rows of stout hairlike setae on posterior half only. Declivity moderate, posterior margin smooth. Sternum 2 subvertical on anterior half, a row of large punctures and setae at anterior margin, another transverse row at middle of segment, smooth, shining, impunctate between these rows; sternum 3 dull, armed by a widely spaced, transverse pair of large, cylindrical, blunt spines, punctures absent; 4 and 5 dull, densely punctured, 5 subconcavely impressed, setae only at apical margin.

Female: Similar to male except spines on sternum 3 reduced to moderately large, rounded nodules.

Distribution: Mexico: Uxpanapa, Oaxaca, 24-V-1981, 120 m, S-282, *Combreton* sp., A. Equihua.

Notes: The above treatment was based on the type series of 11 specimens and on 10 other topotypic specimens that bear the type data. This unique species might occur in South America.

Scolytus bispinatus Wood, n. sp.

Scolytus bispinatus Wood: Holotype ♂?; Armalus, Amazonas Timber, S.A. forest, Brazil; MZUSP, Sao Paulo

Diagnosis: This is the smallest and most slender known member of this genus known to me; it is easily distinguished from the distantly related *bicinctus* Schedl by characters in the above key and in the description below

Male (?): Length 1.4 mm, 2.6 times as long as wide; color yellowish brown. Frons rather broadly convex, a feeble transverse impression above epistoma; smooth, shining, punctures small, close, weakly subrugose, a weak median tubercle about one-third distance above epistoma toward upper level of eyes; vestiture of minute, rather numerous, hairlike seta; both antennae missing from type. Pronotum 1.16 times as long as wide; sides on basal three-fourths feebly arcuate and converging slightly toward rather narrowly rounded anterior margin; surface smooth, brightly shining, punctures very small, slightly longer than wide, rather widely spaced except anterior fifth much more coarsely, closely punctured; glabrous. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; disc occupying basal 70 percent of elytra length; striae feebly impressed, punctures moderately large, rather strongly impressed; interstriae smooth, brightly shining, almost twice as wide as striae, uniseriate punctures minute, half or more obsolete.

Declivity descending moderately about one-third distance to meet abdomen; surface reticulate, stria and interstria punctures obsolete except near base; glabrous. Abdominal sterna 1 and 2 fused, suture not visible, base of 2 rounded, not elevated, rather coarsely punctured, armed near apical margin by a transverse pair of moderately pointed spines, spines separated by one-fifth width of segment; segments 3–5 unarmed by tubercles, punctures very small, setae sparse, short, almost hair-like.

Distribution: Brazil (Amazonas).

Type material: The male (?) holotype was taken in Brazil at Armalus, Amazonas Timber, S.A., 2 MC Jous, 1987, No. 015 G1, A.P. Santos. The holotype is in the Museu de Zoologie, Universidade de Sao Paulo, Sao Paulo.

Scolytus bicinctus Schedl

Scolytus bicinctus Schedl, 1972:52. Holotype ♂; Jacareacanga, Para, Brazil; NHMW, Wien (References in Wood & Bright c1992:325)

Diagnosis: Distinguished by the very small body size; by the rather coarse, strongly impressed stria and interstria punctures; and by the short, almost scalelike, setae on abdominal sterna 2–5.

Male (?): Length 1.5 mm, 2.3 times as long as wide; color reddish brown. Frons broadly, rather strongly convex from epistoma to weak transverse impression immediately above epistoma; surface obscurely reticulate to rugose-reticulate and closely, deeply, moderately punctured over entire area; vestiture of sparse, fine, short hair; antennal club with acutely angulate groove for suture 1 clearly marked. Pronotum 1.04 times as long as wide; surface smooth, shining, punctures on disc small, oval, rather close, becoming two to three times as large on anterior fifth and lateral areas; vestiture reduced to sparse hair near anterior margin. Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; striae irregularly, weakly impressed, punctures moderately coarse, close, strongly impressed; interstriae obscurely impressed (grooves about equal in width to those of striae); stria and interstria punctures about equal in size. Minute stria hair present near apex; interstria setae uniseriate, semirecumbent, uniseriate, very short at base, becoming longer near apex, length mostly equal to less than half distance between rows. Abdominal sternum 2 with anterior margin very strongly produced, crest narrowly rounded (not acutely costate), extending beyond level of posterior apex of sternum 2; lateral margin of 3 armed by a coarse, sharply pointed spine; 5 moderately concave, apical margin moderately elevated; surface of 1–5 shining, punctures rather coarse, deep, very close, with abundant setae very short, stout, some almost scalelike.

Distribution: Brazil: Jacareacanga, Para, VI-1970, F.R. Barbosa [M. Alvarenga Collection].

Notes: The above treatment was based on the holotype from Brazil, presumed to be a male.

Scolytus amazonicus Schedl

Scolytus amazonicus Schedl, 1972:52. Holotype ♂; Manaus, Amazonas, [Brazil]; NHMW, Wien (References in Wood & Bright c1992:322)

Diagnosis: Allied to *barbatus* Schedl but smaller; it lacks the conspicuous brush of hair on male sternum 2, and the male frons is less strongly reticulate, with setae on the lateral areas less numerous.

Male: Similar to female except frons weakly convex from eye to eye from epistoma to vertex, shining, rather coarsely, convergently aciculate, punctures not evident; frontal vestiture of fine, long hair; setae rather sparse and shorter in central area, longer and more abundant in lateral and dorsal areas.

Female: length 3.8–4.0 mm, 2.2 times as long as wide; color dark reddish brown. Frons moderately convex on upper half, a distinct transverse impression on lower half; rather coarsely, convergently aciculate from eye to eye from epistoma to vertex, no punctures; hairlike vestiture rather sparse, short. Pronotum 1.1 times as long as wide; surface smooth, shining, punctures very small on disc, 3 times as large near anterior margin, larger in lateral areas; mostly glabrous, sparse setae near margins. Elytra 1.14 times as long as wide, 1.0 times as long as pronotum; striae distinctly, narrowly, rather shallowly impressed, punctures small, distinct; interstriae smooth, shining, narrowly impressed, almost equal to striae on posterior fourth, feebly or not impressed on anterior half, punctures minute, less than one-third as large as those of striae; interstria setae rather stout, most restricted to posterior third. Abdominal sternum 2 vertical, anterior margin slightly elevated, costate; surface dull, subreticulate, punctures on posterior half rather small, distinct, uniformly distributed, on anterior half unequally distributed, some close and confluent between small impunctate areas; 5 closely punctured, subconcave, apical margin elevated; vestiture of sparse, short coarse hair, partly abraded.

Distribution: Brazil: Manaus, Amazonas; “Brasilia, Boa Vista.”

Notes: The above treatment was based on the female holotype and on 1 male, both from Brazil.

Scolytus barbatus Schedl

Scolytus barbatus Schedl, 1976:59. Holotype ♂; Encruzilhada, 980 m, Bahia, Brazil; NHMW, Wien (References in Wood & Bright c1992:325)

Diagnosis: Distinguished by the large size; and by the conspicuous, dense tuft of long, yellow hair on the anterior half of male sternum 2.

Male: Length 4.8 mm, 2.2 times as long as wide; color very dark reddish brown. Frons very weakly convex eye to eye from epistoma to vertex, with surface rather coarsely, convergently aciculate; vestiture of long hair, sparse in central area, rather abundant on sides and above. Pronotum 1.1 times as long as wide; surface

smooth, shining, punctures on disc small, oval, about three times as large near anterior margin, larger in lateral areas; glabrous except for sparse setae near anterior margin. Elytra 1.2 times as long as wide, 1.1 times as long as pronotum; sculpture as in *amazonicus* Schedl except striae less strongly impressed on anterior half, setae less numerous. Abdominal sternum 2 subvertical, junction with 1 abrupt, transversely subcostate, costa not elevated; anterior half of 2 densely ornamented by a tuft of long yellow hair, less abundant on middle third, subglabrous and impunctate near posterior margin; 3 armed at lateral angle by a small denticle, anterior half with rather short, stout setae of moderate abundance, posterior half glabrous and impunctate; 4 and 5 closely, finely punctured and ornamented by very short setae, apical margin of 5 elevated.

Distribution: Brazil: Encruzilhada, 980 m, Bahia.

Notes: The above treatment was based on the male holotype from Brazil.

Scolytus angustatus Browne

Scolytus angustatus Browne, 1970:575. Holotype ♂; Santarem, Bahia, Brazil; BMNH, London (References in Wood & Bright c1992:324)

Diagnosis: Possibly allied to *costellatus* Chapuis, distinguished by total absence of frontal aciculation; by the much shorter, transverse costa at the base of abdominal sternum 2 (only a third as wide as segment); and by the presence of small spines at the lateral margins of abdominal segments 2–4.

Male: Length 3.5 mm, 2.0 times as long as wide; color reddish brown. Frons convex, upper half feebly flattened, lower half with a weak median crest; surface weakly reticulate above, almost smooth, shining below, punctures small, moderately abundant below, very small and less abundant above; vestiture hairlike, moderately abundant, rather long, a moderate epistomal brush present. Pronotum 1.0 times as long as wide; surface smooth, brightly shining, punctures oval, very small, moderately abundant, only slightly larger in lateral areas; glabrous. Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; striae narrowly, rather weakly impressed from base to declivity; interstriae about three times as wide as striae, punctures mostly half as wide as those of striae, uniseriate, on some interstriae punctures positioned in a weak groove (not always indicated); punctures near weak declivity larger, deeper, confused. Vestiture of uniseriate interstitial rows of rather stout, erect setae, some rows extending to basal half (2, 5, 7), others only near declivity (1, 3, 4, 6). Anterior margin of sternum 2 very strongly carinate on median third of segment width; sterna 3–5 unarmed, dull, with sparse, short setae.

Distribution: Guiana to Brazil.

Brazil: Santarem, Bahia; Campus do INCA, Manaus, Amazonas, 1-XII-1986, R.L.S. Abreu.

Guiana: Upper Courantyne River, IX-1935, G.H. Hudson (B.M. 1936-360).

Notes: The above treatment was based on the male holotype, 1 other male from Brazil, and 1 badly crushed male of obviously the same species from Guiana.

Scolytus costellatus Chapuis

Plates XXXVII, XXXVIII

Scolytus costellatus Chapuis, 1869:58. Holotype ♀; Nova Fribourg, Brazil; IRSNB, Brussels (References in Wood & Bright c1992:328)

Diagnosis: Pronotum clearly longer than elytra; striae and interstriae equally sulcate and punctured; male sternum 2 with a subacute transverse costa on median two-thirds, female sternum 2 convexly rounded, with a round, punctured, median callus, costa absent.

Male: Length 3.2–3.9 mm, 1.8 times as long as wide; mature color black. Frons flat from eye to eye from epistoma to vertex; surface shining, aciculation fine, weak above, stronger and converging slightly on lower half; vestiture of fine hair shorter, rather sparse in central area, much longer, more numerous on margins. Pronotum 0.96 times as long as wide; surface smooth, brightly shining, punctures rather small, spaced by one to three diameters of a puncture on disc, much larger in lateral areas; glabrous, except for a few fine hairs near anterior margin. Elytra 0.88 times as long as wide, 0.94 times as long as pronotum; striae and interstriae equally sulcate and punctured, smooth, shining, punctures fine, distinct. Declivity weak, posterior margin smooth. Sternum 2 subvertical, its anterior margin subacutely costate on median two-thirds, punctures rather coarse, uniformly distributed; sterna 3–5 dull, punctures abundant, fine; vestiture sparse, short, inconspicuous.

Female: Similar to male except frons weakly convex, setae finer, shorter, much less numerous; sternum 2 with costa absent, basal margin rounded, anterior half with a submarginal, punctured, subcircular, moderately high, median callus.

Distribution: Costa Rica to Brazil.

Brazil: Nova Fribourg.

Venezuela: 40 km E Canton, Barinas, 8-III-1970, No. 346, large liana, SLW.

Hosts: A liana 10 cm in diameter.

Biology: Adult galleries biramous and transverse.

Notes: The above treatment was based on the female holotype, 77 specimens from Costa Rica, and from Venezuela.

Scolytus pseudocostellatus Schedl

Scolytus pseudocostellatus Schedl, 1937:159. Holotype ♂; Sao Paulo, Brazil; NHMW, Wien (References in Wood & Bright c1992:357)
Scolytus strigipennis Schedl, 1976:60. Holotype ♀; Brazil; NHMW, Wien (References in Wood & Bright c1992:377). *New synonymy*

Diagnosis: Distinguished from *costellatus* Chapuis by having the female frons more broadly flattened from eye to eye from epistoma to vertex, the aciculation rather coarse as in male *costellatus*; and by the larger average size; frontal setae longer (as in *costellatus*)

frontal setae are short in northern part of range but gradually increase in length, those from southern Brazil about equal to this species.

Male: Similar to female except sternum 2 radically different; abdominal sternum 2 subvertical, rising abruptly from costate anterior margin, costa on median two-thirds, weakly costate on its median third, more strongly elevated laterally, vertical face of sternum 2 smooth, shining, coarsely, deeply closely punctured, without a median callus (a female character).

Female: Length 3.9–4.0 mm, 1.8 times as long as wide; color black. Frons strongly, broadly flattened from eye to eye from epistoma to vertex, shining, closely aciculate from eye to eye, aciculation slightly finer than in male; vestiture of fine, long hair, longer and more abundant on margins (more numerous and longer in male). Pronotum 0.72 times as long as wide; surface brightly shining, punctures small, uniformly distributed in central area, larger near lateral margins; glabrous. Elytra 1.04 times as long as wide, 1.04 times as long as pronotum; striae and interstriae equally, strongly impressed, punctures small, obscure, some confluent, costae between grooves subacute, continuous; interstriae bearing uniseriate rows of fine, erect hair from base to apex, each seta equal in length to distance between rows. Abdominal sternum 2 with basal margin rounded, transverse costa absent, face moderately convex, with a subcircular, punctured median callus near anterior margin as in *costellatus* female.

Distribution: Brazil: Uloatuba, Sao Paulo, V-VI-1967, P.C. Montonchet; Sao Paulo, "female" (male holotype of *pseudocostellatus*); "Alte Sammlung, Brasilien" (female type of *strigipennis*).

Hosts: Probably a large liana.

Notes: The above treatment was based on the male holotype of *pseudocostellatus*, on 1 other male, both from Brazil, and on the female holotype of *strigipennis*.

Scolytus nodatus Wood

Scolytus nodatus Wood, 1969:12. Holotype ♂; Santa Ana, San Jose, Costa Rica; USNM, Washington (References in Wood & Bright c1992:354–355)

Diagnosis: Frons convergently aciculate in both sexes; male sternum 2 with a median spine, 2 and 3 each with a small lateral spine, 4 with a median, subglobular spine, 5 unarmed except for apical carina.

Male: Length 2.7–3.7 mm, 1.6 times as long as wide; color dark reddish brown, pronotum almost black. Frons finely, rather deeply, convergently aciculate from epistoma to vertex; vestiture hairlike, fine, rather long, mostly on margins. Pronotum 1.03 times as long as wide; posterior four-fifths smooth, shining, with fine punctures moderately spaced, anterior one-fifth minutely etched, punctures shallow, more than twice as wide as on disc. Elytra 1.03 times as long as wide, 0.96 times as long as pronotum; striae very narrow, distinctly impressed, punctures minute, distinct; interstriae shining, narrowly,

distinctly impressed only near declivity, weakly impressed to middle, punctures minute, equal in size to those of striae; vestiture of erect, slender, hairlike setae on all interstriae, each equal in length to less than two-thirds distance between rows. Sternum 2 with anterior margin subacute, with a large median spine on anterior third; lateral margins of 2 and 3 each with a small tubercle, 4 with a median subglobular spine on posterior third of 4, apical margin of 5 carinate; vestiture hairlike, rather short, moderately abundant on segments 2–5.

Female: Similar to male except median spines on abdominal segments 2 and 4 absent, those on lateral margins of 2 and 3 present, subapical carina on 5 present; setae on 2–5 longer.

Distribution: Costa Rica to Panama.

Hosts: A large, spiny liana.

Biology: Parental galleries were biramous and longitudinal.

Notes: The above treatment was based on the type series of 26 specimens. It probably occurs in South America.

Scolytus pinnatus Eggers

Scolytus pinnatus Eggers, 1928:94. Holotype ♂?; Blumenau, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:356)

Diagnosis: Distinguished by the comparatively small size; by the occurrence of a median spine or tubercle at the posterior margin of male abdominal sternum 4; and by the compressed, quadrate shape of the median spine on male sternum 2.

Male (?): Length 2.6–2.8 mm, 2.0 times as long as wide; color dark reddish brown. Frons moderately convex eye to eye from epistoma to vertex, surface rather coarsely, convergently aciculate, no punctures; vestiture moderately abundant, fine, rather short, uniformly distributed. Pronotum 0.94 times as long as wide; surface smooth, shining, punctures on disc small, oval, about three times as large near anterior margin, larger in lateral areas, glabrous except near anterior margin. Elytra 1.1 times as long as wide, 1.0 times as long as pronotum; striae shallowly, narrowly impressed, punctures small, distinct; interstriae impressed on posterior third about equal to striae, interstitial impressions ending at or near middle of elytra length; interstitial setae mostly on posterior third of elytra length, of fine hair. Abdominal sternum 2–5 dull, punctures obscure to obsolete; 2 vertical, its junction with 1 abrupt, weakly, transversely costate, a coarse denticle on lateral end of posterior margin, a large lateral compressed median spine at anterior margin, its base extending to middle of segment, spine truncate apically, its basal width slightly greater than its height; sternum 3 armed at lateral margin by a rather coarse denticle; 4 armed by a small median denticle at posterior margin; 5 shallowly concave, apical margin weakly elevated; vestiture on 2–5 of sparse, short, fine hair.

Distribution: Brazil: Blumeneau (type); Itanhaen, 14-VIII-1949, E.X. Rabello.

Notes: The above treatment was based on the holotype and on 1 other specimen, both of the same sex (presumed to be males), from Brazil.

Scolytus plaumanni Wood, n. sp.

Plate XLI

Scolytus plaumanni Wood: Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; USNM, Washington, designated below

Diagnosis: Distinguished from *golbachii* Schedl by the smaller size; by the different sculpture of the frons in both sexes; and by the different size and shape of the median spine on abdominal sternum 2 in both sexes.

Male: Length 3.0–3.2 mm, 2.0 times as long as wide; color yellowish brown (mature?). Frons weakly, convexly flattened on median three-fourths from vertex to moderate transverse impression immediately above smooth, shining epistoma; surface shining, punctures very small, confluent, rather weakly aciculate; vestiture of fine, uniformly distributed setae of moderate, uniform length. Pronotum and elytra about as in *golbachii* except punctures of pronotum averaging slightly larger, punctures of striae and interstriae smaller. Abdominal sternum 2 with surface obscurely subreticulate, punctures slightly larger than *golbachii*; median spine moderately, laterally compressed, its base attaining anterior margin of segment, base extending almost to middle of segment; anterior height about equal to longitudinal basal width, its crest oblique, highest at anterior margin, descending obliquely to half this height at posterior margin; vestiture of fine long hair.

Female: Similar to male except frons more strongly convex, particularly toward vertex; surface sculpture similar to male (not forming strong carinae as in female *golbachii*; spine on sternum 2 slightly smaller.

Distribution: Brazil (Santa Catarina).

Type material: The male holotype, female allotype, and 1 female paratype were taken at Nova Teutonia, Santa Catarina, Brazil, III-1941, F. Plaumann. The holotype and allotype are in the DEI, Muncheberg; the paratype is in the U.S. National Museum, Washington.

Scolytus golbachii Schedl

Scolytus golbachii Schedl, 1951:288. Syntypes ♂; Pto. Bemberg, Misiones, Argentina; NHMW, Wien (References in Wood & Bright c1992:331)

Diagnosis: Median pair of aciculations on male frons conspicuously enlarged; neither striae nor interstriae impressed except weakly near apex.

Male: Similar to female except frons moderately, transversely, impressed immediately above epistoma, upper area flattened on median two-thirds to slightly above or well above upper level of eyes (variable in males at hand), punctures fine, abundant, most in subaciculate, confluent rows; vestiture of fine, moderately long hair.

Female: Length 3.3–4.4 mm, 1.9 times as long as wide; color very dark reddish brown. Frons convex, convergently aciculate (punctures obscure, very small), median pair of aciculations conspicuously enlarged on upper two-thirds; vestiture rather sparse, of fine, long, uniformly distributed hair. Pronotum 1.0 times as long as wide; as in *nodatus* Wood. Elytra 1.0 times as long as wide, 0.96 times as long as pronotum; striae and interstriae as in *nodatus* except hairlike interstitial setae restricted to odd-numbered interstriae, present only near declivity. Sternum 2 subvertical, smooth, shining, punctures small, shallow, median line near anterior margin armed by a large subcylindrical, somewhat blunt spine; segments 3–5 apparently with surface similar to 2 (not visible), 2 to 5 with fine, moderately abundant, long hair.

Distribution: Argentina to Brazil and Paraguay.

Argentina: Pto. Bemberg, Misiones, 12-29-I-1945, Hayward-Willink-Goldbach.

Brazil: Rondon, Parana, VIII-1952, 24°38'B, 24°07'L, F. Plaumann.

Paraguay: Hohenau, Jacob.

Notes: The above treatment was based on 1 male that was compared by me to a female paratype of *golbachii* Schedl, and on specimens from Brazil and Paraguay.

Scolytus excavatus Wood, n. sp.

Plate XXXIX

Scolytus excavatus Wood: Holotype ♂; Warnes near Santa Cruz [de la Sierra], Bolivia; USNM, Washington, designated below

Diagnosis: Male distinguished by the deeply, complexly excavated frons; and by sternum 2 bearing a large median denticle at middle of segment.

Male: Length 4.3 mm, 1.7 times as long as wide; color black. Frons deeply concave eye to eye from epistoma to well above upper level of eyes, upper area flattened from margin of concavity to vertex; main cavity deeply excavated on median one-fifth from epistoma to upper margin of concave area, this deep inner cavity smooth, shining, its margins densely pubescent, more sparsely pubescent at abrupt margin near eye; upper flattened area (above main concavity) densely, finely punctured and ornamented by a marginal tuft of long, dark hair (this tuft interrupted at median line); antennal club rather small. Pronotum as long as wide; surface smooth, shining, punctures small, mostly spaced by one to three diameters of a punctures, not larger in lateral areas; glabrous except a few, fine, hairlike setae near anterior margin. Elytra 0.90 times as long as wide, 0.90 times as long as pronotum; striae distinctly, rather narrowly impressed, punctures small, distinct; interstriae about four times as wide as striae, punctures very small, uniseriate. Declivity very weak; posterior margin smooth. Sternum 2 with basal margin rounded, subvertical, convex, middle of segment with a large, cylindrical, blunt spine; surface of 1–5 dull, punctures small, obscure; sternum 5 moderately concave, apical margin acute; vestiture of

short, fine, moderately abundant hair, longer between spine and anterior margin.

Distribution: Bolivia.

Type material: The male holotype was taken at Warones, near Santa Cruz [de la Sierra], Bolivia, X-1952, ex "Cuqui," Munro #127a, 53 1170. The holotype is in the U.S. National Museum, Washington.

Notes: The above treatment was based on the male holotype.

Scolytus caudatus Eggers

Plate XXXVII

Scolytus caudatus Eggers, 1931:35. Lectotype ♂; Rio de Janeiro, Brazil; USNM, Washington, designated by Anderson & Anderson 1971:9 (References in Wood & Bright c1992:327)

Scolytus pseudocaudatus Eggers, 1931:35. Holotype, sex?; Sao Paulo, Brazil; NHMW, Wien

Scolytus conidens Browne, 1970:574. Holotype ♀; Bahia, Brazil; BMNH, London (References in Wood & Bright c1992:328). *New synonymy*

Diagnosis: Female sternum 2 subvertical, angle with sternum 1 abrupt (about 90 degrees); sternum 2 with a small spine at middle of segment, setae on this segment all short, each palmately divided into about 4 filaments.

Male: Length 2.5 mm, 1.8 times as long as wide; color dark reddish brown. Frons from epistoma to vertex broadly, rather strongly convex; surface shining, densely, uniformly, rather coarsely punctured from eye to eye; vestiture apparently of rather sparse, short, fine hair in central area, much longer and more abundant on margins (especially above), tips of longest setae capable of reaching slightly beyond middle of frons length. Pronotum as long as wide; surface smooth, shining, punctures minute on posterior area of disc, distinctly larger toward anterior margin and much larger toward lateral margins; glabrous except for a few setae near anterior margin. Elytra 0.94 times as long as wide, 0.94 times as long as pronotum; striae very narrow, not impressed at base, distinctly impressed on posterior two-thirds, punctures very small, distinctly impressed; interstriae about five times as wide as striae, punctures uniseriate, rows impressed, almost equal in width and depth to striae, punctures very slightly smaller than those of striae; two or three short setae near apex on some interstriae. Declivity very weak; posterior margin smooth. Sternum 2 subvertical, meeting sternum 1 at an abrupt angle; 2 with a rather large, subcylindrical, blunt spine at middle of segment, surface of 2 rather coarsely, closely punctured; vestiture on 2 uniformly very short, each seta palmately divided into three to five filaments; sternum 3–5 dull, apparently obscurely punctured (setae abraded?).

Female: The holotype of *conidens* Browne appears to be this species; the frons is more strongly convex and the setae above the upper level of the eyes are much more dense.

Distribution: Argentina to Brazil.

Argentina: Misiones, Member, 12-I-1943, Hayward et al.

Brazil: Rio de Janeiro; Sao Paulo.

Notes: The above treatment was based on 1 female from Argentina that was compared by me to the Schedl series. The female holotype and all paratypes of *conidens* Browne were examined and quite clearly are synonymous with *caudatus* Eggers.

Scolytus cristatus Wood

Plate XXXVIII

Scolytus cristatus Wood, 1969:12. Holotype ♂; Lower Rio Tempisque, Guanacaste, Costa Rica; USNM, Washington (References in Wood & Bright c1992:328)

Diagnosis: Abdominal sternum 2 armed by a strong, laterally compressed spine (occupying middle half of segment) that does not attain either the anterior or posterior margin, the short setae simple, hairlike; male setae on frons mostly below upper level of eyes.

Male: Length 2.0–3.0 mm, 2.0 times as long as wide; color dark reddish brown. Frons with a weak transverse impression immediately above epistoma, almost flat from there to upper level of eyes; surfaces shining, moderately, convergently aciculate from epistoma to vertex; vestiture mostly below upper level of eyes, much longer and more abundant on and near lateral margins. Pronotum 1.0 times as long as wide; surface smooth, shining, punctures small, deep on disc, much larger on lateral fourths; glabrous. Elytra 1.1 times as long as wide, 1.1 times as long as pronotum; striae and interstriae narrowly, about equally impressed (except interstriae feebly impressed on basal third or less), punctures small, distinct, those of striae and interstriae about equal in size; interstitial punctures (near weak declivity) with a few short setae; posterior margin smooth. Sternum 2 subvertical, with a strong, median, laterally compressed carina occupying central half of segment, its highest point near posterior margin; surface of 2 with coarse, circular punctures, their interiors reticulate; setae moderately abundant, short, rather stout, simple.

Female: Similar to male except frons much more strongly convex, setae sparse, minute; carina on sternum 2 slightly smaller.

Distribution: Mexico (Jalisco) to Costa Rica and Venezuela.

Venezuela: 9 km S Barrancas, Barinas, 2-XII-1969, No. 159, "Batatillo" (a liana), SLW.

Hosts: Lianas "batatillo" and *Clematis* sp.

Biology: Transverse, biramous parental galleries in the phloem. The host stems were 4 to 10 cm in diameter.

Notes: The above treatment was based on the type series of 29 specimens from Costa Rica, 5 other specimens from Costa Rica, 9 from Mexico (Jalisco and Colima), and 51 from Venezuela.

Scolytus canellae Wood, n. sp.

Scolytus canellae Wood: Holotype ♂; in Barbasco root from Brazil intercepted at New York; USNM, Washington, designated below

Diagnosis: Male sternum with a minute tubercle near posterior margin, female unarmed; interstriae not impressed on basal half, weakly impressed behind; male frons closely punctured, becoming aciculate above.

Male: Length 3.2 mm, 1.7 times as long as wide; color reddish brown (mature?). Frons transversely flattened eye to eye, longitudinally rather weakly convex from epistoma to vertex; surface shining, closely, subaciculate punctured on lower half, punctures less definite, more coarsely aciculate above; median line just below middle weakly elevated and rather narrowly impunctate. Vestiture of abundant, fine, long hair uniformly distributed, slightly longer at margins. Pronotum 0.96 times as long as wide; surface shining, punctures moderately coarse, rather deep, mostly spaced by two to three diameters of a puncture; glabrous. Elytra 0.90 times as long as wide, 0.90 times as long as pronotum; striae moderately, narrowly impressed, punctures rather coarse, distinct; interstriae at least twice as wide as striae, smooth, shining, punctures uniseriate, each half as wide as those of striae, rows not impressed on basal half, distinctly impressed on posterior fourth; odd-numbered interstriae each with a sparse row of stout setae (a seta about equal in length to width of an interstriae. Sternum 2 with basal half vertical, junction with 1 abrupt (about 90 degrees), surface almost smooth, dull; punctures close, shallow (interiors shining), spaced by one-half to twice diameter of a puncture; a very small, median spine near (not on) posterior margin; sternum 5 with a strong submarginal costa on entire posterior margin; setae on 2–5 erect, rather stout, moderately abundant.

Female: Similar to male except frons similarly but more finely sculptured; sternum 2 without a spine.

Distribution: Brazil to Peru.

Type material: The male holotype and female allotype were taken in Barbasco root (?=*Canella* sp.) from Brazil intercepted at New York, 13-V-1940, lot No. 40-10064; 1 male paratype is from cube root from Peru intercepted 21-V-1960 at New York, 163400 lot 60-15792, Sedgwick et al. The holotype, allotype, and paratype are in the U.S. National Museum, Washington.

Scolytus venezuelensis Wood, n. sp.

Scolytus venezuelensis Wood: Holotype ♂; Union Orinoco-Ugueto TFA (Alto Orinoco), Venezuela; USNM, Washington, designated below

Diagnosis: Allied to *canellae* Wood except striae and interstriae about equally, narrowly impressed; male frons with punctures more widely spaced, not aciculate above, surface rather dull, obscurely subreticulate.

Male: Length 4.3 mm, 1.7 times as long as wide; color almost black. Frons rather dull, very obscurely reticulate, punctures small, rather deep, obscurely subaciculate in lateral areas, a slight median summit below middle. Vestiture sparse, dark, long, more abundant on lateral margins below upper level of eyes. Pronotum as in *canellae*. Elytra similar to *canellae* except striae and

interstriae narrowly sulcate to base, setae on odd-numbered interstriae on declivity. Abdomen with sterna as in *canellae*.

Distribution: Venezuela (Ter. Amazonas).

Type material: The male holotype was taken at "Union Orinoco-Ugueto TFA, 7-X-1951, Exp. Fco Ven., Alto Orinoco" [Ter. Amazonas, Venezuela]. The holotype is in the U.S. National Museum, Washington.

Scolytus propinquus Blandford

Scolytus propinquus Blandford, 1896:121. Syntypes, sex?; Mexico, Veracruz and Teapa in Tabasco, and Guatemala, Chacaoj; BMNH, London (Synonymy and references in Wood & Bright c1992:357) *Scolytus penicillus* Schedl, 1973:165. Holotype ♂; Veracruz, Mexico; NHMW, Wien

Diagnosis: Male vertical sternum 2 with vestiture abundant, very short, a large median spine at anterior margin, a penicillate tuft of long hair arising from its posterior basal margin, female without spine or tuft of hair; and setae hairlike, longer.

Male: Length 2.4–3.6 mm, 1.8 times as long as wide; color dark reddish brown, pronotum almost black. Frons almost flat from eye to eye from epistoma to slightly above upper level of eyes; surface subshining, obscurely reticulate at 80X (not at 40X), punctures small, not close, a moderately large, conical, median spine midway between epistomal margin and upper level of eyes; central area almost glabrous, lateral margins with a dense row of erect, long hair from near epistoma to well above upper level of eyes (not present on median half of upper margin). Pronotum 1.0 times as long as wide; surface smooth, shining, punctures on disc very small, rather close, spaced by 1–3 diameters of a puncture, coarse in lateral areas; glabrous except for a few setae near anterior margin. Elytra 0.93 times as long as wide, 1.0 times as long as pronotum; striae not impressed except some weakly near declivity, punctures small, rather strongly impressed; interstriae about twice as wide as striae, smooth, shining, punctures about one-half to two-thirds as large as those of striae; odd-numbered interstriae with a few setae. Abdominal sternum 2 vertical, angle with segment 1 abrupt (about 90 degrees); surfaces of segments 1–5 dull, closely punctured, bearing very short, abundant, stout hair; 2 with a large, somewhat laterally compressed, median spine at anterior margin, its posterior base bearing a conspicuous, large tuft of long, yellow hair; carina on posterior margin of sternum 5 subacute, not strongly elevated.

Female: Similar to male except frons without a spine, area below upper level of eyes, from eye to eye, with a large tuft of long hair; spine and tuft on sternum 2 absent, setae on 2–5 hairlike, longer.

Distribution: Mexico (Chihuahua to Veracruz) and Cuba to Costa Rica.

Hosts: *Inga paterno*, *Lonchocarpus* spp.

Biology: Transverse, biramous parental galleries are bored in limbs and boles larger than 5 cm in diameter.

Two females are normally associated in a gallery with each male.

Notes: The above treatment was based on 96 specimens, 2 males of which were compared to Blandford's syntypes. This species has not been recorded from South America, but could occur there in northern areas where appropriate hosts are present.

Scolytus proximus Chapuis

Plate XLI

Scolytus proximus Chapuis, 1980:57. Holotype ♀; Nouvelle Granada; IRSNB, Brussels (References in Wood & Bright c1992:357)

Diagnosis: Male frons more strongly convex, more coarsely punctuated than in *propinquus* Blandford, without any long setae on lateral margins; sternum 2 with a large, laterally compressed spine, setae include both palmate and simple setae.

Male: Length 2.5 mm, 1.9 times as long as wide; color dark reddish brown. Frons rather strongly convex, reticulate to vertex, punctures moderately coarse; a moderately large, somewhat dorsoventrally compressed median elevation about midway between epistoma and upper level of eyes; vestiture sparse, hairlike, rather short, longer in lower, lateral areas. Pronotum 1.0 times as long as wide; surface smooth, shining, most punctures on disc appearing very feebly subvulcanate, very small on disc, becoming very coarse toward anterior and lateral margins; glabrous except for sparse hair at margins. Elytra 1.0 times as long as wide, 1.0 times as long as pronotum; striae feebly impressed on posterior half, punctures rather small, distinct; interstriae three times as wide as striae, weakly impressed on posterior half, punctures slightly smaller than those of striae, smooth, shining; vestiture of rather stout, suberect bristles on posterior half of interstriae 1–3, one or two setae on 4–9, with two or three additional setae on 5 and 7. Sternum 2 subvertical, somewhat convex, a large, laterally compressed spine at anterior margin, punctures rather coarse, with two kinds of setae, 60 percent plumose, about 40 percent stout bristles of moderate length, sterna 3–5 with only bristles.

Distribution: Colombia to Venezuela.

Colombia: "Nouvelle Grenada."

Venezuela: 9 km S Barrancas, Barinas, 1-X-1969, 150 m, No. 31, "Haevea," SLW.

Hosts: Apparently *Lonchocarpus* sp., identified by a local campesino as "haevea."

Notes: One male was walking on the outer bark of a log 30 in cm diameter. That male I compared directly to the holotype.

Scolytus torulus Wood

Scolytus torulus Wood, 1975:25. Holotype ♂; Rincon de Osa, Puntarenas, Costa Rica; USNM, Washington (References in Wood & Bright c1992:378)

Diagnosis: See description.

Male: Length 2.0–2.4 mm, 2.0 times as long as wide; color dark reddish brown. Frons about as in *proximus* Chapuis except shining above upper level of eyes, tubercle slightly smaller, punctures smaller, setae on upper half much longer, slightly more numerous. Pronotum about as in *proximus* except punctures on disc not at all subvulcanate. Elytra about as in *proximus* except setae almost absent from interstriae 2. Sternum 2 without any palmately divided setae, median spine much smaller.

Female: Similar to male except frontal tubercle absent, setae on lateral and dorsal margins much more abundant, longer; median spine on sternum 2 half as large as in male, all setae simple (no palmately divided setae). It is entirely possible that my "female" is a male that lacks a frontal tubercle and has longer than normal setae (for a male).

Distribution: Costa Rica: Rincon, Osa Peninsula, 11-VIII-1966, 30 m, No. 72, legume tree.

Hosts: Leguminosae tree (presumably *Lonchocarpus* sp.), 30 cm in diameter.

Notes: The above treatment was based on the type series of 11 specimens.

Scolytus marginatus Chapuis

Scolytus marginatus Chapuis, 1869:56. Holotype ♀; Yucatan, Mexico; IRSNB, Brussels (References in Wood & Bright c1992:344)
Scolytus productus Hagedorn, 1905:547. Holotype ♂; San Esteban, Venezuela; MNHN, Paris

Diagnosis: See description.

Male: Length 2.5 mm, 2.1 times as long as wide; color dark reddish brown. Frons more strongly convex than males of allied species; tubercle not as high, dorsoventrally compressed, weaker than in *laetus* Wood; punctures coarser; reticulation near epistoma and above upper level of eyes reduced, smooth, shining; setae short, sparse (even less than in *proximus* Chapuis). Pronotum and elytra about as in allied species. Sternum 2 spine not laterally compressed, rather long, pointed; surface dull on 2–5 (largely covered by an incrustation), setae simple, fine, hairlike, rather short.

Distribution: Mexico: Yucatan, Deyr.

Notes: The above treatment was based on the holotype of *marginatus* Chapuis. The holotypes of *proximus*, *torulus* Wood, *laetus* Wood, and *marginatus* were all compared directly to one another for these notes. It is probable that *productus* Hagedorn (not seen) is a synonym of *proximus*, rather than of *marginatus*.

Scolytus laetus Wood

Scolytus laetus Wood, 1975:25. Holotype ♂; 48 km N Rosamorada, Nayarit, Mexico; USNM, Washington (References in Wood & Bright c1992:339)

Diagnosis: See description below.

Male: Length 2.4–2.5 mm, 2.2 times as long as wide; color dark reddish brown. Frons similar to *torulus* Wood except less strongly convex, frontal tubercle lower, more

dorsoventrally compressed, setae on lateral margin coarser; longer. Pronotum about as in *torulus* except punctures distinctly larger. Elytra as in *torulus* except striae and interstriae punctures slightly larger. Sternum 2 with median spine larger; its dorsal, apical angle more prominent.

Female: Distinguished from female *torulus* by lateral setae on lower half of frons much longer and more abundant, those on dorsal margin very sparse, shorter; sternum 2 unarmed.

Distribution: Mexico: Nayarit, 30 km N Rosamorada, 15-VII-1965, 100 m, No. 251, *Inga paterno*, SLW.

Notes: The above treatment was based on the type series of 5 specimens.

Scolytus peruensis Schedl

Scolytus peruensis Schedl, 1937:157, 160. Lectotype ♂; Rio Toro, La Merdet Chanchamayo, Peru; NHMW, Wien, designated by Schedl 1979:192 (References in Wood & Bright c1992:356)

Diagnosis: Distinguished from *barinensis* Wood by the less definite central tubercle on the male frons; by the much more abundant vestiture on the male frons; by the more finely punctured pronotum; and by the very different sculpture of the elytra.

Male: Length 3.2–3.4 mm, 1.9 times as long as wide; color dark reddish brown, pronotum almost black. Frons on upper two-thirds to vertex obscurely subaciculate, small punctures in rows mostly confluent, elevations between rows of punctures irregular, not forming continuous costae; central tubercles much less definite than in *barinensis*; a moderate, transverse impression immediately above epistoma, punctation in impressed area continued from above, but much smaller, not as deep; vestiture hairlike, fine, sparse, short in central area, moderately abundant, longer on sides to upper level of eyes, dense, darker and much longer on dorsal margin. Pronotum 1.0 times as long as wide; sides almost straight and parallel on basal half, arcuately converging toward broadly rounded anterior margin; surface smooth, shining, punctures on disc minute, becoming 4 or more times larger at anterior margin, larger in lateral areas; glabrous except sparse setae at margins. Elytra 0.90 times as long as wide, 0.90 times as long as pronotum; striae weakly impressed, punctures small, distinctly impressed; interstriae almost four times as wide as striae, smooth, shining, punctures mostly minute, less than half as large as those of striae, some on apical fourth as large as those of striae; declivital slope on apical fourth much weaker than in *barinensis*; vestiture of very sparse interstitial hair on apical fourth. Sternum 2 subvertical, junction with 1 abrupt, median spine occupying middle half of segment length (not attaining anterior margin or posterior margin), laterally compressed, length on type appearing altered by sibling chewing; surface of 2–5 dull, punctures on 3–5 very small, moderately close; vestiture entirely abraded on type.

Female: Similar to male except pseudoaciculation on frons weaker; vestiture much less abundant, especially above eyes; median spine on sternum 2 longer than wide, its apex narrowly rounded; setae on 2–5 of very short, stout, almost scalelike hair.

Distribution: Peru: Rio Toro, La Merced on Rio Chanchamayo (32 mi. NE Tarma).

Notes: The above treatment was based on the male holotype and female allotype from Peru.

Scolytus barinensis Wood

Plate XXXVI

Scolytus barinensis Wood, 1971:18. Holotype ♂; Campamento Cachicamo, 40 km E Canton, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:325)

Diagnosis: Male frons closely aciculate to median line, a rather small, median tubercle at middle; male sternum 2 armed on anterior two-thirds by a strongly compressed carina (about half as high as its basal length); female frontal tubercle almost obsolete, carina on sternum 2 similar but smaller than in male.

Male: Length 2.0–2.9 mm, 1.7 times as long as wide; color very dark reddish brown, pronotum black. Frons shining, transversely, modestly impressed on lower third, weakly convex and moderately aciculate above to median line, a moderate, subconical, median tubercle at center of area below upper level of eyes; lower third finely, closely tuberculate except on epistomal margin; vestiture mostly below upper level of eyes, of moderately abundant, fine, long hair, longer on lateral margins. Pronotum 1.0 times as long as wide; surface smooth, shining, punctures moderately coarse on disc, deep, spaced by about 1–3 diameters of a puncture, slightly larger in lateral areas; glabrous except for a few hairlike setae near anterior margin. Elytra 0.82 times as long as wide, 0.82 times as long as pronotum; striae distinctly impressed at base, more strongly toward apex, punctures rather small, strongly impressed; interstitial punctures at least two-thirds as large as those of striae, interstitial rows feebly impressed at base, almost as deep as those of striae at apex. Declivity modest; posterior margin smooth. Vestiture hairlike, confined to declivity on odd-numbered interstriae. Sternum 2 vertical, dull; anterior two-thirds armed by a strong median carina, its crest longitudinally convex, about half as high as longitudinal length; vestiture of moderately long, coarse hair.

Female: Similar to male except frontal tubercle much smaller to obsolete, vestiture shorter, less numerous; carina on sternum 2 distinctly smaller.

Distribution: Venezuela: 40 km E Canton, Barinas, 8-III-1970, 70 m, No. 356, 381, "Hevecito" (?*Lonchocarpus* sp.), SLW.

Biology: Parent galleries were biramous and transverse. Two females were associated with each male in a gallery system.

Notes: The above treatment was based on the type series of 99 specimens.

Scolytus carinatus Chapuis

Scolytus carinatus Chapuis, 1869:55. Lectotype ♂; Cartagena, Bolivar, Colombia; IRSNB, Brussels, present designation (References in Wood & Bright c1992:325)

Scolytus atratus Chapuis, 1869:58. Holotype ♂; Colombia; IRSNB, Brussels, present limitation (Wood & Bright c1992:324). *New synonymy*

Diagnosis: Distinguished from *barinensis* Wood by the near absence of frontal aciculation, median tubercle smaller, setae above eyes in male dense, reddish brown; spine on male sternum 2 straight, on its apical margin, both apical angles abrupt.

Male: Length 2.8–3.3 mm, 1.9 times as long as wide; color dark reddish brown, pronotum almost black. Frons weakly convex; tubercle about as in *barinensis*; upper area rather finely, closely punctured to median line, aciculation obscure to absent; surface in transverse impression on lower third somewhat granular; tubercles not evident; setae on margin above eyes reddish brown, dense, very long; setae below upper level of eyes similar to *barinensis*. Pronotum as in *barinensis* except punctures on disc slightly smaller. Elytra as in *barinensis* except both striae and interstriae punctures distinctly smaller. Sternum 2 as in *barinensis* except median spine longer (laterally more strongly compressed), its apical margin straight, both anterior and posterior apical angles abrupt (posterior angle subacute).

Female: See notes below; this female could be a species different from male. Similar to male except frons reticulate, punctures sparse, fine, median tubercle replaced low callus; frontal vestiture very sparse, short, none above upper level of eyes; striae punctures feebly impressed, interstriae not impressed, punctures minute; sternum 2 with spine chewed by siblings, only base still present.

Distribution: Colombia: Cartagena [Bolivar], Dejean.

Notes: Although 2 males are cited by Chapuis in the original description, only 1 is now present under this name in his collection. This male is here designated as the lectotype of *carinatus* Chapuis. The second male (from Colombia) now bears the “Chapuis” (?) identification tag of *atratus* Chapuis and is placed as the first of 2 specimens in the *atratus* series. The female holotype of *atratus*, that was the basis for the description, is incorrectly now placed as the second specimen of *atratus*. There is some doubt that the female of *atratus* is of the same species as the 2 males of *carinatus*, even though she bears the locality data of the lectotype of *carinatus*. Although listed above as synonyms in order to call attention to this problem, more material is needed to properly resolve this problem.

Scolytus novateutonicus Schedl

Plate XL

Scolytus novateutonicus Schedl, 1937:162. Syntypes ♂ ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, and Plaumann and Strohmeier (DEI, Munchenberg) Collections (Wood & Bright c1992:355)

Diagnosis: Median elevation on frons of both sexes a low, laterally compressed carina on middle one-third; setae on frons mostly below upper level of eyes in both sexes; male spine on abdominal sternum 2 a simple sword.

Male: Length 3.6–4.3 mm, 1.9 times as long as wide; color dark reddish brown, pronotum almost black. Frons weakly convex; middle third on median line with a rather low, laterally compressed carina, median line above carina smooth, impunctate on median one-seventh, lateral areas rather coarsely aciculate; lateral areas on lower third somewhat aciculate-granulate; vestiture of fine, long, moderately abundant hair from epistoma to upper level of eyes, longer on lateral margins, similar but rather sparse above eyes. Pronotum 1.0 times as long as wide; surface smooth, shining, punctures on disc minute, distinctly larger laterally and near anterior margin; a few hairlike setae near anterior margin. Elytra about 1.0 times as long as wide, 1.0 times as long as pronotum; striae weakly to not impressed, punctures small; interstriae about three times as wide as striae, punctures about one-half to two-thirds as large as those of striae, a few rows weakly impressed on posterior half. Declivity rather weak, posterior margin smooth. Vestiture of stout hair on posterior half of odd-numbered interstriae except near apical margin. Sternum 2 vertical; median spine (its base on anterior one-third) large, swordlike, modestly, laterally compressed, tapered to blunt apex, its dorsoapical angle subacute; vestiture of fine long hair; setae on sternum 5 short, rather abundant near apical margin.

Female: Similar to male except frontal carina and aciculation finer; frontal setae shorter but more numerous; spine on sternum 2 about one-third as large (apex more nearly pointed).

Distribution: Argentina to Brazil.

Argentina: Juto, Jujuy, 14-III-1957, F. Monros; Tabillas, Salta, G.L. Harrington.

Brazil: Nova Teutonia, Santa Catarina.

Notes: The above treatment was based on 3 males and 2 females from Argentina. Two of the males were compared by me directly to Schedl's male syntypes at the NHMW, Wien.

Scolytus submarginatus Schedl

Plate XLII

Scolytus submarginatus Schedl, 1937:163. Syntypes, sex?; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, Plaumann, and Strohmeier (DEI, Munchenberg) Collections (References in Wood & Bright c1992:377)

Diagnosis: Distinguished from *novateutonicus* Schedl by the much stronger brush of hair on the frons above the upper level of the eyes; by the stronger male frontal tubercle that is larger and obscurely, dorsoventrally compressed, with the impunctate area above the tubercle much larger; and by the smaller average size.

Male: Length 2.5–4.0 mm, 2.0 times as long as wide; color rather dark reddish brown, pronotum darker. Frons convex except transversely impressed on lower one-fourth; finely, closely, subacutely punctured, moderately large tubercle near center weakly, dorsoventrally compressed, median one-fourth above tubercle smooth, impunctate from tubercle to vertex; vestiture mostly on lateral margins, long, rather abundant, at least half of setae above upper level of eyes. Pronotum 1.03 times as long as wide; surface smooth, shining, punctures small on disc, distinctly larger near anterior margin, twice as large near lateral margins, glabrous except a few hair-like setae in lateral areas on anterior third. Elytra 1.03 times as long as wide, 1.0 times as long as pronotum; striae feebly to not at all impressed, punctures small, distinctly impressed; interstriae three to four times as wide as striae, smooth, shining, punctures very small (half as large as those of striae), in uniseriate rows (rows not at all impressed, including declivity); odd-numbered interstriae on posterior half with rows of suberect hairlike setae. Sternum 2 subvertical with a large, tapered spine on anterior third, its base slightly, laterally compressed.

Female: Similar to male except frontal tubercles absent, dorsal margin of vertex with a dense row of long setae, their color dark reddish brown; spine on sternum 2 less than half as large.

Distribution: Brazil to Paraguay.

Brazil: Rondon, Parana, 24°38'S, 54°07'W, 500 m, F. Plaumann; Nova Teutonia, Santa Catarina, 20-V-1935, IV-1947, XI-1956, 300–500 m, F. Plaumann.

Paraguay: (Cited in Wood & Bright c1992:337).

Notes: The above treatment was based on 27 specimens from Brazil, 1 male of which I compared to Schedl's male syntypes of *submarginatus*. In 2 females from Nova Teutonia (1935) the female brush of upper setae on the vertex is absent, although the impressions for their insertion are present.

Scolytus obscuriceps Wood, n. sp.

Plate XL

Scolytus obscuriceps Wood: Holotype ♂; Rio Caraguata, Brazil, 24°48'B, 52°27'W, 400 m; DEI, Muncheberg, designated below

Diagnosis: Distinguished from *submarginatus* Schedl by the smaller size; by the much stronger, dorsoventrally compressed median elevation of the male frons, with upper area much more broadly impressed and impunctate on at least median half, lower frons more strongly, more broadly impressed; striae and interstriae punctures slightly larger; spine on sternum smaller (two-thirds as large as in *submarginatus*).

Male: Length 3.4–3.6 mm, 2.0 times as long as wide; color almost black. Frons with a strong dorsoventrally compressed elevation on median third of length of frons below upper level of eyes, this elevation resembling a crest (rather than a tubercle); upper surface flattened and impunctate on slightly more than central half

(impunctate area twice as wide as in *submarginatus*); vestiture resembling *submarginatus* except number of setae on vertex reduced. Pronotum and elytra about as in *submarginatus* except sparse on odd-numbered interstriae, about half as long; spine on sternum 2 similar but half as large as in *submarginatus*.

Distribution: Brazil (Rio Caraguata).

Type material: The male holotype, female allotype, and 3 male paratypes are labeled Brasilien, Rio Caraguata, 24°48'B, 52°27'W, 21-IV-1953, 400 m, F. Plaumann. The holotype, allotype, and 2 paratypes are in the DEI, Muncheberg. One paratype is in the U.S. National Museum.

Brazil (non-types): ESALQ campus, Piracicaba, Sao Paulo, 11-VIII-1973, *Eucalyptus* sp., G.J.M (4 specimens).

Scolytus nodulus (Wichmann)

Scolytus nodulus (Wichmann), 1915:102 (*Eccoptogaster*). Holotype ♀; Petropolis (nordlich von Rio de Janeiro), Brazil; data not given (Synonymy and references in Wood & Bright c1992:355)

Eccoptogaster nodicornis Wichmann, 1915:216. Syntypes, sex?; Brazil: Ypanema; Natterer Collection and NHMW, Wien

Diagnosis: Distinguished from male *submarginatus* Schedl by the much higher frontal tubercle and wider impunctate area above tubercle (more than one-third of distance between eyes); by the more slender spine on sternum 2; and by the larger size.

Male: Length 4.9 mm, 1.8 times as long as wide; color very dark reddish brown. Frons more nearly flat than in *submarginatus*, with central tubercle higher, subacutely elevated, median impunctate area above tubercle much wider (equal to at least one-third distance between eyes). Pronotum about as in *submarginatus*. Elytra similar to *submarginatus* except striae at least moderately impressed, interstriae usually impressed on declivity. Sternum 2 with median spine more slender, not longer. Vestiture on sternum 5 more abundant, more widely distributed.

Distribution: Brazil: Rio de Janeiro; Curitiba, Parana, 28-XI-1937, Claretiano; Ypanema.

Notes: The above treatment was based on one male from Brazil that was compared by me to Schedl's series.

Scolytus dimidiatus Chapuis

Plate XXXIX

Scolytus dimidiatus Chapuis, 1869:57. Lectotype ♀; Toxpan, Veracruz, Mexico; IRSNB, Brussels, present designation (References in Wood & Bright c1992:329)

Diagnosis: Male median frontal elevation dorsoventrally compressed, its transverse length equal to one-sixth of the distance between the eyes, smooth, impunctate area above median elevation equal to more than half distance between the eyes; spine on male abdominal sternum 2 tapered from its base to its apex, usually with a penicillate tuft of hair at its posterior base; female

frons with a dense brush of hair above upper level of eyes.

Male: Length 2.1–3.3 mm, 1.9 times as long as wide, color dark reddish brown. Frons weakly convex above, moderately, transversely impressed on more than lower third; median tubercle dorsoventrally compressed, occupying median one-sixth of area between eyes; impunctate area above tubercle occupying more than median half; lateral areas rather finely punctured, not aciculate; vestiture almost restricted to lateral margins, forming a dense row at margin from epistoma to upper level of eyes, almost glabrous above eyes. Pronotum about as long as wide; surface smooth, shining; punctures on disc fine, distinctly larger near anterior margin, much larger in lateral areas; vestiture restricted to a few hairlike setae on margins on anterior half. Elytra 0.94 times as long as wide, 0.94 times as long as pronotum; striae distinctly, rather weakly impressed, punctures small, distinct; interstriae three to four times as wide as striae, surface smooth, shining, punctures uniseriate, half as large as those of striae, rows not impressed; vestiture restricted to a few setae on posterior half of odd-numbered interstriae. Sternum 2 vertical, median spine at anterior margin large, tapered, with a small tuft of hair at its posterior base.

Female: Similar to male except dorsal margin of frons above eyes with a dense brush of very long, yellowish brown hair, central tubercle absent; spine on sternum 2 much smaller; tuft of hair absent.

Distribution: Mexico (Veracruz) and Cuba to Venezuela.

Venezuela: 40 km E Canton, Barinas, 5-III-1970, 70 m, Nos. 345, 385, 388, *Lonchocarpus margaritensis*, No. 344 from an unidentified liana, SLW.

Hosts: *Lonchocarpus margaritensis*, *L.* spp. and an unidentified, large liana.

Biology: Parental tunnels were biramous and transverse in the cambium area. Two females were usually associated with 1 male in a gallery system.

Notes: The above treatment was based on the 5 male and 3 female syntypes in the Chapuis Collection (he had the sexes reversed), 36 specimens from Mexico and Central America, and 240 specimens from Venezuela. The first specimen in the Chapuis series of syntypes, a female from Toxpam [Veracruz, Mexico], is here designated as the lectotype of *dimidiatus* Chapuis.

Scolytus thoracicus Chapuis

Plate XLIII

Scolytus thoracicus Chapuis, 1869:55. Lectotype ♂; Brazil; IRSNB, Brussels, present designation (Synonymy references in Wood & Bright c1992:378)

Eccoptogaster brevicauda Wichmann, 1915:104. Holotype, sex?; Boa Sorta, Minas Geraes, Brazil; data not given

Diagnosis: Distinguished by the “stepped” median spine on sternum 2 in both sexes; by the strong, transverse elevation on the male frons; and by the convex, finely subaciculate female frons with short, moderately abundant setae.

Male: Length 3.0–4.2 mm, 1.9 times as long as wide; color dark reddish brown, pronotum darker. Frons flattened on dorsal half, rather strongly, transversely impressed on lower third, median tubercle rather strongly, dorsoventrally compressed, transversely subcarinate on median half; upper area smooth, usually dull on more than median half, rather coarsely, closely punctured in lateral areas; vestiture very long, largely restricted to dense rows on lateral margins from near epistoma to slightly above eyes, very sparse on upper margin. Pronotum 1.0 times as long as wide; surface smooth, shining, punctures on disc very small, rather close, slightly larger toward anterior and lateral margins; glabrous except for sparse setae near anterior margin. Elytra 1.0 times as long as wide, 1.0 times as long as pronotum; striae weakly, narrowly impressed, punctures small, spaced by diameter of a puncture; interstriae smooth, shining, three to four times as wide as striae, punctures uniseriate, each half as large as those of striae, some rows weakly impressed near declivity (usually 3, 5). Vestiture almost hairlike, restricted to posterior fourth on 1, 3, and 5, sparse near declivity elsewhere. Sternum 2 vertical, armed by a median, laterally compressed spine on more than anterior half, its posterior two-thirds half as high as its longitudinal base, its anterior one-third conspicuously higher (usually twice as high as posterior area); vestiture of fine, long, moderately abundant hair.

Female: Similar to male except frons convex, tubercle (carina) absent; punctures fine, coarse, rather weakly aciculate; vestiture of fine, uniformly distributed, moderately short hair, extending above upper level of eyes; spine on sternum 2 two-stepped as in male but much smaller.

Distribution: Brazil: “Bresil, Deyr.”; Nova Teutonia, Santa Catarina, 27°11'B, 52°23'L, 14-VIII-1934, IX-1934, XI-1956, F. Plaumann.

Notes: The above treatment was based on the 2 male syntypes in the Chapuis Collection and on 16 specimens from Nova Teutonia. The first male syntype is here designated as the lectotype of *Scolytus thoracicus* Chapuis.

Species Not Seen

Scolytus transversalis Eggers

Scolytus transversalis Eggers, 1943:375. Holotype, sex?; Cochabamba, Bolivia; MNHN, Paris; not found (References in Wood & Bright c1992:378)

TRIBE CTENOPHORINI

Description: Frons sexually dimorphic, male impressed in *Pycnarthrum* and *Gymnochilus*, impression obscure in *Microborus*, male convex and female variously sculptured and ornamented in *Scolytodes*. Eye usually elongate, its anterior margin entire to sinuate. Antennal scape elongate; funicle 5–6-segmented, 7-segmented in *Gymnochilus*; club with or without sutures. Pronotum with anterior slope armed or not, its lateral margins costate; procoxae widely separated. Protibia with 1 or more socketed denticles moderately to usually embedded in cuticle on lateral margin, spine at lateral apical angle usually extending beyond level of tarsal insertion.

Biology: The biology of *Scolytodes* is unusually diverse. The other 3 genera are more similar to one another. All are monogynous, except for a few polygynous *Scolytodes*.

All are phloeophagous, except *Scolytodes multistriatus* is xylophagous and many of the species in *Cecropia* petioles are myelophagous. Parental galleries in *Pycnarthrum* and *Gymnochilus* are transversely biramous; in *Microborus* they are indefinite, largely nondirectional and without a definite pattern. In *Scolytodes* they vary from an indefinite to elongate cave to stellate (in polygynous species). The eggs may be deposited in irregular clusters in the frass of parental galleries or placed in crude niches. Definite niches are formed in *Pycnarthrum* and *Gymnochilus*. The larvae feed communally in some *Scolytodes*; they form individual mines in the other three genera. Except for those species that have been transported abroad through commerce, all members of this tribe are restricted to the American tropics.

Key to the Genera of Ctenophorini
(Adapted from Wood 1986:60)

- | | | |
|-------|--|---------------------------|
| 1. | Eyes elongate, usually approximate above and below, coarsely faceted, shallowly emarginate; entire surface of pronotum smooth and punctured, not armed | 2 |
| — | Eye oval, entire, finely faceted, pronotum asperate on anterior areas or, if smooth, then anterior margin of elytra bearing a fine, raised line | 3 |
| 2(1). | Antennal club subglobular, about as long as wide, sutures not clearly indicated; pronotum longer than wide, its lateral margins straight or feebly constricted; vestiture hairlike, usually sparse; small, slender species; phloeophagous; 1.1–1.5 mm | <i>Microborus</i> |
| — | Antennal club asymmetrically flattened, pointed, at least 1.5 times as long as wide, sutures 1 and 2 clearly marked by setae; pronotum wider than long, its lateral margins arcuate; vestiture of abundant, short, bristlelike scales; larger, stouter species; phloeophagous; 1.3–2.1 mm | <i>Pycnarthrum</i> |
| 3(1). | Antennal funicle 7-segmented, club large, broad, usually with procurved sutures or sutures obsolete; elytral vestiture consisting of abundant, minute hair and sparse interstitial rows of long, erect, scalelike bristles, summit of pronotum on basal third, asperities on anterior area coarse; elytral base without a fine, raised line; phloeophagous; 1.5–2.3 mm | <i>Gymnochilus</i> |
| — | Antennal funicle 5- or 6-segmented, club small, sutures present or not; elytral vestiture (usually) sparse, hairlike; pronotal asperities fine, if present; summit at middle or indefinite; basal margins of elytra marked by a fine, raised line; mostly phloeophagous; 0.9–3.5 mm | <i>Scolytodes</i> |

GENUS *MICROBORUS* BLANDFORD

Microborus Blandford, 1897:175. Type-species: *Microborus boops* Blandford, monobasic (References in Wood & Bright c1992:383–384)
Pseudocrypturgus Eggers, 1919:236. Type-species: *Pseudocrypturgus camerunus* Eggers = *Microborus boops* Blandford, monobasic (Synonymy and references in Wood & Bright c1992:383)

Diagnosis: Antennal club subglobular, sutures not clearly indicated; funicle 6-segmented; vestiture hairlike; body slender.

Description: Body elongate. Frons obscurely dimorphic; antennal scape elongate; funicle 6 segmented, club subglobular, sutures not clearly indicated; vestiture sparse, hairlike; sculpture very conservative.

Distribution: Eight species were reported by Wood & Bright (1992:383–384) of which 4 have been recorded from South America. One species (*boops* Blandford) was transported through commerce to tropical Africa. Wood (1982:452–453) presents a key to 7 of the species. The eighth species, *bicolor* Eggers, is known only from the holotype.

Biology: This genus is unique. The species infest the thick bark of tropical trees in the cork cambium (at the fracture point near the middle of thick outer bark in some tropical trees) where they make long, wandering tunnels. The larvae are comparatively few in number and may not emerge between generations. Apparently more than 1 generation can develop in bark of the same prostrate tree.

Key to the Species of *Microborus*

- 1. Punctures on at least discal interstriae 3 and 4 minute, almost obsolete, very widely spaced; eyes spaced above by 0.82 times width of an eye; vestiture absent except sparse and minute on declivity; tubercles on male declivity small, not larger than in female; French Guyane; 1.3 mm *bicolor* Eggers
- Punctures on discal interstriae closer, more regular; elytral vestiture more abundant, longer; one or more tubercles on male declivital interstriae 2 conspicuously larger than on female 2
- 2(1). Eyes broadly separated above by twice width of an eye; tubercles on male declivital interstriae 2 only slightly enlarged; setae on all declivital interstriae uniseriate, none longer than distance between rows; crest of subapical declivital carina (apex of interstriae 9 to costa) of almost uniform height, only feebly serrate; Venezuela; *Clusia*; 1.4–1.5 mm *lectus* Wood
- Eyes narrowly separated above by half width of an eye; one to four enlarged tubercles on each male declivital interstriae 2; setae (except on a few females) on at least declivital interstriae 2 abundant, confused, most much longer than distance between rows; crest of subapical declivital carina more distinctly serrate 3
- 3(2). Discal striae more strongly impressed, as wide or wider than interstriae; setae on declivital interstriae as long as distance between rows, those on 3 usually uniseriate; crest of subapical declivital carina strongly serrate; Guatemala to Panama, etc.; *Rheedia*, lianas, etc.; 1.2–1.4 mm *boops* Blandford
- Declivital striae feebly impressed, narrower than interstriae; setae on declivital interstriae up to two or more times longer than distance between rows, those on 3 abundant and confused; crest of subapical declivital carina only moderately serrate; Venezuela and Suriname to Brazil; *Clusia*, etc.; 1.3–1.4 mm *aberrans* Wichmann

Microborus bicolor Eggers

Microborus bicolor Eggers, 1933:19. Holotype ; Nouveau Chantier, French Guyane; MNHN, Paris (References in Wood & Bright c1992:383)

Diagnosis: See description.

Female: Length 1.4 mm, 2.6 times as long as wide; color very dark brown, elytra reddish brown. Frons as in *ambitius* Wood except reticulation coarser; eyes separated above by 0.82 times width of an eye. Pronotum 1.22 times as long as wide; stouter than *ambitius*, with

punctures slightly deeper, closer. Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; stouter but outline similar to *ambitius*; disc as in *ambitius* except interstitial punctures smaller, closer. Declivity as in *ambitius* except striae punctures distinctly smaller, interstriae proportionately very slightly wider, granules indistinctly larger; ventrolateral margin much less strongly elevated. Declivital vestiture short as in *ambitius* but very slightly stouter.

Distribution: French Guyane: Bas Carsvenne, 1899, F Geay.

Notes: The above treatment was based on the female holotype of *bicolor* Eggers from notes made by me on 27 June 1972.

Microborus lectus Wood

Plate XLIV

Microborus lectus Wood, 1971:17. Holotype ♂; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:384)

Diagnosis: Eyes separated above by about twice width of an eye; setae on all declivital interstriae uniseriate, none longer than distance between rows; male declivital interstriae 2 with tubercles small.

Male: Length 1.4–1.5 mm, 2.8 times as long as wide; color rather dark reddish brown. Frons moderately convex, a slight elevation just above level of antennal insertion, a weak, transverse impression just above epistoma; surface shining except reticulate at sides and above; punctures sparse, moderately coarse; eyes separated above by twice width of an eye. Pronotum 1.4 times as long as wide; sides weakly constricted, almost straight on basal three-fourths, broadly rounded in front; surface weakly reticulate, punctures rather coarse, deep, close, oval; glabrous. Elytra 1.8 times as long as wide, 1.5 times as long as pronotum; striae rather strongly impressed, punctures coarse, deep, close; interstriae as wide as striae, smooth, shining, rather strongly convex, punctures fine, uniseriate, rather widely spaced. Declivity steep, convex; striae strongly impressed except lower half of 1, punctures strongly reduced, minute on 1; interstriae strongly narrower on left side, moderately so on right, 2 feebly elevated and armed by three to six small teeth (not equal on both sides), 3 and 4 convex, unarmed, continuing to 7, 7 strongly, acutely elevated and continued to apex. Vestiture confined to declivity, of coarse, rather short interstitial hair, a few scales on 1 and 2.

Female: Similar to male except pronotum more finely sculptured; elytral declivity about as on disc except interstitial punctures very finely granulate and punctures on striae 1 much smaller; declivital interstriae 2 only moderately elevated; without any scales on declivity.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 14-X-1969, 2500 m, No. 57, *Clusia*, SLW.

Biology: Most galleries were in the cork cambium fracture-point in thick bark of old, prostrate trees from which other bark beetles had previously emerged. It appeared that more than one generation developed in the same log. Parental galleries were not clearly defined, few larvae developed from each gallery system.

Microborus boops Blandford

Microborus boops Blandford, 1897:175. Holotype ♀; Tamahu, Alta Verapaz, Guatemala; BMNH, London (Synonymy and references in Wood & Bright c1992:383)

Pseudocrypturgus camerunus Eggers, 1919:236. Syntypes, sex?; Kamerun; Hamburg Museum, lost, 1 in NHMW, Wien

Diagnosis: Eyes separated above by one-half diameter of an eye; setae on male declivital interstriae 2 and 3 strongly confused, rather long; discal striae impressed, narrower than interstriae.

Male: Length 1.2–1.4 mm, 2.7 times as long as wide; color dark reddish brown. Frons with eyes separated above by half width of an eye, reticulate and finely, sparsely punctured above, smooth below, with punctures of irregular size; vestiture sparse, hairlike, inconspicuous. Pronotum about as in *lectus* Wood, except surface weakly reticulate, punctures slightly smaller, not as deep. Elytral disc similar to *lectus*, striae punctures slightly smaller, interstriae less strongly convex. Declivity with interstriae 2 distinctly elevated and armed by two to four small denticles (enlarged granules, those on opposite elytron may differ), setae on 2 abundant, confused, on 1–4 little if any longer than distance between rows; no scales.

Female: Similar to male except striae less strongly impressed; declivital interstriae 2 not elevated or armed by tubercles, and setae uniseriate.

Distribution: Guatemala and Jamaica to Panama, introduced to tropical Africa. Not yet recorded from South America, but probably introduced there through commerce.

Hosts: *Clusia*, *Rheedia*, and a large liana.

Biology: As described for *lectus*.

Notes: The above treatment was based on 59 specimens from Jamaica, Guatemala, Honduras, Panama, and Africa. The holotypes of *boops* Blandford and *camerunus* Eggers were examined and compared to my material.

Microborus aberrans Wichmann

Plate XLIV

Microborus aberrans Wichmann, 1914:143. Syntypes, sex?; Nouveau Chantier, French Guyane; Wichmann Collection (?) (Synonymy and references in Wood & Bright c1992:383)

Microborus setulosus Eggers, 1933:19. Holotype, sex?; French Guayane; MNHN, Paris

Microborus inittans Eggers, 1940:131. Holotype ♂; Insel Guadeloupe; USNM, Washington

Diagnosis: Declivital striae weakly impressed, narrower than interstriae; male declivital setae two or more times longer than in *boops* Blandford and strongly confused on both interstriae 2 and 3; crest of subapical carina from interstriae 9 to apex on declivity more finely serrate.

Male: Length 1.3–1.4 mm, 2.8 times as long as wide; color reddish brown, pronotum darker. Frons convex, reticulate, punctures rather coarse, distinctly impressed; vestiture sparse, short, hairlike, inconspicuous; eyes separated above by distance equal to one-half width of an eye. Pronotum about as in *lectus* Wood except surface rather strongly reticulate, punctures slightly smaller, not as deep. Elytra resembling *lectus*, except surface rather strongly reticulate, punctures slightly smaller, not as deep. Elytra resembling *lectus*, striae weakly impressed, more distinctly near declivity, punctures rather small, deep, close; interstriae distinctly wider (one and

GENUS *PYCNARTHURUM* EICHHOFF

one-half times) than striae, smooth, shining, punctures small, uniseriate, almost half as large as those of striae. Declivity steep, convex; interstriae 2 (not elevated) armed by two (variable) moderately large denticles. Vestiture on interstriae 2 and 3 strongly confused, rather abundant, length of fine setae equal to two or more times width of an interstriae.

Female: Similar to male except denticles on declivital interstriae 2 absent, small tubercles on 1–3 about equal; hairlike setae on declivital interstriae 2 and 3 much less abundant, most uniseriate, shorter, few longer than distance between rows.

Distribution: Venezuela and Suriname to Brazil.

Brazil: Bahia, Cepec, Ilheus, 11-III-1981, blacklight, Kaston.

Suriname: “Surinam, 180.”

Venezuela: 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 277, *Clusia*, SLW.

Biology: As described for *lectus*.

Notes: The above treatment was based on 7 specimens from Brazil, 1 from Suriname, and 41 from Venezuela. This species is variable; males often have only one pair of denticles on declivital interstriae 2 and the setae on 2 and 3 may be uniseriate and comparatively short. The holotypes of *aberrans* Wichmann, *imitans* Eggers, and *setulosus* Eggers were examined and compared directly to my series.

Pycnarthrum Eichhoff, 1878:41, 104. Type-species: *Pycnarthrum gracile* Eichhoff = *Hypoborus hispidum* Ferrari, subsequent designation by Hopkins 1914:128 (Synonymy and references in Wood & Bright c1992:384)

Nemobius Chapuis, 1869:41. Type-species: *Nemobius lambottei* Chapuis = *Hypoborus hispidum* Ferrari, subsequent designation by Hopkins 1914:128, preoccupied by Serville 1839

Monebius Hopkins, 1914:125. Type-species: *Nemobius lambottei* Chapuis = *Hypoborus hispidum* Ferrari, automatic, an isotypical junior synonym

Nomebius Novas, 1915:34. Type-species: *Nemobius lambottei* Chapuis = *Hypoborus hispidum* Ferrari, automatic, an isotypical junior synonym

Diagnosis: Male frons feebly to strongly impressed, female convex; antennal funicle 6 segmented, club asymmetrical, with 2 sutures; eyes approximate below, coarsely faceted. Pronotum quadrate, unarmed by asperities, closely punctured; lateral margins costate. Elytra striate, declivity steep, convex, unarmed. Vestiture short, abundant, most somewhat scalelike.

Distribution: Tropical America, including the Galapagos Islands. Wood & Bright (c1992:385–386) list 16 species, 9 of which occur in South America.

Biology: The species are monogynous and phloeophagous. Parental galleries are biramous, transverse, and mostly in the phloem. Eggs are deposited individually in niches. Larval mines wander in the phloem and are comparatively short. Larval mines are commonly dense and may obliterate gallery patterns.

Key to the Species of *Pycnarthrum*

- 1. Male frons feebly to weakly impressed near center on middle third; pronotum shining (anterior third with obscure reticulation in some *hispidum*); declivital interstriae rarely with tubercles 2
- Male frons moderately to strongly, broadly concave from epistoma to near or above upper level of eyes (weak in *kleinei*); pronotum partly to entirely reticulate; ground setae on discal interstriae hairlike (feebly plumose in *carinatus* and *subcarinatus*) 5
- 2(1). Erect interstitial setae slender, almost hairlike, in uniseriate rows; ground setae of fine, short, strial hair and very sparse, similar interstitial hair on both disc and declivity; elytral declivity more strongly, much more narrowly convex; Colombia; *Guarea trichilioides*; 1.7–2.0 mm *fulgidum* Wood
- Erect interstitial setae stout, not hairlike; ground setae stout or plumose at least on declivity; declivity very broadly convex to flattened 3
- 3(2). Erect interstitial setae stout, short, each three to four times as long as wide, equal in length to no more than half distance between rows; setae in ground cover stout, plumose on both disc and declivity; setae on pronotum a mixture of stout and slender; USA (S Texas and S Florida) to Colombia and Guiana; 1.5–2.1 mm *hispidum* (Ferrari)
- Erect interstitial setae more slender, each six to eight times as long as wide, equal in length to two-thirds distance between rows; setae in ground cover hairlike on disc, hairlike to stout or plumose on declivity; setae on pronotum of fine hair; male striae 1 with punctures enlarged and interstriae 1–3 with tubercles 4

CTENOPHORINI

- 4(3). Male discal interstriae 1 and 2 each with a row of tubercles almost to base, 3 with tubercles near and on declivity; declivity moderately flattened, more distinctly arched; interstitial setae stout to subplumose on declivity; Costa Rica to Colombia and Venezuela; *Brosimum*; 1.9–2.2 mm *brosimi* Wood
- Male discal interstriae 1 and 2 each with a row of tubercles almost to base, 3–8 each with a row of tubercles near and on declivity, some of those on 6–8 acutely pointed; declivity rather strongly flattened, with little or no arch; interstitial ground setae hairlike on both disc and declivity; Ecuador; 1.9 mm *tuberculifer* Wood
- 5(1). Striae not impressed, punctures distinct, very small, interstriae about three to five times as wide as striae; ground setae on disc hairlike; declivity more narrowly convex; pronotum reticulate to base 6
- Striae weakly, distinctly impressed, punctures larger, interstriae not more than three times as wide as striae 7
- 6(5). Punctures on pronotum distinctly smaller, vestiture finer, longer; on elytral declivity ground setae at least two-thirds as long as setae in rows of erect bristles and distinctly, more conspicuously subplumose; Galapagos Islands (Pacific); 2.2–2.3 mm *insulare* Blair
- Punctures on pronotum distinctly larger, vestiture coarser; on elytral declivity ground setae half as long as bristles in erect rows, much less conspicuously subplumose; Fernando Noronha Island of Brazil (Atlantic); 1.8 mm *setulosum* Waterhouse
- 7(5). Mature color yellowish brown; striae minutely subgranular, punctures small, indistinct; interstriae less than twice as wide as striae; interstitial setae on disc hairlike; pronotum reticulate to base; Mexico (Jalisco) and Guadalupe Island to Venezuela; *Ficus*; 1.6–1.7 mm *pallidum* (Chapuis)
- Mature color brown to reddish brown; striae never granular, punctures larger, clearly impressed; pronotum partly reticulate, partly shining 8
- 8(7). Male frontal concavity not attaining upper level of eyes, epistoma without an acute, transverse carina on median area; erect setae on discal interstriae slender, ground setae slender (not at all plumose); declivity more narrowly convex 9
- Male concavity on frons attaining upper level of eyes, epistoma armed by an acute, transverse carina on median one-fifth; erect interstitial setae on disc stouter, about half of ground setae obscurely plumose; declivity more broadly convex 11
- 9(8). Body form more slender, 2.3 times as long as wide; setae on pronotum very short, inconspicuous, stoutest setae very slender, others hairlike; interstitial ground cover setae on disc hairlike, setae in erect rows each about twice as long as ground setae on disc and declivity and each about eight times as long as wide; interstitial ground setae on declivity obscurely, weakly plumose; Brazil (Bahia); 1.4–1.7 mm *bahiae* Wood
- Body stouter, 2.0 times as long as wide; setae on pronotum of 2 kinds, both longer, stouter setae about four to six times as long as wide; interstitial ground cover setae on basal half of disc either absent or stout, rows of erect setae evident only on and near declivity, most about four times as long as wide 10
- 10(9). Discal interstriae twice as wide as striae; striae in uniseriate rows from base to apex, interstitial ground setae absent, erect interstitial scales uniseriate to base; Brazil (Para); 1.3 mm *uniseriatum* Schedl
- Discal interstriae three times as wide as striae; striae present, interstitial, interstitial setae on disc including confused hairlike ground setae as well as uniseriate rows of erect scales; Brazil (Mato Grosso); 1.7 mm *kleinei* Eggers

- 11(8). Upper half of male concavity on frons less strongly impressed, carina on epistoma not as strongly elevated; erect interstitial setae on disc and declivity more slender, most at least six times as long as wide; female epistoma with a weak carina similar to male; Venezuela; *Brosimum*; 1.6–2.0 mm
 *subcarinatum* Wood
- Upper half of male concavity on frons much more strongly impressed, carina on epistoma distinctly higher; erect interstitial setae on disc and declivity stouter (some four times as long as wide); female not seen; Bolivia to Peru; 1.9–2.0 mm *carinatum* Wood

Pycnarthrum fulgidum Wood

Pycnarthrum fulgidum Wood, 1977:217. Holotype; Carton de Colombia forest 8 km S Colonia, Valle de Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:384)

Diagnosis: Distinguished by the feebly impressed male frons; by the narrowly convex elytral declivity; by the absence of interstitial ground setae on the elytra (strial setae are present); and by the smooth, shining surfaces of pronotum and elytra.

Male: Length 1.7–2.0 mm, 2.1 times as long as wide; color pale brown, elytra yellowish brown. Frons convex on upper third, shallowly, weakly impressed on central third, somewhat flattened toward epistoma, epistomal lobe conspicuous; surface shining below, weakly reticulate above; punctures small, shallow, moderately close; vestiture sparse, rather short, moderately coarse, inconspicuous; eyes separated above by twice width of an eye. Pronotum 0.90 times as long as wide; surface smooth, shining, punctures small, deep, moderately close, spaced by about one to two diameters of a puncture; vestiture of fine, short, inconspicuous hair. Elytra 1.3 times as long as wide, 1.6 times as long as pronotum; basal margin a continuous costa; striae not impressed, punctures small, shallow, spaced within a row by diameter of a puncture; interstriae about four times as wide as striae, smooth, shining, minute setiferous punctures uniseriate (no other punctures or setae present). Declivity rather narrowly convex, steep, moderately arched; sculpture as on disc except strial punctures slightly larger, more distinctly impressed. Strial setae of uniseriate rows of very fine, moderately long hair; interstitial setae uniseriate on disc and declivity, slender, each about two-thirds as long as distance between rows, spaced within a row by length of a seta.

Female: Similar to male except frons more extensively convex, its central impression less extensive, weaker; discal interstriae 3 and 4 each with up to ten interstitial ground hairs.

Distribution: Colombia: 8 km S Cononia, Valle de Cauca (Carton de Colombia woodland), 9-VII-1970, No. 650, *Guarea trichilioides*, SLW.

Biology: Parental tunnels were made in a broken log about 15 cm in diameter. Parental galleries were biramous and were primarily in the phloem.

Notes: The above treatment was based on the type series of 6 whole and 4 broken specimens.

Pycnarthrum hispidum (Ferrari)

Plate XLV

Pycnarthrum hispidum (Ferrari), 1867:19 (?*Hypoborus*). Holotype, sex?; Cuba; NHMW, Wien, lost from pin (Synonymy and references in Wood & Bright c1992:384–385)

Nemobius lambottei Chapuis, 1869:42. Lectotype ♀; Teapa, Mexico, IRSNB, Brussels, designated by Wood 1973:183

Pycnarthrum gracilis Eichhoff, 1878:104. Lectotype ♂; Cuba insula Americana; USNM, Washington, designated by Wood 1973:183

Pycnarthrum quadraticolle Eichhoff, 1878:106. Lectotype ♂; Mexico; USNM, Washington, designated by Wood 1973:183

Pycnarthrum transversum Blandford, 1897:177. Lectotype ♀; Mirandilla, Guatemala; BMNH, London, designated by Wood 1973:183

Pycnarthrum reimoseri Schedl, 1934:208. Syntypes ♀; Jimenez on Osa Peninsula, and Volcan Irazu, Costa Rica; NHMW, Wien

Diagnosis: Male frons very weakly impressed, not truly concave; erect interstitial setae less than half as long as distance between rows; setae in ground cover plumose on both disc and declivity.

Male: Length 1.5–2.1 mm, 2.2 times as long as wide; color brown, elytra usually lighter. Frons somewhat flattened from epistoma to upper level of eyes, shallowly, subconcavely impressed on median half of middle third of this area; frons strongly reticulate above, weakly below, punctures small, shallow, rather close; vestiture coarse, moderately abundant, short, about uniformly distributed. Pronotum 0.94 times as long as wide; surface smooth, shining except reticulate on anterior fourth, punctures rather small, close, deep; vestiture rather abundant, short, a mixture of fine hair and stout setae of about equal abundance. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; basal margin undulating, somewhat subcrenulate; striae feebly impressed, punctures rather coarse, close, deep; interstriae about 1.5 times as wide as striae, smooth, shining, punctures minute, rather numerous, confused. Declivity steep, broadly convex, somewhat flattened; interstriae narrower than on disc; sculpture similar. Vestiture of interstitial rows of erect setae, each about four times as long as wide, half as long as distance between rows, spaced within a row by less than length of a seta; ground cover of small setae of moderate abundance, subplumose on both disc and declivity (plumose filaments obscure in some specimens).

Female: Similar to male except frons more strongly convex and without a central impression.

Distribution: Mexico (Jalisco), S Texas, and S Florida to Venezuela and Guiana.

Guiana: Cited in Wood & Bright c1992:384).

Venezuela: 5 km W El Pino, Zulia, 20-X-1969, 10 m, No. 141, at light, SLW.

Hosts: *Ficus* spp.

Biology: Parent galleries were biramous, transverse, and almost entirely in the phloem. Larval mines wandered aimlessly and usually obliterated parent mines. It is very abundant within its range and is commonly attracted to light.

Notes: The above treatment was based on 90 specimens from the USA, Mexico, and Central America (Wood 1982:459) and on 1 from Venezuela.

Pycnarthrum brosimi Wood

Plate XLV

Pycnarthrum brosimi Wood, 1971:14. Holotype ♂; 9 km S Barancas, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:384)

Diagnosis: Distinguished from *fulgidum* Wood by the total absence of a male frontal impression; by the eyes being separated above by less than the diameter of an eye; and by the broadly convex elytral declivity, with interstriae 1–4 each with a row of fine tubercles.

Male: Length 1.9–2.2 mm, 2.2 times as long as wide; color rather dark reddish brown. Frons with eyes separated by 0.82 times width of an eye; weakly convex from epistoma to upper level of eyes, a weak, almost foveate impression on central one-sixth; surface shining, almost smooth below, becoming reticulate above, punctures very small, distinct, moderately close; vestiture of sparse, rather coarse hair, mostly on lateral margins; eyes very coarsely faceted. Pronotum 0.94 times as long as wide; surface smooth, shining, punctures small, deep, spaced by half to full diameter of a puncture; vestiture on posterior half obsolete to minute hair, margins and anterior area with sparse, coarse hair (tips flattened on some setae). Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; costa at basal margin low, undulating; striae not impressed, punctures on 1 very coarse, very deep, 2 moderately coarse, deep, 3–9 small, moderately deep; interstriae smooth, shining, almost flat, 1, 2, and posterior half of 3 each with a uniseriate row of small tubercles, punctures on 3–9 in uniseriate rows. Declivity moderately steep, very broadly convex; punctures on striae 1 and 2 coarse, about twice as large as punctures on lateral striae; interstriae 1 to 4 each with a row of fine tubercles. Vestiture of interstitial rows of erect bristles, those on declivity moderately flattened; moderately sparse interstitial ground setae (subplumose slender scales) mostly on declivity.

Female: Similar to male except frons much more strongly convex from epistoma to vertex, central concavity absent; punctures on discal striae 1 smaller, almost equal to those on 2; declivity more strongly convex, tubercles on interstriae 1–4 greatly reduced.

Distribution: Costa Rica to Colombia and Venezuela.

Colombia: Carton de Colombia forest 8 km S Colonia, Valle de Cauca, 9-VII-1970, 30 m, No. 645, "Ceibo"

(probably error in identification by Carton de Colombia forester), SLW.

Venezuela: 9 km S Barancas, Barinas, 5-XI-1969, 150 m, No. 106, 1-X-1969, No. 22, *Brosimum*, SLW.

Biology: Parent adults were taken from large limbs and boles of felled or broken trees.

Notes: The above treatment was based on the type series of 24 specimens from Venezuela, 31 from Colombia, and 6 from Costa Rica.

Pycnarthrum tuberculiferum Wood, n. sp.

Pycnarthrum tuberculiferum Wood: Holotype ♂; Pichincha, Puerto Quito, Ecuador; USNM, Washington, designated below

Diagnosis: Distinguished by the rather strongly impressed declivity; and by the presence of pointed tubercles on declivital interstriae 1–8, those on 1–3 extend almost to base on disc. Closely allied to *brosimi* Wood.

Male: Length 1.9 mm, 2.2 times as long as wide; color reddish brown. Frons weakly convex from epistoma to upper level of eyes, a weak median (longitudinal) impression on less than middle third; surface mostly shining below, obscurely reticulate above, punctures small, shallow, not close; vestiture hairlike, rather short, sparse, uniformly distributed; eyes separated above by slightly less than width of eye. Pronotum 0.93 times as long as wide; surface smooth, shining, punctures very small, close; vestiture rather short, hairlike, of moderate abundance. Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; basal margins weakly crenulate; striae 1 moderately, others not impressed, punctures on 1 larger and deeper near and on declivity; interstriae smooth, shining, punctures minute, confused, 1 and 2 each with a uniseriate row of tubercles to base, 3–8 with tubercles near and on declivity, those on 6–8 pointed. Declivity occupying posterior two-fifths of elytral length, gradual, strongly sulcate between interstriae 4. Vestiture of fine, short, hairlike ground setae on disc and declivity; and uniseriate rows of erect setae, almost twice as long as ground setae, each six to eight times as long as wide (shorter and very slender on lower declivity), each about two thirds as long as distance between rows on 1 to 3, one-half as long in lateral areas.

Distribution: Ecuador.

Type material: The male holotype was taken at Pichincha, Puerto Quito, Ecuador, II-1983, G. Onore. The holotype is in the U.S. National Museum, Washington.

Pycnarthrum insulare Blair

Pycnarthrum insulare Blair, 1933:487. Syntypes, sex?; Albermarle Id., Tagus Cove, 200 ft., and Charles Id. sea level, Tower Id., and Hood Id. Galapagos Islands; CAS, San Francisco (References in Wood & Bright c1992:385)

Diagnosis: Distinguished by the concave male frons; by the very small striae punctures; by the narrowly, rather strongly convex elytral declivity; and by the hairlike setae on pronotum and elytra.

Male: Length 2.2–2.3 mm, 2.3 times as long as wide; color yellowish brown. Frons broadly, moderately concave from epistoma to upper level of eyes; surface reticulate, punctures minute, of moderate abundance; vestiture of moderate abundance in central area, slightly more abundant and longer on lateral margins. Pronotum 0.95 times as long as wide; surface reticulate to base, punctures very small, shallow, moderately abundant; vestiture short, of moderately slender hair, rather abundant. Elytra 1.4 times as long as wide; 1.9 times as long as pronotum; basal margins with a row of very weak crenulations; striae feebly impressed, punctures very small, rather deep; interstriae four to five times as wide as striae, almost smooth (obscurely reticulate), punctures very small, moderately numerous, confused. Declivity rather narrowly convex and moderately arched, steep; striae more distinctly impressed; surfaces shining. Erect setae obscure, slightly longer and similar to ground setae, slender, moderately abundant, each about equal in length to one-half to two thirds width of an interstriae, each very obscurely plumose; striae hair present.

Female: Similar to male except frons convex, a very small, weak, median impression; erect interstitial setae more clearly evident on and near declivity.

Distribution: Galapagos Islands: Albermarle Island, Tagus Cove, 200 ft.; Charles Island, sea level; Hood Island; Tower Island, 14-16-IX-1906, F.X. Williams.

Hosts: Although the host was not recorded, allied species infest *Ficus* and *Brosimum*, both in Moraceae.

Notes: The above treatment was based on 1 male and 1 female that were compared by me to part of the original series of *insulare* Blair.

Pycnarthrum setulosum Waterhouse

Pycnarthrum setulosum Waterhouse, 1890:553. Lectotype ♂; Fernando [de] Noronha Island, Brazil; BMNH, London, present designation (References in Wood & Bright c1992:386)

Diagnosis: Distinguished from *insulare* Blair by the smaller size; by the distinctly larger punctures on the pronotum, with coarser, longer vestiture; and by the much shorter, less plumose ground cover setae on the elytral declivity. It is very closely allied to *insulare* but is definitely distinct.

Male: Length 1.8 mm (female 1.8 mm), 2.25 times as long as wide; color light brown. Frons broadly, rather deeply concave from epistoma to upper level of eyes (concealed above by pronotum), surface subshining, weakly reticulate; vestiture sparse, rather coarse, short; eyes separated above by very slightly more than twice width of an eye. Pronotum 0.96 times as long as wide; surface reticulate to base (weak behind summit); punctures distinctly larger and deeper than in *insulare*; vestiture shorter, coarser, less abundant than in *insulare*. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae impressed, punctures small, close, distinctly impressed; interstriae about three to five times as wide as striae, surface smooth, shining, punctures

minute, moderately abundant, confused. Declivity confined to posterior fourth, somewhat narrowly convex, rather steep; striae 1 and 2 distinctly impressed, their punctures deeper. Vestiture of ground cover of short setae (hairlike on disc, feebly subplumose on declivity), and erect, uniseriate rows of rather stout setae (each twice as long as ground cover), each about two-thirds as long as distance between rows, separated within a row by length of a seta, each perhaps 8–10 times as long as wide.

Female: Similar to male except frons rather strongly, somewhat irregularly convex from epistoma to vertex (a few minute granules present).

Distribution: Brazil: Fernando [de] Noronha Island (Atlantic), 88–17.

Hosts: An endemic *Ficus* sp.

Notes: The first pin in the type series bears a male on the right, a female on the left side of the microcard, using the pin perforation nearest the observer as a reference point. This male syntype is here designated as the lectotype of *Pycnarthrum setulosum* Blair. The female syntype is designated as the lectoallotype.

Pycnarthrum pallidum (Chapuis)

Plate XLVI

Pycnarthrum pallidum (Chapuis), 1869:41 (Nemobius). Syntypes 2♂; Guadeloupe; IRSNB, Brussels (References in Wood & Bright c1992:385)

Pycnarthrum reticulatum Schedl, 1940:335. Lectotype ♀; Tonala, Chiapas, Mexico; NHMW, Wien, designated by Wood 1974:287 (References in Wood & Bright c1992:385). *New synonymy*
Pycnarthrum fici Wood, 1971:11. Holotype ♂; Olanchito, Honduras; USNM, Washington

Diagnosis: Distinguished by the strongly concave male frons; by the yellowish brown mature color; by the granular striae; and by the reticulate pronotum.

Male: Length 1.6–1.7 mm, 2.3 times as long as wide; color yellowish brown. Frons broadly, strongly concave from epistoma to upper level of eyes; surface reticulate, punctures minute; vestiture short, uniformly distributed throughout concave area; eyes separated above by almost twice width of an eye. Pronotum 0.96 times as long as wide; surface reticulate to base, punctures small, shallow, close; vestiture short, hairlike, moderately abundant. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; basal margins with a row of minute, obscure crenulations; striae weakly impressed, minutely rugose in most specimens, punctures rather small, not clearly impressed; interstriae slightly wider than striae, almost shining to obscurely reticulate, punctures minute, confused. Declivity broadly convex, rather steep; striae more strongly impressed than on disc, interstriae slightly narrower, more distinctly impressed. Vestiture of ground cover of rather abundant, short, confused, stout setae (almost hairlike); and uniseriate rows of erect setae, each seta stout (sometimes almost scalelike), varying from two to about six times as long as wide, length varying from one-third to one-half distance between rows, spaced within a row by length of a seta

(length of erect setae appears to vary within series, even with setae on an individual).

Female: Similar to male except frons broadly convex from epistoma to vertex.

Distribution: Mexico (Jalisco), Jamaica, and Guadeloupe Island to Venezuela.

Venezuela: 5 km W El Pino, Zulia, 20-X-1969, 10 m, No. 143, *Ficus*, SLW; 50 km W El Pino, Merida, 11-XII-1969, 10 m, No. 193, SLW.

Biology: Limbs and boles of felled, broken, and unthrifty trees were attacked. The parental galleries were biramous and transverse. Larval mines were short and wandered indiscriminantly. They were very abundant.

Notes: The above treatment was based on the 2 male syntypes of *Nemobium pallidus* Chapuis in the Chapuis Collection, on 47 specimens from Mexico and Central America (including the type series of *Pycnarthrum fici* Wood, and the female lectotype of *reticulatum* Schedl), and on 103 specimens from Venezuela.

Pycnarthrum kleinei Eggers

Pycnarthrum kleinei Eggers, 1951:151. Lectotype ♂; Corumba, Mato Grosso, Brazil; USNM, Washington, designated by Anderson & Anderson 1971:17 (References in Wood & Bright c1992:385)

Diagnosis: Distinguished from *bahiae* Wood by the stouter body form; by the much stouter setae on both pronotum and elytra; and by the darker color.

Female: Length 1.7 mm, 2.0 times as long as wide; color dark brown. Frons convex except narrow median line shallowly impressed near center; surface strongly reticulate, punctures very small, shallow; vestiture rather coarse, moderately long, uniformly distributed from epistoma to upper level of eyes. Pronotum 0.90 times as long as wide; surface smooth, shining, except reticulate on anterior one-fifth, punctures small, close, deep; vestiture moderately abundant, a mixture of stout and moderately slender, rather short setae. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; transverse costa at base of elytra undulating; striae on disc not impressed; interstriae three times as wide as striae, smooth, shining, small punctures confused, rather abundant. Declivity rather broadly convex, arch moderately convex, steep; striae weakly impressed, interstriae narrower than on disc. Vestiture on disc of minute strial hair and erect interstitial, uniseriate rows of setae not evident until near declivity; each seta on disc stout, about four to six times as long as wide; on declivity some setae shorter, forming an obscure ground cover, those in erect rows slightly longer.

Distribution: Brazil: Corumba in Mato Grosso.

Notes: The above treatment was based on 1 male and 11 females bearing the label "*Pycnarthrum similis* Egg., det. Egg.," a manuscript name. Schedl (1979:127) cites it as a synonym of *kleinei*; his series appears to have come from the Eggers Collection and probably is part of the same series as the type.

Pycnarthrum uniseriatum Schedl

Plate XLVII

Pycnarthrum uniseriatum Schedl, 1973:370. Holotype ♀; Faz. Taparinha, prox. Santarem, Para, Brazil; NHMW, Wien (References in Wood & Bright c1992:386)

Diagnosis: Near *kleinei* Eggers, distinguished by the smaller size; by the complete absence of interstitial ground setae; and by the uniseriate elytral vestiture. My female of *similis* (ms Eggers ?=*kleinei*) is much larger (1.7 mm) and has the discal interstitial ground setae more abundant and confused, the body is also more slender.

Female: Length 1.3 mm, 2.0 times as long as wide; color reddish brown. Frons and pronotum similar to female *kleinei*. Elytra 1.3 times as long as wide, 1.8 times as long as pronotum; basal margins a continuous transverse costa; striae not impressed, punctures moderately coarse, rather deep; interstriae twice as wide as striae, punctures small, uniseriate to base. Declivity occupying posterior third of elytra length; broadly convex, steep; sculpture about as on disc except striae and interstriae of equal width. Vestiture of uniseriate, fine, short strial hair from base to apex, interstitial ground cover almost entirely absent; erect interstitial setae in uniseriate rows from base to apex, each erect seta stout, about four to five times as long as wide, equal in length to about half distance between rows.

Distribution: Brazil: Faz. Taparinha prox. Santarem, Para, 29-XII-1967-9-I-1968.

Notes: The above treatment was based on the female holotype of *Pycnarthrum uniseriatum* Schedl.

Pycnarthrum bahiae Wood, n. sp.

Pycnarthrum bahiae Wood: Holotype ♂; Cepec, Bahia, Brazil; USNM, Washington, designated below

Diagnosis: Distinguished by the male frontal concave area that ends distinctly below the upper level of the eyes; by the slender body form; and by the slender ground setae on the interstriae of disc and declivity.

Male: Length 1.4–1.7 mm, 2.3 times as long as wide; color yellowish brown to light brown. Frons strongly, broadly concave from epistoma four-fifths of distance to upper level of eyes; surface reticulate, punctures very small, obscure; vestiture of stout hair, mostly on lateral margins, sparse in central area. Pronotum 0.95 times as long as wide; surface reticulate on anterior half, smooth, shining behind, punctures moderately small, rather deep, close, separated by half to full diameter of a puncture; vestiture short, of 2 kinds in about equal numbers, part hairlike, part stouter but very slender. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; costa on basal margins undulating; striae 1 feebly, others not impressed, punctures rather coarse, deep; interstriae about twice as wide as striae, surface smooth, shining, punctures minute, slightly confused. Declivity broadly convex, moderately arched, steep; striae more distinctly

impressed than on disc. Vestiture of ground cover of moderately abundant, fine, interstitial hair on basal half of disc, becoming slightly stouter near and on declivity and very obscurely plumose; and rows of erect setae, each almost twice as long as ground setae, each slender, about eight times as long as wide, equal in length to almost two-thirds distance between rows, spaced within a row by slightly more than length of a bristle.

Female: Similar to male except frons rather strongly convex, its vestiture reduced.

Distribution: Brazil (Bahia).

Type material: The male holotype, female allotype, and 32 paratypes were taken at Cepec, Bahia, Brazil, 11-III-1961, blacklight, Kaston. The holotype, allotype, and paratypes are in the USNM, Washington.

Pycnarthrum subcarinatum Wood

Plate XLVI

Pycnarthrum subcarinatum Wood, 1971:13. Holotype ♂; 8 km SW Bumbum, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:386)

Diagnosis: Distinguished from *carinatum* Wood by the less strongly concave male frons and the weaker epistomal carina; and by the more slender interstitial setae on the disc and declivity.

Male: Length 1.6–2.0 mm, 2.1 times as long as wide; color very dark brown, elytra lighter. Frons with upper half of concave area less strongly impressed than in *carinatum*; transverse epistomal carina shorter, weakly developed, not acutely produced. Setae of pronotum and elytra more slender than in *carinatum*, erect interstitial setae slightly longer, each at least six times as long as wide.

Female: Similar to male except frons convex; epistomal carina smaller; obscurely indicated.

Distribution: Venezuela: 8 km SW Bumbum, Barinas, 11-II-1970, 150 m, No. 327, Charo Blanco (*Brosimum*), SLW.

Biology: Specimens were taken from phloem of broken limbs.

Notes: The above treatment was based on the type-series of 12 specimens.

Pycnarthrum carinatum Wood

Pycnarthrum carinatum Wood, 1971:13. Holotype ♂; 800 m, near Leopampa, Dep. Huanuco, Peru; USNM, Washington (References in Wood & Bright c1992:384)

Diagnosis: Distinguished from *subcarinatum* Wood by the more strongly impressed male frons and more acutely elevated epistomal carina; and by the stouter erect interstitial setae on disc and declivity.

Male: Length 1.8–2.0 mm, 2.1 times as long as wide; color very dark brown. Frons broadly, deeply concave from epistoma to slightly below upper level of eyes; epistoma armed on median one-fifth by an acutely elevated transverse carina; eyes separated above by 1.2

times width of an eye. Pronotum 0.91 times as long as wide; surface smooth, shining, except reticulate on anterior one-fourth; punctures small, deep, close, spaced by half to full diameter of a puncture; vestiture rather short, of two kinds in about equal numbers, part slender, hairlike, part stout to very stout. Elytra 1.25 times as long as wide, about 1.9 times as long as pronotum; basal margins very weakly subcrenulate; striae feebly impressed, punctures rather small, deep, close; interstriae about three times as wide as striae, smooth, shining, punctures very small, almost uniseriate for erect setae, very minute, confused for ground setae. Declivity broadly convex, steep; about as on disc. Vestiture of very small, hairlike setae at base, becoming weakly plumose by base of declivity, more strongly plumose on declivity; and uniseriate rows of erect setae, each twice as long as ground setae, four to six times as long as wide, equal in length to half (disc) to two-thirds (declivity) distance between rows.

Distribution: Bolivia to Peru.

Bolivia: San Esteban, 49 km N Santa Cruz, Et., 7-XII-1959, 1120 ft., R. Cumming.

Peru: Near Leonpampa, Dep. Huanaco, 11-30-XII-1937, 800 m, jungle, No. 3811, F. Woytkowski.

Notes: The above treatment was based on the male holotype from Peru and on 1 male from Bolivia.

GENUS *GYMNOCHILUS* EICHHOFF

Gymnochilus Eichhoff, 1868:399. Type-species: *Gymnochilus zonatus* Eichhoff, monobasic (Synonymy and references in Wood & Bright c1992:386–387)

Problechilus Eichhoff, 1878:46, 167. Type-species: *Gymnochilus zonatus* Eichhoff, automatic

Meringopalpus Hagedorn, 1905:547. Type-species: *Meringopalpus fallax* Hagedorn = *Gymnochilus zonatus* Eichhoff, monobasic

Diagnosis: Distinguished from other genera of Ctenophorini by the 7-segmented antennal funicle; by the pronotum summit being on the posterior third of the pronotum, with coarse asperities on the anterior slope; by the very stout body; by the unique protibia; and by the elytra vestiture.

Description: Length 1.5–2.3 mm, 1.8–2.2 times as long as wide; color light brown or bicolored. Frons flattened to shallowly concave in male, convex in female; eye elongate, entire, finely faceted. Antennal scape elongate, funicle 7-segmented, club rather large, broad, sutures procurved to absent. Pronotum with summit on basal one-third, coarsely asperate on anterior slope; lateral margins costate, basal margin marked by a fine raised line. Scutellum present. Elytral bases with a fine costa or obscure, fine row of subcrenulation; weakly striate, ground vestiture of fine, abundant, short hair. Declivity steep, convex, unarmed. Protibiae with major spine at lateral apical angle small for this tribe and with a significant denticle between this spine and base of terminal mucro (not seen elsewhere in this tribe).

Biology: The species are monogynous, phloeophagous, and parental galleries are transverse and biramous.

Distribution: All species are restricted to tropical America. Although Wood & Bright (c1992:386–387) list 12 species in this genus as directed by literature citations, only *alni* (Mexico), *consocius* (Guatemala to Venezuela), *minor* (Mexico to Costa Rica), *reitteri* (Mexico to Costa Rica), and *zonatus* (Colombia to Venezuela) have been confirmed by me as members of this genus. The seven

remaining species: *alternatus* (Bolivia), *brevis* (Bolivia), *glaber* (Peru), *insularis* (Guadeloupe), *laevicollis* (Bolivia), *pilifer* (Bolivia), and *pilosulus* (Bolivia) all have the antennal funicle 6 segmented, the antennal club and pronotum of the *Scolytodes* type, and lack other essential characters. All 7 of these species are regarded by me as members of *Scolytodes* and are treated in that genus.

Key to the Species of *Gymnochilus*
(Adapted from Wood 1982:462–463)

- 1. Body stout, about 1.8 times as long as wide; antennal club with conspicuous, strongly bisinuate, procurved sutures marked by rows of setae; male frons flattened to below upper level of eyes; female frons more strongly convex; striae punctures usually rather coarse, clearly impressed (variable) elytral bristles very coarse, blunt; Mexico (Durango) to Panama; *Ficus*; 1.5–2.3 mm *reitteri* Eichhoff
- Body more slender, 2.0 times as long as wide; antennal club with sutures obscure or absent, not marked by rows of setae; male frons distinctly impressed to well above upper level of eyes, female frons weakly convex; erect interstitial bristles slender, usually pointed 2
- 2(1). Body more slender, 2.2 times as long as wide; male frons moderately concave to upper level of eyes, striae punctures minute, interstriae five or more times as wide as interstriae; Mexico (Mexico to Puebla); *Alnus*; 2.0–2.2 mm *alni* Wood
- Body stouter, 2.0 times as long as wide; male frons subconcave to well above upper level of eyes; striae punctures larger, interstriae about two to three times as wide as striae 3
- 3(2). Pronotum summit at or very slightly behind middle; asperate area of pronotum rather strongly reticulate on surface between asperities, punctures sparse or usually not evident; asperate area of pronotum occupying anterior two-thirds (67 percent), distance from base to asperities greater in lateral areas than behind summit 4
- Pronotum summit well behind middle of pronotum length; surface between pronotal asperities either reticulate or smooth, shining, with dense, very fine, deep punctures; asperate area of pronotum occupying anterior three-fourths (75 percent), distance from base to asperities equal in lateral and median areas; Guatemala to Venezuela 5
- 4(3). Pronotum anterior slope more distinctly arched, asperities smaller, more numerous; elytral declivity occupying slightly less than posterior half of elytral length, more narrowly convex, steeper; striae feebly or not impressed, punctures very shallow; interstriae about three to four times as wide as striae; erect interstitial setae slender, almost hairlike, spaced within a row by length of a seta or less; Peru; 2.6 mm *vestitus* (Eggers)
- Pronotum anterior slope less strongly arched, asperities coarser, less numerous; elytral declivity occupying distinctly more than posterior half of elytra length, more broadly convex, not as steep; striae distinctly impressed, punctures moderately large, rather deep; interstriae two to three times as wide as striae; erect setae much stouter, most spaced within a row by two to four times length of a seta; Mexico to Costa Rica; *Ficus*; 1.5–1.9 mm *minor* (Blandford)
- 5(3). Smaller; pronotum surface smooth and finely punctured between asperities and on basal areas, punctures on basal one-fourth distinctly smaller; male frons shallowly concave, more strongly impressed, 1.6–1.8 times as long as wide; Guatemala to Brazil (Santa Catarina); *Ficus*; 2.0–2.8 mm *consocius* (Blandford)
- Larger; pronotum surface reticulate, both in asperate and non-asperate areas, punctures on basal one-fourth distinctly larger; male frons 1.5 times as long as wide, much less strongly impressed; Colombia to Venezuela; presumably in *Ficus*; 3.2–3.3 mm *zonatus* Eichhoff

Gymnochilus vestitus (Eggers) n. comb.

Gymnochilus vestitus (Eggers), 1932:233 (Problechilus). Holotype ♂; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:400)

Diagnosis: This species is distinguished from *consocius* Blandford by the more strongly, more narrowly convex slopes of pronotum and elytral declivities; by the very slender, almost hairlike interstitial setae; and by the larger size.

Male: Length 2.6 mm, 2.0 times as long as wide; color dark reddish brown. Frons on lower two-thirds about as in *consocius*, upper third concealed by pronotum on type. Pronotum 0.82 times as long as wide; outline semicircular as seen from dorsal aspect; summit slightly behind middle, indefinite; asperities small and numerous (for this genus); basal area and between punctures strongly reticulate, punctures at base sparse, small, obscure to absent; vestiture partly abraded, ground cover of fine, short, moderately abundant hair, a few longer setae in anterior areas. Elytra 1.35 times as long as wide, 1.8 times as long as pronotum; striae not impressed, punctures small, shallow, smaller near base; interstriae three to four times as wide as striae, surface smooth, shining, with dense, confused, minute punctures, each interstriae near and on declivity with a row of minute granules. Declivity more narrowly convex and steeper than in other members of this genus; sculpture much as on disc. Vestiture of abundant, short, fine interstitial hair and rows of erect, slightly stouter interstitial hair; length of most erect setae half to two-thirds as long as distance between rows, spaced within a row by length of a seta or less.

Distribution: Bolivia: Cochabamba [Woytkowski], Eggers Collection 1948, type.

Notes: The above treatment was based on the male holotype from Bolivia.

Gymnochilus consocius (Blandford)

Plate XLVII

Gymnochilus consocius (Blandford), 1897:171 (Problechilus). Holotype ♂; Cerro Zunil, Guatemala; BMNH, London (Synonymy and references in Wood & Bright c1992:386)

Problechilus trimaculatus Schedl, 1935:91. Holotype ♀; Venezuela [probably Colonia Tovar]; NHMW, Wien

Problechilus novateutonicus Schedl, 1936:105. Holotype, sex?; Nova Teutonia [Santa Catarina], Brazil; NHMW, Wien

Diagnosis: Distinguished from *zonatus* Eichhoff by the absence of reticulation on the pronotum; by the smaller punctures on the basal one-fourth of the pronotum; by the more strongly impressed male frons; and by the smaller size.

Male: Length 2.0–2.8 mm, 1.9–2.0 times as long as wide; usually bicolored, pronotum black except basal fourth pale on elytra base, suture, lower sides, and lower declivity dark, remaining areas pale. Frons broadly, shallowly concave from epistoma to well above upper level of eyes; surface strongly reticulate, punctures small, sparse, obscure; vestiture of fine, short, inconspicuous

hair uniformly distributed; frontal rectangle 1.6–1.8 times as long as wide. Pronotum 0.76 times as long as wide; summit on basal third, coarsely asperate on anterior three-fourths, anterior margin armed by about 14 serrations; basic surface smooth, shining (no reticulation), with numerous very small punctures between crenulations; basal one-fourth densely, minutely punctured; vestiture of fine, short, rather abundant hair; basal margin marked by a fine, raised line. Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; basal margins with obscure costa; striae very weakly impressed; interstriae about three times as wide as striae, surface smooth, shining, feebly convex, punctures minute, rather dense, confused. Declivity broadly convex, steep; striae more deeply impressed than on disc, interstriae narrower. Vestiture of uniformly rather dense, minute, fine hair in ground cover on disc and declivity; erect setae in uniseriate interstitial rows, each seta very slender (not entirely hairlike), those on odd-numbered interstriae longer, each almost as long as distance between rows, spaced within a row by more than length of a seta, those on even-numbered rows mostly half this long; ground setae about one-fifth as long as erect setae.

Female: Similar to male except frons convex.

Distribution: Guatemala to Venezuela and Brazil.

Brazil: Nova Teutonia, Santa Catarina, XII-1934, F. Plaumann.

Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 16-IX-1969, 2500, No. 20, *Ficus*, SLW; Merida, Merida, 7-X-1969, 1700 m, No. 42, *Ficus*, SLW.

Habits: Broken or felled limbs and boles were attacked. Parental galleries were biramous, usually transverse (not always) and engraved the wood slightly. Egg niches were large and were placed alternately on the sides of the tunnel. Larval mines tended to be longitudinal and were entirely in the phloem.

Notes: The above treatment was based on 88 specimens from Venezuela, 2 males of which I compared directly to the male holotype of *Problechilus consocius* Blandford. The types of *Problechilus trimaculatus* Schedl and *P. novateutonicus* Schedl were also examined by me and compared to my specimens.

Gymnochilus zonatus Eichhoff

Gymnochilus zonatus Eichhoff, 1868:399. Holotype, presumably ♂; Colombia; Hamburg Museum, lost (Synonymy and references in Wood & Bright c1992:387)

Meringopalpus fallax Hagedorn, 1905:548. Holotype ♂; Colonia Tovar, Aragua, Venezuela; MNHN, Paris

Problechilus freyi Schedl, 1966:103. Holotype, sex? Venezuela, Rancho Grande, [near] Maracay, Aragua; Frey Museum, now NHMBS, Basel

Diagnosis: Distinguished from *consocius* (Blandford) by the larger size; by the reticulate pronotum; by the larger punctures on the basal fourth of the pronotum; and by the less strongly impressed male frons.

Male: Length 3.2–3.3 mm, about 1.9 times as long as wide; color similar to *consocius*. Frontal rectangle (Wood

1986:4) 1.5 times as long as wide; frons less strongly impressed than *consocius*. Pronotum reticulate between asperities on anterior slope and in posterior areas; punctures on surface of basal one-fourth distinctly larger than in *consocius*.

Distribution: Colombia to Venezuela.

Colombia: "Colombia" (type of *zonatus*).

Venezuela: Colonia Tovar, Aragua (type of *fallax*); Rancho Grande near Maracay, Aragua.

Notes: The holotype of *zonatus* Eichhoff was lost. The male holotype of *fallax* Hagedorn was examined (Wood 1982:466). This holotype was compared to the holotype of *zonatus*, prior to its loss, by Eggers (1936:226) and was declared by him to be synonymous.

GENUS SCOLYTODES FERRARI

Scolytodes Ferrari, 1867:77. Type-species: *Scolytodes laevigatus* Ferrari, monobasic (Synonymy and references in Wood & Bright c1992:387–388)

Hexacolus Eichhoff, 1868:399. Type-species: *Hexacolus glaber* Eichhoff, monobasic

Ctenophorus Chapuis, 1869:49. Type-species: *Ctenophorus laevigatus* Chapuis (preoccupied) = *Hexacolus levis* Blackman (preoccupied) = *Scolytodes chapuisii* Wood, monobasic

Prionosceles Blandford, 1897:177. Type-species: *Prionosceles atratus* Blandford, subsequent designation by Hopkins 1914:128

Epomadius Blandford, 1897:179. Type-species: *Epomadius culcitatus* Blandford, monobasic

Erineophilus Hopkins, 1902:34. Type-species: *Erineophilus schwarzi* Hopkins, original designation

Hylocurosoma Eggers, 1940:138. Type-species: *Hylocurosoma striatum* Eggers, monobasic

Hexacolinus Schedl, 1963:217. Type-species: *Scolytodes minutissimus* Schedl 1963 = *minutissimus* Schedl 1952, original designation

Diagnosis: Distinguished from *Gymnochilus* by the 6-segmented antennal funicle; by the pronotum that may be armed by asperities or not, the summit near the middle of pronotum length or indefinite; and by the basal margin of the elytra marked by a fine, raised line; and by the hairlike vestiture.

Description: Length 0.9–3.5 mm, 1.9–3.5 times as long as wide; color yellowish or reddish brown to black; vestiture hairlike. Frons sexually dimorphic, male usually convex, simple, usually without setal ornamentation, female concave to convex or variously grooved, carinate, or otherwise contoured, usually feebly to elaborately ornamented by hair. Eye elongate-oval, entire, finely to coarsely faceted. Antennal scape moderately long, ornamented by setae or not; funicle 6-segmented; club rather small, sutures absent to rather weakly marked, straight to moderately procurved when visible. Pronotum rather large, lateral margins acutely costate, basal margin sometimes with a less distinct, raised line; surface usually (not always) reticulate and variously punctured, either with or without asperities. Scutellum small, its surface even (flush) with basal surface of elytra. Elytral bases transversely straight or weakly sinuate, with a fine, raised basal margin; disc usually, weakly striate, punctures uniseriate or confused; declivity gradual to very steep, convex, sculpture conservative; vesti-

ture usually sparse to absent, abundant in some groups. Tibiae variable, essentially as described for tribe.

Distribution: Tropical America from Mexico and southern Florida to northern Argentina. Wood & Bright (c1992:388–400) list 176 species, 103 of these were recorded from South America.

Biology: The habits are unusually diverse. While most species are phloeophagous, some breed in *Cecropia* leaf petioles, a few are xylophagous, myelophagous, etc. Most species are monogynous, a few are polygynous. The brood gallery may be a simple cave in which the eggs are scattered in small clusters loose in the frass, or they may form elongate or radiate galleries in which the eggs may be placed individually in niches. Larvae may feed in congress as they extend the parent mine, or they may bore independent mines. In some species larval feeding may begin in the phloem, with later instars moving to the pith. In some species the life cycle is very short. It was observed by me that *phoebeae* Wood and *plumeriae* Wood passed from egg to egg in successive generations in as little as 10 days.

Notes: The protibia of the allies of *atratus* has lateral tooth 1 (at or near the apex) smaller than 2 and a series of 7–9 socketed denticles extending on the lateral margin from there toward the base. In the remainder of the genus tooth 1 is larger than 2 and the number of basal socketed denticles is reduced from none to as many as 6. In most of these latter species, tooth 1 is bent from a laterad direction to an apical direction. Jordal (MS thesis, University of Bergin, Bergin, Norway, 1998) has shown through a sequence of species, that tooth 1 originally had an enclosed socketed denticle that became imbedded within and that this enclosed denticle was gradually lost. My observations confirm Jordal's observations and suggest that through this loss and continued enlargement of lateral spine 1, a protibia like that of Scolytini (*Scolytus*, etc.) logically might be derived. Thus, it is now abundantly clear that the protibia of *Scolytus* was derived independently from that of Curculionidae, from socketed denticles (derived from setae) that were surrounded and reinforced in some groups by adjacent cuticle as the socketed element declined in size and importance and was eventually lost. This generic name has been treated in the past as masculine. A professor of Latin informed me that it is feminine and, for this reason, appropriate name changes in spelling are made below.

Scolytodes grandis (Schedl), rejected name

Scolytodes grandis (Schedl), 1978:122 (*Hexacolus*). Holotype a teratological composit of 3 species; Peru, Machu-Picchu, 2000 m; MHMW, Wien, preoccupied by Schedl 1962:100 (References in Wood & Bright c1992:392)

Scolytodes eximius Wood, 1981:122. A replacement name for *Hexacolus grandis* Schedl (1978) now in *Scolytodes*, type designation automatic

The "holotype" associated with the name *Hexacolus grandis* Schedl, a junior homonym, was examined and found to consist of parts of at least 3 different species of

South American *Scolytodes*. The head (of very dark brown color) is that of a female *S. laevigata* Ferrari, or a very closely allied species (*majus* Wood); the prothorax is of a reddish brown color and represents a smaller species (although attachment was done very cleverly, the larger head does not match the smaller anterior portion of the prothorax; neither the sex nor the species could be determined for the prothorax); the meso- and metathorax and abdomen are from a male specimen of a larger *Scolytodes* species that presently remains unknown to me.

Teratological specimens such as this, artificially united, whether done intentionally or not, fall outside the scope of Zoological Nomenclature and are rejected under the International Code on Zoological Nomenclature (Article 1, Paragraph B, Item 2).

On this particular specimen, the union of parts is so cleverly done that it appears to be a deliberate attempt to mislead Schedl, to whom it was sent. Although the glue joints are entirely hidden, the joined parts are of different sizes and do not match as they do in natural specimens.

Key to the Species of *Scolytodes*

- 1. Elytral interstriae 10 continued posteriorly well beyond level of metacoxae (usually, not always, subcarinate); posterior face of protibia near apex never armed by a small denticle mesad from lateral spines 1 and 2 2
- Elytral interstriae 10 almost never carinate (a few exceptions), ending near or anterior to level of metacoxa; posterior face of protibia armed by a small denticle (usually positioned mesad from bases of lateral spines 1 and 2) 59
- 2(1). Anterior slope of pronotum punctured to anterior margin (if host *Cecropia* then small asperities sometimes intermixed with punctures); protibia with two major denticles on lateral margin, denticle 1 usually smaller than 2 and directed more nearly laterad, lateral margin basad from 2 armed by two to nine denticles; mostly larger, stouter species, body less than 2 times as long as wide; elytral declivity steeper; base of female frontal vestiture never arising above upper level of eyes 3
- Anterior slope of pronotum either punctured or asperate; protibia with lateral denticle 1 usually larger than 2 and directed distad, lateral margin basad from denticle 2 armed by one to five (usually smaller) denticles; body usually more slender than 2.2 times as long as wide; base of some setae in female frontal vestiture above upper level of eyes in some species, not in others 12
- 3(2). Punctures on disc of interstriae 2 and 3 strongly confused; interstitial setae absent on disc, either absent or greatly shortened on declivity 4
- Interstitial punctures on disc usually uniseriate; erect interstitial setae usually present from base to apex 6
- 4(3). Punctures on discal interstriae confused only on 2 and 3, uniseriate on 4–9; erect interstitial setae absent on basal half or all of disc, on declivity much shorter than normal; male frons with a moderate, transverse impression at level of antennal insertion except at median line, female frons more broadly, more strongly impressed on a larger area; Venezuela (Aragua); *Cecropia* leaf petioles; 3.0–3.7 mm *jucunda* Wood
- Discal interstriae 2–9 with punctures confused; all discal interstriae glabrous; male frons uniformly convex from weak, transverse epistomal impression to vertex, female frons more narrowly, more weakly impressed on a smaller area 5
- 5(4). Punctures on pronotum disc small, of almost uniform size; elytral punctures on disc and declivity much smaller; declivital punctures on striae 1 and lower 2 distinctly impressed, in identifiable rows; elytra entirely glabrous; Costa Rica (Limon) to Colombia; *Cecropia* leaf petioles; 2.5–3.1 mm *glabrescens* Wood
- Punctures on pronotum disc moderately large, somewhat irregular in size; elytral punctures distinctly larger, striae 1 and 2 not identifiable on declivity; erect interstitial setae identifiable in rows on lower half of declivity; Bolivia (Cochabamba); probably in *Cecropia* leaf petioles; 4.3 mm *permagna* (Eggers)

- 6(3). Larger species; anterior one-fourth of pronotum armed by small asperities (except female *atratus*); male frons with a rather strong, transverse impression at or near epistoma 7
- Smaller species; anterior pronotum unmarked by asperities (obscure in some male *maurus*); male frons with impression on lower one-third weak, not conspicuous 9
- 7(6). Male frons modestly impressed to lateral margin (without a strong, transverse elevation below level of antennal insertion), female frons much more strongly impressed, a weak median elevation near epistoma; female pronotum without fine asperities; reticulation on pronotum weaker; Mexico (Veracruz) to Panama; *Cecropia* leaf petioles; 2.5–3.3 mm *atrata* (Blandford)
- Male frons abruptly impressed at level of antennal insertion, a subacute, transverse carina below this impression, female frons much less strongly impressed, without a median elevation near epistoma; small pronotal asperities present in both sexes; reticulation on pronotum stronger 8
- 8(7). Male transverse elevation above epistoma less strongly elevated, somewhat rounded, frons less closely punctured; granules on interstrial rows smaller, mostly confined to declivity; Colombia (Antioquia); *Cecropia* leaf petioles; 2.7–3.0 mm *fasta* Wood
- Male transverse elevation above epistoma more strongly elevated, subacute, frons much more closely punctured; granules on interstrial rows larger, more extensive; Venezuela (Caracas); *Cecropia* leaf petioles; 2.3–2.8 mm *suturalis* Wood
- 9(6). Pronotum almost smooth (reticulation obscure); female frons narrowly flattened on a small area; declivital interstriae each with a uniseriate row of granules; Guadeloupe and Venezuela to Peru and Bolivia; *Cecropia* leaf petioles; 1.6–2.0 mm *imitans* (Eggers)
- Pronotum moderately to strongly reticulate; female frons feebly to rather broadly, shallowly concave; declivital interstriae unarmed by granules or with very feeble granules 10
- 10(9). Anterior fourth of pronotum finely asperate, without any punctures between asperities; discal striae 1 and 2 impressed, punctures shallow, declivital striae 1–3 impressed, punctures much smaller, not as deep; body stouter; Brazil (Blumanau); probably in *Cecropia* petioles; 2.0 mm *brasiliensis* (Eggers)
- Anterior fourth of pronotum with crenulations fine to absent, with some punctures indicated to near anterior margin; elytral punctures deeper; body more slender 11
- 11(10). Striae 1 impressed on posterior half of disc and upper declivity, striae punctures larger, not as deep, interstriae on disc twice as wide as striae; male frons with an abrupt, transverse impression on median third just below upper level of eyes, this impression continued orad weaker and more widely expanded, irregular elevations in lateral areas slightly above level of antennal insertions; Brazil; *Cecropia* leaf petioles; 2.4 mm *brasiliana* Wood
- Striae 1 impressed from base of disc to declivity, striae punctures smaller, deeper, closer, interstriae on disc three times as wide as striae; male frons more evenly convex, without any abrupt elevations or impressions on lower two-thirds; Dominica, Mexico (Veracruz) and Panama to Bolivia, Colombia, and Venezuela (Caracas); *Cecropia* leaf petioles; 1.6–2.1 mm *maura* (Blandford)
- 12(2). Pronotum either punctured or asperate; striae setae obsolete; female frons bearing 1 or more conspicuous, longitudinal carinae (sometimes concealed by long hair) 13
- Pronotum either punctured or asperate; female frons never armed by longitudinal carinae (see also *gracilis*) 22
- 13(12). Female frons on median third from epistoma to slightly above antennal insertion with surface smooth, brightly shining, impunctate, broadly sulcate, its lateral margins distinctly elevated, crests of elevations somewhat narrowly rounded, shining; upper half of female frons flattened to upper level of eyes, shining, rather finely, closely, uniformly punctured and bearing fine, long

SCOLYTIDAE OF SOUTH AMERICA

- hair; hair also continued on lower half on lateral thirds to epistoma; anterior fourth of pronotum with punctures continued to anterior margin, a few weak, transverse wrinkles present; elytral surface partly to entirely reticulate; Brazil (Corcovado); 1.7–1.8 mm *gracilis* Schedl
- Pronotum and elytra reticulate; pair of longitudinal carinae on lower female frons acutely elevated 14
- 14(13). Female frons armed by a pair of longitudinal carinae, vestiture continued orad in lateral areas at least half distance from upper level of eyes to epistoma; pronotum smooth, punctured (except very finely asperate in *costabilis*, *obesa*, *minor*) 15
- Female frons with dense brush of hair confined to area above eyes, median area below with a longitudinal elevation, sometimes reduced to a median tubercle 20
- 15(14). Female frontal carinae extending from level of antennal insertions about half distance to upper level of eyes; anterior slope of pronotum armed by numerous, very small asperities; elytral interstriae with uniseriate, bristle-like setae from base to apex, each seta as long as distance between rows, spaced within a row by length of a seta (disc) to half length of a seta (declivity); Bolivia (Cochabamba); 1.7 mm *minor* (Eggers)
- Female frontal carinae extending from epistoma dorsad (either long or short) 16
- 16(15). Carinae on female frons long, extending from epistoma at least half distance to upper level of eyes; pronotum unarmed by asperities 17
- Carinae on female frons short, extending from epistoma to level of antennal insertion; anterior slope of pronotum finely, closely asperate 19
- 17(16). Carinae on female frons very close (subcontiguous), parallel; Costa Rica; *Cecropia* leaf petioles; 1.6–1.9 mm *blandfordi* (Schedl)
- Carinae on female frons rather widely spaced, parallel 18
- 18(17). Apex of elytra rather narrowly rounded, minute setae on lower half of declivity confused on striae and interstriae; Costa Rica; *Cecropia* leaf petioles; 1.5–1.8 mm *acuminata* Wood
- Apex of elytra more broadly rounded behind, minute setae on lower declivity restricted to interstitial rows, absent on striae; Costa Rica; *Cecropia* leaf petioles; 1.5–1.8 mm *cecropiavora* Wood
- 19(16). Body more slender, 2.3 times as long as wide; female frons sometimes flattened, with a large impunctate, median callus; Mexico (Veracruz); 2.2 mm *costabilis* Wood
- Body rather stout, 2.0 times as long as wide; female frons feebly concave, without a central callus; Panama (Canal Zone); at light; 1.9 mm *obesa* Wood
- 20(14). Female median frontal elevation low, double crested, not higher at lower end, dense tuft of hair above upper level of eyes very slightly narrower than distance between eyes; Costa Rica; *Cedrela mexicana*, *Vismia guianensis*; 1.3–1.5 mm *cedrelae* Wood
- Female median frontal elevation tuberculately elevated at its lower end, continuing upper subcarinate portion appearing granular and single crested, tuft of hair above eyes very slightly wider than distance between eyes (at bases of setae where these arise) 21
- 21(20). Female tubercle at lower end of median elevation without an acutely elevated crest continuing orad; Venezuela to Suriname and Brazil; *Swietenia*, *Carapa guianensis*; 1.4–1.7 mm *guyanaensis* (Schedl)

- Female median frontal elevation with an acutely elevated, very low carina continuing from base of tubercle to epistomal margin; Costa Rica; *Swietenia*, *Cedrela*; 1.7–1.9 mm *swieteniae* (Blackman)
- 22(12). Eyes separated above by less than one-third width of an eye, very coarsely faceted; female frons with an obtuse, subcarinate, transverse elevation above middle, surface reticulate, subglabrous; strial and interstitial setae restricted to sides and declivity; Colombia; *Clusia*; 1.9–2.2 mm *ommatea* Wood
- Eyes much more widely separated above; strial and interstitial pubescence usually much more numerous to base; female without a transverse elevation on frons 23
- 23(22). Female frons almost glabrous, setae very short, sparse, restricted to lower half on median one-third 24
- Female frons with pubescence more abundant, more widely distributed, a central glabrous area present in some species 30
- 24(22). Female frons transversely impressed on lower two-thirds (not at all concave), surface minutely, not clearly micropunctate from epistoma to upper level of eyes; impressed area on frons with very fine, uniformly distributed, sparse, inconspicuous hair of moderate length; body slender, 2.7 times as long as wide, pronotum 1.2 times as long as wide; anterior slope of pronotum asperate; interstitial setae on disc absent, on declivity small, uniseriate; Venezuela (Moritz, presumably at Colonia Tovar); 1.7 mm *parallela* (Schedl)
- Female frons more generally flattened, not conspicuously, transversely flattened or longitudinally concave 25
- 25(24). Female frons almost glabrous, median one-third on lower four-fifths distinctly impressed; body stouter, 1.8 times as long as wide; striae rather coarsely, deeply punctured, interstriae about twice as wide as striae, punctures uniseriate, rather coarse, almost as large as those of striae; Costa Rica; *Cecropia* twigs; 1.8–2.2 mm *cecropicolens* Wood
- Female frons subglabrous, shallowly, rather broadly impressed on lower half; body more slender, at least 2.3 times as long as wide; strial and interstitial punctures small, shallow, elytra glabrous 26
- 26(25). Female frons with epistoma feebly elevated, without a median callus; elytral declivity with strial punctures small to minute, interstitial punctures of equal or smaller size compared to those of striae and confused 27
- Female frons with a weakly elevated median callus above epistoma; declivital punctures on striae slightly larger, interstitial punctures larger, almost uniseriate 29
- 27(26). Pronotum mostly smooth, shining, weak reticulation on basal third, punctures very minute (diameter equal to thickness of a seta); discal interstriae at least six times as wide as striae, interstitial punctures about one-third as large as those of striae; Bolivia (Cochabamba); 2.1 mm *maja* Wood
- Pronotum moderately reticulate over entire surface, punctures small, diameter equal to at least three times thickness of a seta; discal interstriae about three to four times as wide as striae, interstitial punctures about half as large as those of striae; Panama; 2.5 mm 28
- 28(27). Color almost black; female frons feebly convex above level of antennal insertion, punctures below level of antennal insertion much smaller, less numerous; surface of elytral disc mostly smooth, shining, many irregular lines; Colombia (probably Venezuela) to Panama; 2.5 mm *laevigata* Ferrari

- Color dark reddish brown; female frons feebly concave above level of antennal insertion, punctures below level of antennal insertion larger, less numerous; surface of elytral disc partly smooth, shining, with many impressed irregular lines; punctures on lower half of declivity smaller, more completely confused; Costa Rica; *Agreratina* c.f. *ixiocladon*; 2.2–2.3 mm *ageratinae* Wood
- 29(26). Female frons planoconvex on lower seven-eighths to just below upper level of eyes, transverse epistomal callus with a narrow median extension to slightly above level of antennal insertion; Argentina; 2.1 mm *tucumani* Wood
- Frons shallowly, concavely impressed on middle one-third of median half, transverse epistomal callus obscure to obsolete, a shining impunctate callus on median one-fourth from epistoma to slightly above level of antennal insertion; Brazil; 2.5 mm *trispinosa* Eggers
- 30(23). Female frons more strongly convex, vestiture confined to lower two-thirds of area below upper level of eyes, smooth, impunctate, median shining area smaller, confined to less than lower one-third; pronotum disc moderately reticulate 31
- Female frons more extensively flattened, vestiture extending to or above upper level of eyes, smooth, impunctate, median shining area, when present, extending at least to middle of area below upper level of eyes; pronotum disc reticulate or sometimes smooth, shining 35
- 31(30). Interstriae 10 flat, not carinate (mesal margin abrupt on basal half), clearly extending well beyond level of base of declivity; distal half of scape ornamented by a large tuft of hair; female frons distinctly convex, uniformly pubescent except median one-fourth of lower area 32
- Interstriae 10 carinate from base at least to base of declivity; scape never with a conspicuous tuft of long hair; female frons more distinctly flattened (see also *similis* Eggers) 33
- 32(31). Declivital interstriae without sparse rows of erect setae; female frons on median one-fifth of lower half with a distinct elevation, surface of elevated area ornamented by large shallow punctures, without a median, smooth impunctate area, lateral and upper areas finely, closely punctured, vestiture short, more abundant, uniformly distributed except on ornamented area; Peru (Amazonas); at light; 2.6–3.1 mm *peruana* Wood
- Declivital interstriae with sparse rows of moderately long, erect interstitial setae; female frons rather weakly concave, median half of more than lower half smooth, shining, impunctate, lateral and upper areas sparsely punctured, vestiture sparse, rather long, dorsal fringe inconspicuous but present; Venezuela; *Clusia* sp.; 2.6–3.1 mm *canalicula* Wood
- 33(31). Pronotum very finely asperate on anterior fourth without any acute crests; female frons with small pubescent area flattened, without any granules, vestiture of fine hair of moderate length on central half of lower two-thirds; striae and interstitial punctures larger; elytra entirely glabrous; Guadeloupe and Panama to Venezuela; *Cecropia* twigs; 1.6–1.8 mm *ovalis* (Eggers)
- Pronotum without any asperities or acute, transverse wrinkles, punctured to anterior margin; striae punctures small, interstitial punctures minute 34
- 34(33). Body larger, more slender, 2.3 times as long as wide; pronotum disc weakly reticulate, subshining; elytral declivity steeper, occupying posterior third of elytra length, very minute interstitial hair on disc and declivity, their length about equal to diameter of a striae puncture; female frons evenly convex on lower two-thirds, surface shining, with rather abundant small, rounded tubercles, vestiture of fine, long hair of moderate length uniformly distributed; Mexico (Jalisco); *Plumeria rubra*; 1.5–1.6 mm *plumericolens* Wood
- Body smaller, stouter, 2.1 times as long as wide; pronotum disc almost smooth, shining, punctures minute; elytral declivity more gradual, occupying posterior 40 percent, elytral disc and declivity entirely glabrous; female frons basically convex, somewhat flattened on lower two-thirds, median one-fifth on middle half forming a weakly elevated, convex, impunctate, subshining callus, its lateral

	margin obscurely punctured half distance to antennal insertions, punctured area with fine, short hair (setae not extending dorsad above upper end of callus); Costa Rica; 1.2 mm	
	<i>minutissima</i> Schedl
35(30).	Female frons with pubescence extending only to near upper level of eyes; pronotum smooth, shining	36
—	Female frons with pubescence extending to or well above upper level of eyes (usually to vertex); pronotum reticulate, sometimes dull	41
36(35).	Female scape with a tuft of long hair; epistoma in one or both sexes armed by a small median tubercle; elytral declivity much steeper; setae on female frons more abundant in lateral and dorsal areas	37
—	Female scape without a tuft of long hair; epistoma without a median tubercle in either sex	39
37(36).	Female epistoma armed by a median, flattened, pyriform process on lower fourth, antennal insertions displaced dorsad; frontal impression broad, extending distinctly above upper level of eyes, vestiture of dense, short, fine setae, especially dense near glabrous, elevated process; tuft of hair on female scape only; Guatemala and Costa Rica to Peru; 2.2–2.5 mm	
	<i>unipunctata</i> (Blandford)
—	Epistoma armed by a small tubercle in both sexes	38
38(37).	Upper setae on female frontal tuft arising at or very slightly below upper level of eyes, tips of upper setae capable of extending about half distance toward level of antennal insertions; strial punctures smaller, not as deep, most spaced by diameter of a puncture or more; most interstitial punctures minute, less than one-third as large as those of striae; declivity more evenly convex, suture as high or higher than interstriae 2; Brazil (Corcovado); 2.0 mm	
	<i>perplexa</i> Schedl
—	Setae on female frons extending distinctly above upper level of eyes, tips of these upper setae capable of extending to level of antennal insertions; strial punctures on disc larger, deeper, closer; interstitial punctures larger, half to two-thirds as large as those of striae; declivity with striae 1 distinctly impressed, suture and interstriae 1 not as high as 2 or 3; Colombia; <i>Clusia</i> ; 2.4–2.9 mm	
	<i>praeceps</i> Wood
39(36).	Female frons flattened and finely punctured on a broad, subcircular area from epistoma to slightly above upper level of eyes, a distinct median, impunctate callus on lower half usually hidden by setae; pronotum feebly asperate on anterior slope, disc weakly reticulate; punctures on elytral disc small, somewhat confused; Costa Rica; <i>Ficus</i> ; 1.4–1.9 mm	
	<i>pseudopicea</i> Wood
—	Female frontal vestiture shorter; shining area less conspicuous; strial punctures on disc in definite rows, not confused with those of interstriae	40
40(39).	Female frons rather coarsely, closely punctured except smooth and shining on median one-sixth of lower two-thirds, vestiture at margins very long; strial punctures small, rather deep, interstitial punctures on 2 and 3 small, almost uniseriate; Guatemala to Costa Rica; <i>Plumeria rubra</i> , <i>Ficus</i> ; 1.4–1.8 mm	
	<i>venusta</i> Wood
—	Female frons rather finely, closely punctured except smooth and shining on triangular area on median one-third of lower two-thirds, vestiture of fine, long hair, longer on margins; strial punctures small, rather shallow; interstitial punctures on 2 and 3 small, confused; Guatemala to Costa Rica; <i>Plumeria rubra</i> ; 1.9–2.7 mm	
	<i>plumeriae</i> Wood
41(35).	Body stouter, less than 2.2 times as long as wide, declivity steeper; strial punctures on disc moderately large, interstitial punctures often equally large (punctures confused in <i>phoebeae</i>); female frons flattened on a subcircular area; pubescence extending to or only slightly above upper level of eyes (to vertex in <i>phoebeae</i>), circular central area either shining or with micropunctures; mostly smaller species	42

- Body more slender, at least 2.4 times as long as wide, declivity more gradual; striae punctures on disc small, rather shallow, interstriae punctures minute; female frons with pubescence extending to vertex, ornamented on dorsal and lateral margins by a fringe of long, yellow hair, epistomal margin largely without pubescence, large central area smooth, shining 50
- 42(41). Pronotum punctured on anterior slope to anterior margin, with no indication of asperities (obscure wrinkles in *puer*); female frontal vestiture sometimes extending above upper level of eyes 43
- Anterior slope of pronotum clearly asperate, either with or without punctures intermixed with asperities; female frontal vestiture attaining only upper level of eyes 47
- 43(42). Epistoma with a distinct median tubercle in both sexes; female frons with flattened area poorly defined, on lower half, vestiture of sparse, short, inconspicuous setae to upper level of eyes; Venezuela; *Chusia*; 2.2–2.5 mm *crinalis* Wood
- Epistoma without a median tubercle, flattened area more definite and more extensive 44
- 44(43). Striae punctures discernible, in rows, interstriae punctures smaller; female frontal vestiture attaining only upper level of eyes, pubescent area rather widely spaced from margin of eye; Bolivia (Cochabamba); 1.9 mm *nitida* (Eggers)
- Elytral punctures moderately coarse, moderately to strongly confused; female frons with abundant setae extending to vertex 45
- 45(44). Larger species; striae punctures confused with those of interstriae from base to apex, striae not discernible at base; female frontal pubescence extending to vertex, well above upper level of eyes; Costa Rica; *Phoebaea mexicana*; 2.3–2.5 mm (Plate LVI, figs.) *phoebaea* Wood
- Smaller species; striae punctures on 1–4 in distinct rows on basal half of disc, interstriae punctures confused on 2 and 4; female frontal pubescence (apparently) not extending above upper level of eyes 46
- 46(45). Punctures on discal interstriae 3 and 5 uniseriate; female frons finely, closely, uniformly punctured, except with a smooth, shining area on less than median half of lower half; pronotal punctures continue to anterior margin, asperities transversely elongate; Argentina; 2.1 mm *frontoglabrata* (Schedl)
- Punctures on discal interstriae 2–5 confused; female frons finely, closely, uniformly punctured over entire area; pronotal punctures continue to anterior margin, asperities transversely elongate; Paraguay; 1.8 mm *puer* (Schedl)
- 47(42). Female frons pubescent on a circular pattern to upper level of eyes, subcircular central area smooth, shining (no setae); anterior half of pronotum rather coarsely asperate, posterior half almost smooth, shining (reticulation obscure), punctures rather coarse, close 48
- Female frons with pubescence extending very slightly above upper level of eyes, central area within circular fringe densely micropunctate or granulate; pronotal asperities distinctly smaller, confined to less than anterior half 49
- 48(47). Impunctate central area on female frons smaller; asperities on anterior half of pronotum smaller; reticulation on pronotum disc much stronger, punctures much smaller; Brazil (Paraná); 1.4 mm *nitella* (Schedl)
- Impunctate central area on female frons much larger; asperities on anterior half of pronotum rather coarse; reticulation on pronotum disc rather obscure, punctures much larger; Bahama Islands and Florida to Mexico (Jalisco, Veracruz); *Ficus*; 1.3–1.6 mm *schwarzi* (Hopkins)

- 49(47). Female frons with setae in circular margin much longer; length of each almost as great as diameter of central area, central area flat to feebly concave, surface densely micropunctate becoming smooth at and near epistoma; disc of pronotum moderately reticulate; striae punctures moderately small, in rows, interstriae punctures uniseriate, somewhat variable in size; Panama; 1.7 mm
..... *panamensis* Wood
- Female frons with setae in circular margin shorter; equal in length to less than one-third diameter of central area, central area feebly concave, surface very minutely, densely granulate, an impunctate, transverse shining area just below middle on more than median half, a short extension of shining callus directed orad at median line; disc of pronotum rather weakly reticulate; interstriae punctures strongly confused on disc and declivity, striae punctures larger and uniseriate near base, smaller and confused with those of interstriae behind; Mexico (Jalisco, Tamaulipas); *Ficus*; 1.9–2.3 mm *amoena* Wood
- 50(41). Female frons broadly flattened, vestiture uniformly distributed (apparently distributed from epistomal lobe to vertex), without a smooth, shining area; oral fossa very broad, epistomal lobe large, punctured and pubescent, occupying median half; declivital striae impressed, interstriae convex, 2 and 4 ending at or slightly below middle of declivity; pronotum and elytra glabrous; Colombia; *Virola* log; 2.3–2.4 mm *declivistriata* Schedl
- Female frons with a smooth, glabrous area; declivital striae 2 and 4 continue to lower half of declivity 51
- 51(50). Pronotum and elytra moderately to strongly reticulate; female frons with smooth, shining area confined to median one-third on lower half, lateral and dorsal areas rather coarsely, deeply punctured, setae moderately abundant, rather long; eyes separated above by 2.0 times width of an eye; striae punctures small, shallow, interstriae punctures minute, uniseriate; Guatemala; *Ficus*; 1.4–1.6 mm *faceta* Wood
- Elytra almost smooth, shining (no reticulation); female frons with smooth, shining area extending at least three-fourths distance from epistoma toward upper level of eyes, lateral punctured areas finer, narrower, setae extending higher on vertex; eyes spaced above by about 2.0–4.0 times width of an eye 52
- 52(51). Interstriae 10 almost flat, present but only weakly convex on its distal half 53
- Interstriae 10 subacutely convex throughout its length 54
- 53(52). Larger species; mesothoracic tibia slender, armed by 9 socketed denticles; Costa Rica; *Miconia*; 3.3–3.5 mm *immana* Wood
- Smaller species; mesothoracic tibia distinctly wider, armed by 7 socketed denticles; Costa Rica to Panama; *Cecropia peltata*, *Phoebe mexicana*; 1.8–2.0 mm *picea* (Blandford)
- 54(52). Pronotum punctured to anterior margin, asperities absent 55
- Pronotum with anterior slope asperate, punctures eliminated before attaining anterior margin ... 58
- 55(54). Discal striae obsolete, not evident, area of interstriae 2 and 4 with numerous, small, confused punctures, area of 3 with punctures almost uniseriate; punctures on pronotum continue to anterior margin, with no wrinkles or asperities; area of female frons above upper level of eyes hidden by pronotum on available specimen, glabrous; shining area on median half extending at least half distance toward upper of eyes; Argentina; 2.2 mm *bruchi* (Hagedorn)
- Discal striae clearly indicated, punctures on interstriae 1–3 almost uniseriate 56
- 56(55). Anterior slope of pronotum reticulate to anterior margin, punctures not associated with transverse wrinkles; striae and interstriae punctures minute, interstriae more than five times as wide as striae (striae punctures as small as punctures on pronotum disc); setae on lateral margins of female frons less numerous; Venezuela; *Cecropia* leaf petioles; 1.8–2.2 mm *chapuisi* Wood

- Anterior slope of pronotum mostly shining to reticulate, punctures associated with transverse wrinkles (a pre-asperate condition); stria punctures larger, interstriae about three times as wide as striae (stria punctures about three times larger than those on pronotum disc; setae on lateral margins of female frons more abundant 57
- 57(56). Pronotum more weakly reticulate, some areas almost smooth, shining; punctures on pronotum disc rather small; peripheral fringe of hair on female frons continued on lateral margins to well below eye, tips of some setae on vertex attaining epistomal margin; body 2.7 times as long as wide; Venezuela (Merida); *Mariana*; 2.7–3.1 mm *serina* Wood
- Pronotum uniformly rather strongly reticulate; punctures on pronotum disc minute; peripheral fringe on female frons sparse to absent, tips of longest setae not attaining epistoma; Costa Rica; *Gunnera insignis*; 3.0–3.6 mm *gunnerae* Wood
- 58a(54). Pronotum 1.2 times as long as wide, a definite summit anterior to middle; body slender, 2.7 times as long as wide; stria punctures less strongly impressed, about equal in size to those of pronotum disc; dorsal margin of pubescent area on female frons rather narrowly arched, setae much less abundant on both dorsal and lateral margins; Costa Rica; *Alnus acuminatus*; 2.4–2.9 mm (Plate XLVIII, figs.) *alni* Wood
- Pronotum as wide or wider than long; body less slender, 2.3–2.5 times as long as wide; stria punctures more strongly impressed, distinctly larger than those on pronotum disc; dorsal margin of pubescent area on female frons ending at upper level of eyes or its upper margin, much more broadly arched 58b
- 58b(58a). Dorsal margin of female frontal pubescence extending to upper level of eyes, row of setae rather sparse, much shorter; body 2.5 times as long as wide; pronotum 1.0 times as long as wide; punctures on basal half of discal interstriae 2 uniseriate; Brazil (Sao Paulo); 1.6–1.7 mm *bicolor* (Eggers)
- Dorsal margin of female pubescence on frons extending well above upper level of eyes, its dorsal margin broadly arched, setae dense, more widely distributed; body 2.3 times as long as wide; pronotum 0.9 times as long as wide; punctures on basal half of disc on interstriae 2 confused; Panama (Canal Zone); 1.8–2.1 mm *perdita* Wood
- 59(1). Pronotum with punctures distributed from base to anterior margin (subconcentric long rugae present in *lepida* but with punctures conspicuously present to anterior margin, also with interstriae 10 present on posterior half) 60
- Anterior one-fourth of pronotum armed by asperities that entirely replace punctures; female frons essentially convex, with sparse vestiture, never extending to upper level of eyes; interstriae 10 almost never extending behind level of metacoxae 81
- 60(59). Strial setae obsolete, interstitial setae uniseriate, if present; interstriae 10 sometimes evident on posterior half (beyond level of metacoxae); female frons variously sculptured, frontal setae more abundant and longer than in male 61
- Strial setae conspicuously present (except absent in *radiata*), interstitial setae more numerous, often confused (sometimes with uniseriate, erect rows and also short, confused ground setae); female frons convex, setae sparse, not longer or more abundant than in male 71
- 61(60). Interstriae 10 extending to level of abdominal sternum 3 or beyond; female frontal vestiture extending up to very slightly above upper level of eyes 62
- Interstriae 10 not extending beyond level of metacoxae; female frontal vestiture extending well above upper level of eyes 63
- 62(61). Anterior third of pronotum asperate, asperities confused, transversely elongate, rugae, short and near summit when present; stria punctures clearly in rows, distinctly larger than confused interstitial

- punctures; female frons on median half of lower half with a large, obscurely quadrate impunctate, shining callus, a finely, densely punctured area on median two-thirds from callus to upper level of eyes, a fringe of long hair extending from above upper level of eyes down lateral areas to epistomal brush; Brazil (Sao Paulo); 2.5–2.7 mm *pseudoacuminata* (Schedl)
- Anterior one-third of pronotum armed by subconcentric rows of subacute crests or ridges, with moderately coarse punctures in intervening areas; elytral punctures rather coarse, moderately confused on posterior half; female frons with moderately long, rather abundant vestiture except for glabrous median callus at and slightly above level of antennal insertions on median one-fifth; Mexico (Jalisco); *Ficus*; 1.8–2.3 mm *lepida* Wood
- 63(61). Lower female frons convex, median one-sixth on lower half distinctly, longitudinally sulcate (surface of sulcus smooth, shining), lateral margins of sulcus distinctly elevated and bearing rows of fine, isolated, shining granules (apparently 4 longitudinal rows on each side), very long setae on vertex extending to level of antennal insertion, somewhat shorter laterally; Mexico (Chapias); *Quercus*; 1.4–1.7 mm *canalis* Wood
- Female frons at least shallowly concave (flat in *fulminea*) 64
- 64(63). Female frons punctured and pubescent to lateral margins, without lateral calluses 65
- Female frons with a pair of distinctly elevated, smooth, shining, longitudinal calluses near or on lateral margins 69
- 65(64). Female frons with median half smooth, shining, impunctate from epistoma almost to upper level of eyes, lateral areas finely, closely punctured to upper level of eyes, setae erect, short, length of longest equal to about one-sixth distance between eyes; interstitial punctures almost obsolete; Venezuela; *Clusia*; 1.6–1.9 mm *fulminea* Wood
- Female frons with shining areas obsolete to much smaller; interstitial punctures present, at least in part 66
- 66(65). Female frontal rectangle wider than long, vestiture more evenly distributed, little if any longer on dorsal margin, ending at upper level of eyes; very minute striae setae usually on declivity, occasionally on disc 67
- Female frontal vestiture extending well above eyes, setae on dorsal margin more abundant, much longer; striae setae obsolete 68
- 67(66). Female frons shining between abundant, uniformly distributed punctures, surface very weakly concave from level of antennal insertions to upper level of eyes, a smooth, shining, impunctate callus from epistoma to level of antennal insertion on median one fifth; Mexico (Veracruz) to Guatemala; *Clusia*; 1.3–1.6 mm *clusiavora* Wood
- Female frons reticulate between punctures, surface moderately, broadly concave on central two-thirds, without a shining callus; Costa Rica; *Clusia*; 1.7–1.9 mm *clusiae* Wood
- 68(66). Strial punctures on disc minute; female frontal impression on median two-thirds strongest on lower half, extending well below upper level of eyes, setae on lateral margins much more abundant; Costa Rica; *Cecropia* leaf petioles; 0.9–1.0 mm *acares* Wood
- Strial punctures on disc rather small; female impression on frons rather weak, strongest on upper two-thirds, surface uniformly, finely granulate-punctate, setae sparse below, moderately abundant above; Costa Rica; tree seedling; 1.2–1.3 mm *volcanus* Wood
- 69(64). Female frons with a pair of longitudinal, impunctate, smooth, shining calluses spaced by one-third width of frons extending from distinctly above upper level of antennal insertions to distinctly above level of eyes; striae punctures small, shallow, interstriae shining, punctures mostly obsolete, declivity without striae setae, interstriae 3, 5, and 7 each with one or two setae; E. Costa Rica; *Cecropia* leaf petioles; 0.9–1.0 mm *parvula* Wood

SCOLYTIDAE OF SOUTH AMERICA

- Female frons with a pair of longitudinal, smooth, shining calluses spaced by half width of frons, beginning at level of antennal insertions and extending to distinctly below upper level of eyes, fringe setae more definite, especially above 70
- 70(69). Strial and interstitial punctures rather coarse, deep, uniseriate, declivity with minute strial hair; impressed area of female frons finely punctured, rows of setae on lateral and upper margins well formed, rather short, not longer or of greater abundance above; Costa Rica; tree branches; 1.4–1.9 mm *irazuensis* Wood
- Strial setae very small, shallow, interstitial punctures minute to obsolete; strial setae on declivity very minute; impressed area of female frons finely punctured, row of setae on lower one-third of lateral areas obsolete, dense and much longer on dorsal margin; Colombia; *Cecropia* leaf petioles; 1.3–1.4 mm *anceps* Wood
- 71(60). Strial setae minute to absent, interstitial setae sparse to obsolete; mature body color black; frons strongly convex in both sexes, setae sparse to obsolete (see also *fulminea*, *clusiavora*, *clusiae*; host mostly *Clusia*) 72
- Pronotum and elytra with abundant pubescence, strial setae conspicuous, often as long as those of interstriae 75
- 72(71). Strial and interstitial setae absent; interstitial punctures on disc smaller, more widely spaced, most spaces equal in length to width of an interstriae; Costa Rica; *Quercus*; 1.7–2.0 mm *radiata* Wood
- Minute strial punctures present, interstitial punctures present to or near base 73
- 73(72). Interstitial punctures on disc very feebly granulate; setae on all interstriae of about equal length; posterior half of pronotum with minute, hairlike setae; Mexico (Michoacan) to Honduras; *Clusia*; 1.8–2.9 mm *clusiacolens* Wood
- Interstitial punctures on disc not at all granulate; interstitial setae on 2, 4, and 6 minute, part of those on 1, 3, and 5 much longer; posterior half of pronotum glabrous 74
- 74(73). Body rather stout, 2.0 times as long as wide; strial punctures moderately large, more than half as wide as an interstriae; interstitial punctures minute; strial and interstitial setae minute, except sparse long setae on odd-numbered interstriae; Panama (Canal Zone); at light; 1.0 mm *crassa* Wood
- Body slender, 2.4 times as long as wide; strial punctures smaller, deeper, less than half as wide as an interstriae; strial and interstitial punctures minute, setae short except a moderate number of long setae on odd-numbered interstriae; Panama (Chiriqui); *Oreopanax xalapense* seedling; 1.3–1.5 mm *venustula* Wood
- 75(71). Setae on elytral declivity recumbent or semirecumbent, confused, none in discernible rows 76
- Declivital setae with at least longest setae erect, interstitial setae in definite rows 77
- 76(75). Body 2.1 times as long as wide; strial and interstitial punctures in uniseriate rows on anterior two-thirds of disc, on declivity interstitial punctures much more numerous, strongly confused; elytral setae much less abundant on basal half, some setae erect; Venezuela; tree bole; 1.7–2.0 mm *semipunctata* Wood
- Body 2.4 times as long as wide; strial and interstitial punctures rather small, strongly confused from base; elytral vestiture more numerous from base, recumbent; Venezuela; *Croton*; 1.5–1.7 mm *habilis* Wood
- 77(75). Strial and interstitial punctures on disc in identifiable rows, strial and interstitial setae in rows 78

CTENOPHORINI

—	Elytral punctures confused, interstitial setae confused except for central row on each conspicuously longer than most ground setae	79
78(77).	Strial setae on declivity about half as long as distance between rows, interstitial setae as long as distance between rows, erect, slightly stouter; declivital punctures in recognizable rows; Venezuela; <i>Nectandra</i> ; 1.4–1.6 mm	<i>decora</i> Wood
—	Strial setae on declivity about as long as distance between rows, interstitial setae one and one-half times as long as distance between rows, very fine, mostly curved; declivital punctures confused; Ecuador to Bolivia; 1.9 mm	<i>punctata</i> (Eggers)
79(77).	All punctures on elytral disc and declivity small, confused (striae 1 sometimes discernible); Costa Rica; liana; 1.7 mm	<i>hirsuta</i> Wood
—	Strial punctures on disc slightly larger, in discernible rows	80
80(79).	Strial punctures on disc slightly larger, deeper than those of interstriae, as large as those of pronotum; Costa Rica; <i>Oreopanax nubigenus</i> ; 1.5 mm	<i>punctifera</i> Wood
—	Strial punctures much smaller, little larger than those of interstriae, pronotal punctures small, shallow; rows of erect interstitial setae on declivity in addition to ground cover; Colombia; <i>Croton guianensis</i> ; 1.4–1.5 mm	<i>vescula</i> Wood
81(59).	Interstriae 10 continued to level of base of declivity; female frons flattened and ornamented by a fringe of long setae; elytral setae (or interstitial punctures) sometimes confused, small to very minute	82
—	Interstriae 10 ending at or before level of hind coxae (except longer in <i>morulus</i>); frons convex and with sparse pubescence	95
82(81).	Female frontal pubescence not attaining upper level of eyes (upper half of pubescent area with a weak pair of smooth, shining calluses in 1 species)	83
—	Female frontal pubescence clearly extending above upper level of eyes	90
83(82).	Female frons punctured to center	84
—	Female frons with a large, impunctate shining area	87
84(83).	Female frons with a low, acute median carina on lower half, vestiture long, rather abundant, longest at margins; strial and interstitial punctures on disc moderately coarse, in rows except confused on 2; elytra glabrous; Brazil; 1.5–1.8 mm	<i>glabrella</i> (Schedl)
—	Female frons without a median carina, vestiture slightly shorter, less abundant; strial punctures on disc smaller; interstitial punctures on disc small to absent, setae present or not	85
85(84).	Strial punctures very large, deep, striae wider than interstriae; punctures on pronotum coarse, deep, very close; Bolivia (Cochabamba); 1.2 mm	<i>pusilla</i> (Eggers)
—	Strial punctures rather small, shallow, striae less than half as wide as an interstriae; punctures on pronotum very small, shallow, rather widely spaced	86
86(85).	Female frontal setae sparse, uniformly distributed below a low, weak, short transverse carina, without setae above carina; elytral declivity with sparse, erect setae on odd numbered interstriae; Argentina; 1.9–2.0 mm	<i>sparsepilosa</i> Wood
—	Female frons with a pair of obscure, longitudinal, shining, impunctate areas on median one-third on upper half of pubescent area; elytra glabrous; Venezuela; <i>Clusia</i> ; 1.3–1.7 mm . . .	<i>naevia</i> Wood

- 87(83). Elytra with strial and interstitial setae present on disc and declivity, declivity also with rows of erect interstitial setae; female frons with impunctate area as wide as distance between eyes, occupying lower two-thirds of distance from epistoma to upper level of eyes, setae at margins sparse, not forming a definite row at margin, weak above; Costa Rica; *Ficus*, *Rheedia edulis*; 1.3–1.7 mm
 *erineophila* Wood
- Strial and interstitial setae absent, sparse (if present) behind; female frontal setae more conspicuous 88
- 88(87). Elytral disc clearly reticulate; declivity with very minute strial and interstitial setae (length of each less than diameter of a puncture), occasional erect setae sometimes present on odd-numbered interstriae on posterior half; smooth, impunctate shining area on female frons occupying median one-third of lower one-half, marginal fringe subcircular; setae rather long; Mexico (Puebla to Michoacan); *Ficus*; 1.5–2.0 mm *reticulata* (Wood)
- Elytral disc smooth (not reticulate), strial setae absent 89
- 89(84). Female frontal smooth, impunctate area beginning at epistoma, longer than wide, occupying slightly more than lower half; elytral punctures distinctly larger, deeper, glabrous; Guatemala; 1.5–1.7 mm *ficivora* Wood
- Female frons with central, smooth, shining, impunctate area circular in outline, beginning at level of antennal insertion and ending distinctly below upper level of eyes, pubescent margin circular, as wide as long; odd-numbered interstriae each with about one to four erect setae on declivity; Venezuela; *Cecropia* leaf petioles; 1.3–1.9 mm *pilifrons* (Schedl)
- 90(82). Female frons with a pair of longitudinal carinae near lateral margins on middle half, central area very weakly concave, pubescent area mostly at margins, about equally distributed above and below; Venezuela; *Ficus*; 1.7–1.9 mm *ficicolens* Wood
- Female frons without a pair of carinae in lateral areas 91
- 91(90). Female frons with a large, median, glabrous area on lower half (without a median crest) 92
- Female frons with a weak median crest, surface at center somewhat granulate, not smooth 94
- 92(91). Female frons rather strongly concave on central two-thirds, impressed area smooth, shining, most setae on margin or less than upper one-third, sparse on margins below, glabrous in concave area; elytral surface smooth, shining, punctures rather coarse, those of interstriae confused, strial and interstitial setae conspicuous, rather abundant, moderately short, and with rows of erect interstitial setae on more than posterior half, erect setae equal in length to two-thirds distance between rows; Colombia to Venezuela; *Croton guianensis*; 2.1–2.4 mm *subcribrosa* (Eggers)
- Female frons flat to feebly concave, median half on lower two-thirds glabrous, very finely reticulate, lateral and upper margins bearing a fringe of long hair to epistoma; interstitial punctures rather small, shallow, most uniseriate; sparse setae on odd-numbered interstriae 93
- 93(92). Smaller, more slender, body 2.6 times as long as wide; elytral surface smooth, shining; female frons weakly convex, glabrous area strongly reticulate, almost rugose-reticulate, tips of longest setae on upper margin capable of extending one-half to two-thirds distance to epistomal margin; Brazil (Santa Catarina); 1.4–1.6 mm *glabrata* (Schedl)
- Larger, stouter, 2.3 times as long as wide; elytral surface moderately reticulate; female frons flat, glabrous area weakly reticulate, tips of longest setae on upper margin capable of extending less than one-third distance to epistomal margin; Mexico (Morelos); *Ceiba*; 1.8–2.2 mm *retifer* Wood
- 94(91). Striae not impressed, punctures small, shallow, strial and interstitial setae short and rather abundant on posterior half, sparse, erect setae on some odd-numbered interstriae; female frons almost

CTENOPHORINI

	flat, a weak median elevation on lower half, setae restricted to dorsal fringe above upper level of eyes; Costa Rica; tree branch; 1.5–1.7 mm	<i>costaricae</i> Wood
—	Discal striae distinctly impressed, punctures rather coarse, deep; erect interstitial setae fine, rather long, rows extending to base; female frons with subcircular central half minutely granular and glabrous, median line weakly elevated, shining, higher and wider toward epistoma, row of long setae on lateral and upper margins surround granular area; Mexico (Chiapas) to Costa Rica; tree branch; 1.5–1.8 mm	<i>marginata</i> Wood
95(81).	Elytra either subglabrous or with erect rows of interstitial setae, strial and ground setae absent; small species	96
—	Strial setae present, interstitial setae abundant; some species large, pubescent	102
96(95).	Female frons ornamented by long hair, male frons convex and sparsely pubescent; erect interstitial setae in sparse rows on odd-numbered interstriae	97
—	Frons convex and sparsely pubescent in both sexes; erect rows of setae on all interstriae	99
97(96).	Elytral declivity more gradual, modestly impressed near suture, rather narrowly rounded behind; anterior half of pronotum more coarsely asperate (female not seen); Puerto Rico; 2.1 mm (Bright study in progress)	(*Puerto Rico sp.)
—	Elytral declivity steeper, evenly convex (not impressed near suture), more broadly rounded behind; pronotum more finely asperate; female frons flat to weakly concave, ornamented by long hair	98
98(97).	Female frons shallowly concave on lower half, margin on upper half ornamented by long hair; lower half of impressed area closely punctured; strial punctures rather small, interstitial punctures almost obsolete, sparse on odd-numbered interstriae; Costa Rica; <i>Ochroma</i> ; 1.2–1.3 mm	<i>ochromae</i> Wood
—	Female frons with median one-fifth just above level of antennal insertion with an oval, smooth, shining area, remaining area finely, closely punctured and ornamented by abundant hair; strial punctures moderately coarse, deep, interstitial punctures small, deep, close, uniseriate; Cuba, Dominica, Guadeloupe, Puerto Rico; 1.3–1.6 mm	<i>notata</i> (Eggers)
99(96).	Larger species; carina of interstriae 10 continued to base of declivity; minute strial setae present, interstitial setae in uniseriate rows; pronotum asperate on anterior third; Brazil (Santa Catarina); 1.5 mm	<i>morula</i> (Schedl)
—	Mostly smaller species; carina of interstriae 10 ending at level of hind coxae; strial setae obsolete	100
100(99).	Mature color black; pronotum reticulate; striae 1 not impressed, interstitial punctures sparse, setae restricted to posterior half, at least one on each interstriae, sparse; Venezuela; <i>Clusia</i> ; 1.4–1.7 mm	<i>comitabilis</i> Wood
—	Mature color brown; pronotum smooth, shining; striae 1 distinctly impressed, interstitial punctures regularly spaced, with erect setae on all interstriae to base	101
101(100).	Pronotum 1.0 times as long as wide; striae 1 on disc rather weakly impressed, punctures smaller; erect interstitial setae stout, apex blunt, shorter, each about two-thirds as long as distance between rows; Brazil (Santa Catarina); 0.9–1.0 mm	<i>minuta</i> Wood
—	Pronotum slender, 1.15 times as long as wide; striae 1 on disc distinctly impressed, punctures larger; erect interstitial setae very slender, longer, each slightly longer than distance between rows; Colombia; Leguminosae tree branch; 1.0–1.3 mm	<i>pusillima</i> Wood

SCOLYTIDAE OF SOUTH AMERICA

102(95).	Body more slender, at least 2.3 times as long as wide; striae punctures on disc in definite, identifiable rows; elytral declivity rather steep, occupying slightly less than posterior half of elytra	103
—	Body stout, less than 2.1 times as long as wide; striae punctures either in definite rows or confused with those of interstriae; elytral declivity more gradual, occupying posterior half of elytral length	117
103(102).	Pronotum widest at or behind middle; setae on pronotum and elytra shorter, longest rarely equal to more than width of one interstriae; interstitial punctures either uniseriate or confused, almost as large as those of striae; smaller species than 2.8 mm	104
—	Pronotum conspicuously wider well in front of middle; setae on pronotum and elytra unusually long, longest setae equal in length to distance from suture to striae 3; interstitial punctures uniseriate, conspicuously smaller than those of striae; larger species, more than 2.5 mm	113
104(103).	Species smaller, 1.2–1.5 mm; discal interstriae 2 and 3 with punctures uniseriate from base to base of declivity; lower frons about evenly convex, without a median carina	105
—	Species larger, 1.7–2.4 mm; discal interstriae 2 and 3 with punctures confused at least on posterior half; lower frons (or vertex in <i>limbata</i>) with a weak to moderate median carina	109
105(104).	Summit of pronotum distinctly anterior to middle, asperities on anterior slope coarser, more numerous, profile from summit to base almost straight, basal margin with a fine, raised line; elytral setae all short, without erect interstitial rows; Mexico (Nayarit); <i>Ficus</i> ; 1.2 mm	<i>nayaritensis</i> Wood
—	Summit of pronotum indefinite, at or behind middle, profile of basal half distinctly convex, basal margin poorly defined, raised line obscure; asperities small, limited area; interstitial setae with erect rows	106
106(105).	Pronotum longer than wide, with basal half mostly smooth, shining, reticulation obscure; interstriae twice as wide as striae, punctures larger; Ecuador; 2.0 mm	<i>hagedorni</i> (Schedl)
—	Pronotum as wide or wider than long, posterior half rather strongly reticulate; striae punctures smaller; interstriae three or more times as wide as a striae; smaller species	107
107(106).	Body very slender, 2.6 times as long as wide; striae punctures on disc rather coarse, each almost half as wide as interstriae; interstitial punctures almost as large as those of striae; Bolivia (Cochabamba); 1.6 mm	<i>parva</i> (Eggers)
—	Body less than 2.3 times as long as wide; striae punctures smaller, each about one-third as wide as an interstriae; interstitial punctures mostly less than half as large as those of striae; smaller species	108
108(107).	Punctures on disc of pronotum smaller; striae and interstitial ground setae short, equal in length to less than twice diameter of a striae puncture; setae on lower female frons almost obsolete; Venezuela; tree branch; 1.0–1.4 mm	<i>perpusilla</i> Wood
—	Punctures on disc of pronotum distinctly larger; striae and interstitial ground setae much longer, equal in length to more than three times diameter of a striae puncture; setae on lower female frons rather short and sparse but conspicuously present; Venezuela; Leguminosae liana; 1.3–1.5 mm	<i>crinita</i> Wood
109(104).	Frons either without an elevation or with a median elevation above upper level of eyes; discal punctures on pronotum rather coarse, deep, close, margin of punctures without a shining spot, striae punctures smaller, closer, interstitial punctures small to minute, uniseriate on basal half of disc	110

- Frons with subcarinate elevation on lower half; discal punctures on pronotum smaller, not as close, reticulation in spaces between punctures conspicuous, margin of at least some punctures with a shining spot; striae punctures on disc larger, not as close, interstriae punctures on disc almost half as large as those of striae 111
- 110(109). Frons without a median elevation; pronotum disc partly shining, reticulation reduced to almost absent; striae punctures on disc small, not as close, interstriae punctures uniseriate to declivity; Bolivia (Cochabamba); 1.7 mm *adusta* (Eggers)
- Frons with a median elevation near upper level of eyes; pronotum disc strongly reticulate; striae punctures on disc small, very close, interstriae punctures uniseriate on basal half of disc, slightly to moderately confused behind; Bolivia (Cochabamba); 1.8 mm *limbata* (Eggers)
- 111(105). Discal striae with punctures small, interstriae only slightly smaller, those on 1–4 abundant and strongly confused from base to declivity; punctures on pronotum disc smaller, closer, most with a tiny shining spot on rim; Bolivia (Cochabamba); 2.1 mm *confusa* (Eggers)
- Discal striae with punctures distinctly larger, interstriae punctures less numerous, uniseriate on at least basal half of disc 112
- 112(111). Punctures on posterior half of pronotum disc with shining spot on margins rarely visible behind summit; elytral surface near and on declivity brightly shining, punctures slightly larger, less abundant; declivital setae distinctly longer, less abundant, their length more irregular; Bolivia; 2.1 mm *ater* Eggers
- Shining spot at margin of punctures behind summit of pronotum present on almost all punctures; elytral surface near and on declivity shagreened, subshining, punctures on declivity much smaller, more abundant; declivital setae much shorter, more abundant; Venezuela; Cucurbitaceae vine, *Ficus*, *Podocarpus*; 1.9–2.4 mm *gennaea* Wood
- 113(103). Asperities larger, extending almost to middle of pronotum, punctures not extending into asperate area, lateral shining spot not consistently present, punctures slightly larger and closer near base in median area; upper declivity more uniformly convex, striae 1 and 2 reduced but recognizable; frontal carina smooth, shining; Venezuela; Cucurbitaceae vine; 1.7–1.9 mm *libida* Wood
- Asperities smaller, restricted to less than anterior one-third of pronotum length, punctures smaller, extending slightly into asperate area, each puncture with a shining spot on lateral margin, punctures not larger or closer at base near median line; upper declivity slightly flattened, punctures more uniformly small, confused, striae 1 and 2 not recognizable; frontal carina reticulate to summit 114
- 114(113). Posterior half of pronotum with sides only slightly narrower near base; discal interstriae 2 and 3 with punctures confused from base to base of declivity; longest interstitial setae about 1.5 times as long as width of a discal interstriae; Colombia, 4000 m; 2.8 mm *tolimana* (Schedl)
- Posterior half of pronotum with sides conspicuously narrower than anterior areas; discal interstriae 2 and 3 with punctures uniseriate from base to apex; interstitial setae often much longer 115
- 115(114). Pronotal asperities on anterior slope smaller, not reaching summit; punctures on disc of pronotum and disc of elytra much smaller, less numerous on pronotum, those on discal striae at least three times as wide as those of interstriae; punctures on declivity very small, in rows, striae not impressed; Colombia; "*Baccharus*" sp.; 2.4–2.8 mm *constricta* Wood
- Pronotal asperities coarser, closer, extending to summit; punctures on pronotum and elytra much larger, discal interstriae twice as wide as striae 116
- 116(115). Female frons more distinctly convex, punctured over a greater area, median, smooth, shining area smaller to obsolete, without a median fovea near center, vestiture on female frons much shorter,

- none longer than distance equal to width of an eye; mature color with basal half of pronotum and all of elytra light brown, anterior half of pronotum dark; Venezuela; liana; 2.6–3.0 mm
 *contracta* Wood
- Female frons more distinctly flattened, a distinct fovea near center; smooth, shining area much larger; conspicuous, vestiture on female frons more numerous, much longer, some setae two or three times longer than width of an eye; mature color with all of pronotum, elytral suture and sides dark, striae 1 to about 5–7 light brown; Venezuela; *Croton*; 2.7–3.2 mm *varia* Wood
- 117(102). Elytral disc occupying basal half of elytra length, punctures from base to apex abundant, close, confused, setae uniformly short, without discernible rows of longer, erect setae; pronotum with anterior two-thirds armed by numerous asperities, summit indefinite, on basal third; Bolivia; 2.3 mm *atrotibialis* (Eggers)
- Elytral disc occupying 30–60 percent of elytra length, striae punctures either in rows or obsolete and replaced by tubercles, never with dense, confused punctures 118
- 118(117). Elytral disc occupying 40–60 percent of elytra length; striae punctures larger, in discernible rows; elytra ground setae more abundant, erect setae mostly shorter 119
- Elytral disc occupying less than 30 percent of elytra length; elytral punctures either confused and striae not recognizable or striae punctures obsolete and replaced by tubercles 122
- 119(118). Strial punctures small, shallow, in definite rows from base to apex; interstriae without any tubercles, punctures small, deep, dense, confused from base to apex; elytral vestiture of abundant, short, hairlike ground cover from base to apex, at least on odd-numbered interstriae on disc with a uniseriate row of long erect setae, each seta about equal in length to combined width of two interstriae 120
- Elytral punctures either partly or entirely replaced by tubercles; striae punctures either lost or confused with those of interstriae on most of elytra length 123
- 120(119). All elytral interstriae with a row of erect bristles of about equal length; most of erect interstitial bristles slightly shorter than distance equal to width of an interstriae; Bolivia (Cochabamba); 2.3 mm (*pilifer* Plate LVI figs., Mexico) *pilosula* (Eggers)
- Erect bristles on interstriae unequal, either those on even-numbered interstriae absent or conspicuously shorter than those on odd-numbered interstriae 121
- 121(120). Odd-numbered interstriae (at least 1 and 3) each with a row of very long setae, even numbered interstriae with a row of shorter setae, each about equal in length to width of one interstriae or less; Peru; 2.6 mm *schoenmanni* Wood
- Odd-numbered interstriae each with a row of long setae, even-numbered interstriae without a row of setae 122
- 122(121). Asperities on anterior slope of pronotum extending from side to side, anterior margin feebly serrate, about 8 small serrations; ground setae on basal fourth of disc very slender, each at least 6–8 times as long as wide, those on declivity much shorter, stouter; erect interstitial bristles very sparse on all interstriae except 2; Bolivia (Cochabamba); 3.3 mm *laevicollis* (Eggers)
- Asperities on anterior slope of pronotum on median half of pronotum width, anterior margin more coarsely serrate, 12 serrations present; sparse rows of erect setae on odd numbered interstriae; Bolivia (Cochabamba); 3.3 mm *brevis* (Eggers)
- 123(119). Elytral punctures strongly confused only on basal one-fourth and sides of disc, punctures on interstriae 1–3 then become moderately tuberculate, striae punctures minutely tuberculate and mostly in rows; frons rugose-reticulate from vertex to well below upper level of eyes, rather strongly reticulate below; Venezuela; tree bole, liana; 2.7–3.5 mm *opaca* Wood

- Elytral punctures small, rather deep, strongly confused from base to apex, without any tubercles on disc or declivity, vestiture rather short, recumbent, abundant; area above eyes moderately rugose-reticulate, becoming finely reticulate below 124
- 124(123). Pronotum strongly reticulate from base to anterior margin (in areas between asperities on anterior half), asperities on anterior slope distinctly larger; striae 1–3 obscurely discernible near base of elytra; declivital setae very fine, equal in diameter to those on disc, punctures on declivity minute (diameter of each puncture equal in diameter of its seta) 125
- Pronotum more weakly reticulate on posterior half, almost smooth and shining on anterior slope, asperities on anterior slope distinctly smaller; striae 1–3 not discernible near base, punctures entirely confused 126
- 125(124). Strial punctures on discal interstriae 1–3 more distinctly indicated, continued on 1 to declivity, striae 1 deeply impressed on declivity, striae 2 more weakly impressed on lower half of declivity, punctures small, shallowly impressed; punctures on discal interstriae distinctly larger, especially near base of declivity; Brazil (Rio de Janeiro); 2.9–3.2 mm *vicina* (Eggers)
- Strial punctures on discal interstriae 1–3 obsolete before base of declivity, 1 more weakly impressed on declivity, 2 not impressed on declivity (punctures obsolete); punctures on discal interstriae near base of declivity minute; Argentina; 3.1 mm *argentinensis* (Eggers)
- 126(124). Frons more strongly, evenly convex, without a median impression or fovea; summit of pronotum only slightly behind middle, asperities on anterior slope very small, poorly formed; elytral declivity more uniformly arched, punctures on declivity about half as large as those near base of disc; Panama (Chiriqui) to Bolivia and Argentina; at light; 2.4–2.8 mm *similis* (Eggers)
- Frons more broadly convex, a weak median impression and fovea present; summit of pronotum well behind middle, asperities on anterior slope much larger, more numerous; elytral declivity somewhat flattened on its basal half, punctures near and on declivity minute, considerably smaller than those on base of disc; Argentina to Bolivia (Cochabamba); 2.9–4.0 mm *major* (Eggers)

Scolytodes jucunda Wood

Scolytodes jucundus Wood, 1977:519. Holotype ♀; Rancho Grande, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:394)

Diagnosis: Punctures on discal interstriae confused only on 2 and 3; rows of short interstitial setae usually absent on disc, present on declivity; lower frons of male with a moderate, transverse impression except on median line, female more broadly, more strongly impressed, larger.

Male: Length 3.0–3.7 mm, 2.2 times as long as wide; mature color black. Frons similar to male *glabrescens* Wood except transverse impression on lower one-third stronger, a weak transverse elevation above this elevation and on median line; upper area as in *glabrescens*, except punctures slightly larger; glabrous except sparse setae on epistoma. Pronotum about as in *glabrescens*, except punctures reduced in size and obsolete by anterior one-fourth, replaced on anterior one-fourth by rather fine asperities. Elytra similar to *glabrescens*, except strial punctures slightly larger, in almost uniseriate rows to base of declivity; interstitial punctures uniseriate except confused on 2 and 3, uniseriate rows of rather short, erect setae on lower half of declivity.

Female: Similar to male except lower two-thirds of frons broadly, subconvexly impressed to epistoma; punctures fine, close, impressed area ornamented by rather abundant, uniformly distributed, moderately long hair; pronotum without asperities, fine punctures extend to anterior margin; interstriae each with a sparse, uniseriate row of fine tubercles, setae extend to middle of disc from declivity.

Distribution: Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 403, fallen *Cecropia* leaf petioles, SLW.

Biology: As in *glabrescens*.

Notes: The above treatment was based on the type series of 11 specimens.

Scolytodes glabrescens Wood

Plate LI

Prionosceles glaber Wood, 1961:102. Holotype ♂; Summit, Canal Zone, Panama; USNM, Washington, preoccupied by Eichhoff 1868 (Synonymy and references in Wood & Bright c1992:393)

Scolytodes glabrescens Wood, 1972:152. Holotype ♂; Summit, Canal Zone, Panama; USNM, Washington, replacement name

Diagnosis: Discal interstriae 2–9 with punctures confused; male frons uniformly convex from just above

epistoma to vertex, female frons narrowly, weakly impressed on a small area; pronotum and elytra glabrous.

Male: Length 2.5–3.1 mm, 2.0 times as long as wide; color black, glabrous. Frons with area below level of antennal insertions transversely impressed, almost flat, upper area convex to vertex; surface reticulate, finely, rather closely, deeply, uniformly punctured; glabrous except for an epistomal brush of rather long, yellow hair on median two-thirds. Pronotum 1.06 times as long as wide; surface weakly reticulate, subshining, punctures small, deep, uniformly distributed, anterior one-fifth with anterior margin of punctures weakly wrinkled (subasperate); glabrous. Elytra 1.15 times as long as wide, 1.3 times as long as pronotum; striae indicated only near base, punctures very small, moderately impressed, confused with similar punctures of interstriae on 2–9; surface smooth, shining, glabrous; declivity convex, very steep.

Female: Similar to male except lower two-thirds of frons flattened to shallowly impressed, small punctures dense, vestiture on impressed area moderately abundant, rather long.

Distribution: Costa Rica to Colombia.

Colombia: 24 km E Barbosa, Antioquia, 18-VII-1970, 1200 m, No. 701, fallen *Cecropia* leaf petioles, SLW.

Biology: Parental tunnels in the basal half of fallen leaf petioles were of the cave type. The larvae expanded the parent gallery.

Notes: The Venezuelan record (Wood 1982:474) actually refers to *jucundus*. The above treatment was based on 10 specimens from Panama and 1 from Colombia. The 2 specimens from Turrialba, Costa Rica, have disappeared from my collection.

Scolytodes permagna (Eggers)

Scolytodes permagnus (Eggers), 1943:364 (*Prionosceles*). Holotype ♂; Cochabamba, Bolivia; NHMW, Wien (References in Wood & Bright c1992:397)

Diagnosis: Distinguished from *glabrescens* Wood by the much larger size; by the distinctly larger punctures on both the pronotum disc and elytral disc; and by the presence of erect interstitial setae in rows on the lower half of the declivity.

Male: Length 4.3 mm, 2.1 times as long as wide; color black. Frons similar to male *glabrescens* except punctures somewhat larger. Pronotum 1.03 times as long as wide, widest near middle; similar to *glabrescens* except asperities on anterior fourth slightly larger, punctures on disc distinctly larger. Pronotum 1.2 times as long as wide, 1.3 times as long as pronotum; elytral punctures confused from 1 to 9 except striae 1 to 3 with punctures in identifiable rows on less than basal third of disc; a few short, erect interstitial setae present on lower half of declivity from suture to interstriae 9.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Hosts: Probably *Cecropia* leaf petioles.

Notes: The above treatment was based on the male holotype from Bolivia.

Scolytodes atrata (Blandford)

Scolytodes atratus (Blandford), 1897:178 (*Prionosceles*). Lectotype ♂; Senahu, Vera Paz, Guatemala; BMNH, London, designated by Wood 1982:475 (Synonymy and references in Wood & Bright c1992:379–380)

Prionosceles atratus panamensis Wood, 1961:103. Holotype ♂; Summit, Canal Zone, Panama; USNM, Washington

Diagnosis: Allied to *glabrescens* Wood, asperities on anterior slope of pronotum definite in male, absent in female; male lower frons with a strong, transverse impression, female frons more strongly impressed; interstitial rows of setae extend to base.

Male: Length 2.5–3.3 mm, 2.1 times as long as wide; mature color very dark brown to black. Frons smooth, shining and coarsely, deeply, rather closely punctured from middle to upper level of eyes, becoming reticulate and less coarsely punctured to vertex; lower area with a broadly U-shaped impression beginning in lateral area slightly above level of antennal insertion and extending orad and across epistomal margin (obscure in Costa Rica to Panama specimens), area between arms convex (strongly protuberant in southern part of range); vestiture limited to epistomal area, conspicuous on median half. Pronotum resembling *glabrescens*, weakly reticulate, subshining, finely punctured on basal two-thirds, declivous and finely asperate on anterior one-third, punctures reduced and becoming obsolete well before anterior margin; glabrous. Elytra resembling *glabrescens*, striae 1 distinctly, others weakly impressed, punctures small, close, distinct; interstriae three to four times as wide as striae, smooth, shining, punctures minute, in uniseriate rows, replaced by fine tubercles near declivity. Declivity broadly convex, steep; sculpture as on disc except tubercles extend to apex. Vestiture of rows of fine, erect hair from middle of disc to apex, each seta equal in length to half distance between rows.

Female: Similar to male except frons broadly, rather strongly impressed on lower two-thirds to epistoma, subconcave area closely, moderately, uniformly punctured and with fine, rather short hair; elevated subcarinate callus on median line from epistoma to level of antennal insertion (this callus flattened and expanded into a shining, impunctate area in specimens from Costa Rica to Panama).

Distribution: Mexico (Veracruz) to Panama. Not seen from South America, but almost certainly will be found in Colombia and Venezuela.

Hosts: *Cecropia peltata* (etc.?) leaf petioles (fallen).

Biology: As described for *glabrescens*.

Notes: Specimens from Mexico to Honduras are noticeably larger and anatomically distinct; those from Costa Rica and Panama are smaller. Specimens from Nicaragua were not seen but probably exhibit intergradation between the races.

Scolytodes festa Wood

Scolytodes festus Wood, 1977:519. Holotype ♀; Piedras Blancas 11 km W Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:392)

Diagnosis: Distinguished from *atratus* (Blandford) by the abruptly impressed lower male frons, a subacute transverse carina below (orad) this impression; female with weak asperities on anterior slope of pronotum; and female interstitial setiferous punctures granulate on declivity.

Male: Length 2.7–3.0 mm, 2.1 times as long as wide; mature color very dark brown to black. Upper frons similar to *atratus*; a subcarinate, straight, transverse elevation ending laterally in an indefinite tubercle, a moderate, transverse impression above elevation, slope below elevation almost flat to epistomal margin, a tuft of long hair on median half of epistoma. Pronotum about as in *atratus* except punctures slightly larger, a few fine setae in anterolateral areas. Elytra resembling *atratus* except striae obscurely impressed, interstitial punctures slightly larger, granules on and near declivity reduced to obscure, erect setae equal in length to distance between rows, setae on some lateral rows attain base.

Female: Similar to male except frons rather narrowly flattened to feebly concave on lower two-thirds, punctures fine, moderately close, setae moderately long, less numerous than in *atratus*; anterior slope of pronotum with asperities reduced to obsolete, punctures attain anterior margin; most rows of interstitial setae attain base.

Distribution: Colombia: Piedras Blancas 11 km W Medellin, Antioquia, 17-VII-1970, 2300 m, No. 691, fallen *Cecropia* leaf petioles, SLW.

Biology: As described for *glabrescens*.

Notes: The above treatment was based on the type series of 7 specimens.

Scolytodes suturalis Wood

Scolytodes suturalis Wood, 1977:521. Holotype ♂; El Laurel Experimental Farm 12 km SW Caracas, Venezuela; USNM, Washington (References in Wood & Bright c1992:399)

Diagnosis: Distinguished from *festus* Wood by the more strongly elevated male transverse epistomal elevation; and by the larger, more extensively distributed interstitial tubercles.

Male: Length 2.3–2.8 mm, 2.1 times as long as wide; mature color very dark brown to black. Frons as in *festus* except transverse carina on lower frons more narrowly (on longitudinal body axis), much more strongly elevated, frons more closely punctured. Pronotum as in *festus* except punctures distinctly smaller. Elytra resembling *festus* except striae punctures smaller (rows irregular), interstitial punctures at least partly granulate to base, granules slightly larger, setae slightly shorter.

Female: Similar to female *festus* except frons much more extensively impressed and punctured; anterior slope of pronotum finely asperate (almost equal to male).

Distribution: Venezuela: El Laurel Experimental Farm 12 km SW Caracas, 1-V-1970, 1300 m, No. 461, fallen *Cecropia* leaf petioles, SLW.

Biology: As in *glabrescens*.

Notes: The above treatment was based on the type series of 5 specimens.

Scolytodes imitans (Eggers)

Plate LII

Scolytodes imitans (Eggers), 1940:136 (*Prionosceles*). Holotype ♀; Guadeloupe (Trois-Rivieres); MNHN, Paris (References in Wood & Bright c1992:393)

Diagnosis: Distinguished from *maura* (Blandford) by the almost smooth pronotum (reticulation very obscure); by the more narrowly flattened female frons; and by the presence of setiferous interstitial granules.

Male: Length 1.6–2.0 mm, 2.2 times as long as wide; mature color dark brown. Frons rather broadly evenly convex from vertex to a weak, transverse impression at level of antennal insertion, epistomal area simple; surface reticulate, setae fine, sparse, moderately long on lower half. Pronotum 1.0 times as long as wide, surface almost smooth, shining, punctures very small, except anterior one fourth finely, obscurely asperate, punctures attaining anterior margin; glabrous except for about 4–8 setae near lateral and anterior margins. Elytra 1.2 times as long as wide, 1.4 times as long as pronotum; striae 1 distinctly, others feebly impressed, punctures rather small, distinct; interstriae three times as wide as striae, surface smooth, shining, each with a uniseriate row of fine, setiferous granules from base to apex. Declivity broadly convex, steep; sculpture similar to disc. Vestiture of uniseriate rows of moderately stout, erect setae from base to apex on all interstriae, each very slightly longer than distance between rows.

Female: Similar to male except lower half of frons broadly flattened, finely, closely punctured, and ornamented by moderately abundant, long hair; pronotal asperities reduced to rather obscure; some (to most) granules on discal interstriae obsolete, replaced by small punctures. Female from Peru with frontal impression slightly less extensive, punctures not as close, setae less abundant, almost certainly same species.

Distribution: Guadeloupe Island and Venezuela to Peru and Bolivia.

Bolivia: "Bolivia."

Peru: Pucallpa, 2-X-1954, E.I. Schlinger, E.S. Ross.

Venezuela: Baranchas, Barinas, 1-X-1970, 150 m, No. 22, *Cecropia*, SLW; Campamento Rio Grande, 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, *Cecropia* leaf petioles, No. 526, SLW; 40 km SE Socopo, Barinas, 26-I-1970, 150 m, No. 251, *Cecropia* leaf petioles, SLW.

Hosts: *Cecropia* leaf petioles (fallen).

Biology: The basal 5 cm of a petiole was infested; habits resemble those of *glabrescens* Wood.

Notes: The above treatment was based on 1 female homotype from Peru and 39 specimens from Venezuela.

Scolytodes brasiliensis (Eggers)

Plate XLIX

Scolytodes brasiliensis (Eggers), 1929:89 (*Prionosceles*). Holotype ♂; Blumenau, [Santa Catarina] Brazil; USNM, Washington; nec *braziliensis* Schedl 1935:274 (References in Wood & Bright c1992:389)

Diagnosis: Distinguished from *maura* (Blandford) by the stouter body form; by the more strongly developed asperities on the anterior third of the pronotum; and by the less strongly impressed striae and interstitial punctures on both disc and declivity.

Male: Length 2.0 mm, 1.9 times as long as wide; color black. Frons not clearly visible on type, very similar to *maura*. Pronotum 0.97 times as long as wide; similar to *maura* except asperities on anterior third of pronotum length distinctly larger, punctures on posterior areas not attaining anterior margin; punctures on disc larger; glabrous except sparse setae near anterior margin. Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; disc occupying basal half of elytra length; striae not impressed, punctures small, very shallow; interstriae three times as wide as striae, smooth, shining, punctures smaller than those of striae, regularly placed. Declivity broadly convex, steep; sculpture about as on disc, punctures very small, very shallow, most interstitial punctures replaced by a very minute granule. Vestiture of rows of minute strial hair, and rows of erect interstitial setae, each seta very slender, almost hairlike, longest equal in length to distance between rows (very slightly longer than in *maura*).

Distribution: Brazil: Blumenau [Santa Catarina].

Hosts: The resemblance of *maura* is such that the host of this species should be fallen *Cecropia* leaf petioles.

Notes: The above treatment was based on the male holotype of *Prionosceles brasiliensis* Eggers.

Scolytodes brasiliana Wood

Scolytodes brasilianus Wood, 1988:32. Holotype ♂; Brazil; NHMW, Wien, replacement name, automatic (References in Wood & Bright c1992:389)

Hexacolus brasiliensis Schedl, 1935:274. Holotype ♂; Brazil; NHMW, Wien, preoccupied by Eggers 1928:89

Diagnosis: Distinguished from *maura* (Blandford) by the larger punctures on the discal striae, with striae 1 impressed on less than the posterior half of the disc; by the radically different male frons, as described below; and by the larger size.

Male: Length 2.4 mm, 2.1 times as long as wide; color very dark brown. Frons with a transverse impression on median half one-third distance from epistoma to upper level of eyes, impression fading and expanding slightly orad, lateral area from end of impression to below antennal insertion rather coarsely rugose; lower area rather coarsely irregularly, somewhat rugose punctate; area above impression convex, strongly reticulate, punctures coarse, close, deep; vestiture hairlike, sparse, short, except longer near epistoma. Pronotum 1.0 times as long as wide; declivous on anterior third, with small isolated asperities; entire surface rather strongly reticulate, including between asperities, punctures on posterior half small, rather shallow, moderately close; glabrous except for a few, short setae at anterior margin. Elytra 1.3 times as long as wide, 1.5 times as long as pronotum;

striae 1 moderately impressed on posterior half of disc and upper declivity, others not impressed, punctures moderately coarse, deep, spaced within a row by diameter of a puncture; interstriae about twice as wide as striae, surface smooth, shining, punctures uniseriate, about half as large as those of striae, a few near declivity very slightly granulate. Declivity broadly convex, steep; striae 1 distinctly impressed on basal half; interstriae narrower than on disc, punctures replaced by uniseriate rows of very small granules. Vestiture consisting of uniseriate rows of erect interstitial setae on and near declivity, each seta equal in length to two-thirds distance between rows, spaced within a row by length of a seta.

Distribution: Brazil.

Brazil: Camborea, Parque Unipaias, Santa Catarina, Atlantic Forest, 31-XII-2001, *Cecropia* petiole, C.A.H. Flechtmann; Jaragua do Sul, Malwee Park, Santa Catarina, 7-I-1999, *Cecropia* petioles, C.A.H. Flechtmann; Tres Lagoas, MS, International Paper, Horto Barra de Moreda, 9-XII 2000, riparian forest, fallen *Cecropia* forest, C.A.H. Flechtmann;

Hosts: *Cecropia* leaf petiole.

Notes: The above treatment was based on the male holotype and 6 other specimens from Brazil.

Scolytodes maura (Blandford)

Plate LIV

Scolytodes maurus (Blandford), 1897:178 (*Prionosceles*). Lectotype ♂; Pantaleon, Guatemala; BMNH, London, designated by Wood 1982: 474 (Synonymy and references in Wood & Bright c1992:394–395)

Prionosceles medius Eggers, 1928:89. Lectotype ♀; E Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:19 (References in Wood & Bright c1992:395). *New synonymy*

Hexacolus ellipticus Eggers, 1934:80. Holotype ♂; Turrialba, Costa Rica; DEI, Munchenberg

Prionosceles ingae Blackman, 1943:383. Holotype ♀; La Esperanza, Colombia; USNM, Washington (References in Wood & Bright c1992:393). *New synonymy*

Diagnosis: Distinguished from *imitans* (Eggers) by the moderately reticulate pronotum, with asperities almost obsolete; by the more broadly, shallowly concave female frons; and by the absence of interstitial granules.

Male: Length 1.6–2.1 mm, 2.0 times as long as wide; mature color very dark brown to almost black. Resembling *imitans* except frons more strongly convex, punctures much smaller; pronotum finely reticulate, asperities greatly reduced, almost obsolete; interstitial punctures uniseriate, never replaced by a granule; interstitial setae slightly shorter than distance between rows.

Female: Resembling female *imitans* except frons broadly, shallowly concave, pronotum reticulate to anterior margin (no suggestion of asperities), otherwise as in male.

Distribution: Dominica and Mexico (Veracruz) to Bolivia, Colombia, and Venezuela (Caracas).

Bolivia: Ostbolivia [F. Woytkowski].

Colombia: La Esperanza.

Venezuela: El Laurel Experimental Farm 12 km SW Caracas, 1-V-1970, 1300 m, No. 510, fallen *Cecropia* leaf petioles, SLW.

Biology: As in *imitans*.

Notes: The above treatment was based on 5 specimens from Venezuela and on 97 from Mexico to Panama. The male lectotype of *maurus* was examined; also the female holotype of *Prionosceles medius* from Bolivia. The female holotype and allotype of *ingae* from Colombia were examined; they are clearly of the southern variant of *maurus*, with moderately large punctures on the pronotum disc.

Scolytodes gracilis Schedl

Scolytodes gracilis Schedl, 1976:61. Holotype ♀; Corcovado, Guanabara, Brazil; NHMW, Wien (References in Wood & Bright c1992:393)

Hexacolus laevigatus Schedl, 1962:98. Holotype ♀; Santa Maria, Misiones, Dep. Concept., Argentina; NHMW, Wien, preoccupied by Ferrari 1867:77 (References in Wood & Bright c1992:394).

New synonymy

Scolytodes laevigatulus Wood, 1988:33. Holotype ♀; Santa Maria, Misiones, Dept. Concept., Argentina; NHMW, Wien, replacement name (References in Wood & Bright c1992:394). *New synonymy*

Diagnosis: Distinguished by the reticulate pronotum and elytra; and by the pair of longitudinal carinae on the female frons, with crests of carinae narrowly rounded, shining, not acute.

Female: Length 1.7 mm, 2.6 times as long as wide; color dark reddish brown. Frons with median third on lower half smooth, brightly shining, impunctate, lateral margins of this area distinctly elevated, shining crests narrowly rounded (not acute); upper half and sides lateral to carinae flattened, shining, closely, rather finely, uniformly punctured and ornamented by rather abundant, fine, long hair, longest setae at dorsal margin capable of extending about two-thirds distance toward epistoma. Pronotum 1.06 times as long as wide; surface reticulate, punctures fine, rather close, extending to anterior margin; moderately declivous on anterior third, with a few very low, transverse wrinkles; glabrous except 2 setae on anteriolateral angles. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures rather small, interstriae three times as wide as striae, uniformly reticulate, punctures small, about two-thirds as large as those of striae, uniseriate. Declivity broadly convex, steep; about as on disc. Glabrous.

Distribution: Argentina to southern Brazil.

Argentina: Misiones; Santa Maria, Concepcion, X-1946, M.J. Viana.

Brazil: Corcovado, Guanabara (R. de J.), VIII-1962 to IX-1969, Alvarenga & Seabra; Nova Teutonia, Santa Catarina, 27°11'B, 52°23'L, 300–500 m, VIII-1965, F. Plaumann.

Notes: The above treatment was based on the female holotype of *Scolytodes gracilis* Schedl from Brazil and on the female holotype (from Argentina) of *Hexacolus laevigatus* Schedl. The elytral reticulation on the type and paratypes of *laevigatus* is less obvious but is clearly evident on the posterior disc near the suture. These 2 names are objective synonyms of one another.

Scolytodes minor (Eggers)

Scolytodes minor (Eggers), 1928:89 (*Prionosceles*). Lectotype ♀; E Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:20 (References in Wood & Bright c1992:395)

Diagnosis: Female frontal carinae widely separated, extending from level of antennal insertions dorsad half distance to upper level of eyes; interstitial bristles also distinctive.

Female: Length 1.7 mm, 2.1 times as long as wide; color dark reddish brown. Frons with a pair of widely separated, strong carinae extending from level of antennal insertions dorsad about two thirds distance toward upper level of eyes, surface smooth, shining, sparsely, finely punctured; vestiture very sparse above, mostly below level of antennal insertions, inconspicuous. Pronotum 0.93 times as long as wide; summit indefinite, about one-third pronotum length from base; basal third finely reticulate, very finely, moderately punctured; more than anterior half very finely, rather closely asperate, subreticulate between asperities; vestiture of very fine, short, moderately abundant hair (mostly abraded on posterior half of type). Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures small, distinct, shallow; interstriae about four times as wide as striae, almost smooth, shining, punctures very shallow, almost as large as those of striae, uniseriate. Declivity broadly convex, steep; sculpture about as on disc. Vestiture of rows of erect, rather stout, interstitial bristles in uniseriate rows from base to apex, each blunt bristle as long as distance between rows, spaced within a row on disc by length of a bristle, by one-half length of a bristle on declivity.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the female holotype from Bolivia.

Scolytodes guyanaensis (Schedl)

Plate LII

Scolytodes guyanaensis (Schedl), 1937:13 (*Erineophilus*). Syntypes ♀ ♂; NW District, Guiana; BMNH, London, and NHMW, Wien (References in Wood & Bright c1992:393)

Hexacolus nardus Schedl, 1976:62. Holotype ♂; "Brazil" [probably French Guyane]; NHMW, Wien (References in Wood & Bright c1992:395). *New synonymy*

Diagnosis: Distinguished from *swieteniae* (Blackman) by the absence of an oral continuation of the crest of the female frontal elevation; by the yellowish brown color; and by the presence of rows of erect interstitial setae on odd-numbered declivital interstriae, each seta about equal in length to one half width of an interstriae.

Male: Similar to female except frons convex, without a median elevation or a conspicuous brush of hairlike setae.

Female: Length 1.4–1.7 mm, 2.2 times as long as wide; color yellowish brown or pale reddish brown, except anterior one-fourth of pronotum dark. Frons somewhat flattened to vertex, median line of flattened area with a

low, double-crested median elevation ending in a sub-tuberculate, low elevation just above epistomal margin, subconcave lateral areas smooth, shining, a few small punctures occasionally present; area above upper level of eyes flattened and ornamented by a dense brush of long hair, tips of some setae attain level of antennal insertions, median one-third of epistomal margin with a small brush of hair. Pronotum 1.0 times as long as wide; anterior half closely, moderately asperate, asperities much wider than normal, a few small granules continuing in median area to base; posterior areas strongly reticulate, punctures mostly replaced by minute, shining spots or by minute granules; subglabrous. Elytra 1.2 times as long as wide, 1.2 times as large as pronotum; striae feebly impressed, punctures very minute, distinctly impressed, uniseriate; interstriae about five times as wide as striae, smooth, brightly shining, punctures minute (about one-half as large as those of striae), uniseriate. Declivity convex, rather steep; interstriae 1 moderately impressed, others as on disc; glabrous.

Distribution: Venezuela to Suriname and Brazil.

Brazil: Brazil, 30-VI-1971, Andiroba lumber, lot 71-10393, T. Tinkham.

Guiana: NW District, III-1934, *Swietenia* bark, F.A. Squire.

Suriname: Suriname 1961, No. 895.

Venezuela: Campamento Rio Grande 35 km E Palmar, Bolivar, 12-VI-1970, 1200 m, *Carapa guianensis*, SLW.

Hosts: *Carapa guianensis*, *Swietenia* sp.

Biology: Breeds in phloem of bole.

Notes: The above treatment was based on 1 specimen from Brazil, 2 from Guiana, 1 from Suriname, and 101 from Venezuela, 1 of which I compared to the original Schedl series. The male holotype of *Hexacolus nardus* Schedl was examined and was compared to my series, and is of this species.

Scolytodes ommatea Wood

Plate LIV

Scolytodes ommateus Wood, 1971:15. Holotype ♀; Carton de Colombia forest 8 km S Colonia (near Buenaventura), Valle de Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:396)

Diagnosis: Eyes separated above by less than one-third width of an eye; female frons subglabrous, a transverse carina above middle.

Male: Similar to female except transverse carina on frons absent.

Female: Length 1.9–2.2 mm, 2.6 times as long as wide; color reddish brown. Frons with eyes separated above by less than one-third width of an eye, a short transverse carina slightly above middle, a rather strong, transverse impression from carina to epistomal margin, surface strongly reticulate to vertex, punctures small, shallow, not close, a few inconspicuous hairs on lower half. Pronotum 1.1 times as long as wide; surface reticulate, punctures rather small, moderately close, deep;

anterior one third moderately declivous, punctures extend to anterior margin, no indication of asperities. Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; striae 1 weakly impressed, others not impressed, punctures moderately coarse, rather deep; interstriae twice as wide as striae, punctures rather coarse, deep, slightly smaller than those of striae. Declivity shallowly subsulcate between left and right interstriae 3; striae 1 much more strongly impressed, punctures reduced, obscure, punctures on 2 and 3 greatly reduced in size; interstitial punctures on 2 and 3 replaced by small tubercles. Vestiture restricted to declivity in lateral areas, to middle of disc near suture, consisting of striae hair (length up to twice as great as diameter of a striae puncture) and interstitial hair of size of that of striae, plus erect, longer rows, longest setae slightly shorter than distance between rows.

Distribution: Colombia: Carton de Colombia forest 8 km S Colonia (near Buena Ventura), Valle de Cauca, 9-VII-1970, 30 m, No. 624, *Clusia*, SLW.

Biology: Boring in phloem of a broken branch.

Notes: The above treatment was based on the type series of 97 specimens.

Scolytodes parallela (Schedl)

Scolytodes parallelus (Schedl), 1962:99 (*Hexacolus*). Holotype ♀; Venezuela; NHMW, Wien (References in Wood & Bright c1992:397)

Diagnosis: Female frons transversely impressed on lower two-thirds, surface from epistoma to upper level of eyes somewhat obscurely micropunctate, vestiture sparse, fine, uniformly distributed; body very slender, 2.7 times as long as wide, pronotum 1.2 times as long as wide; pronotum and elytra glabrous.

Female: Length 1.7 mm, 2.7 times as long as wide; color black. Frons rather strongly, transversely impressed from epistoma about two-thirds distance to upper level of eyes (longitudinally, moderately concave, transversely almost flat), surface closely, rather obscurely micropunctured from epistoma to upper level of eyes; vestiture in impressed area of uniformly distributed, very fine, long hair of moderate abundance. Pronotum 1.2 times as long as wide; declivous and moderately asperate on anterior 40 percent, summit indefinite, anterior to middle; posterior areas finely, strongly reticulate, punctures minute, very shallow, moderately close; glabrous. Elytra 1.8 times as long as wide; striae not impressed, punctures very small, most distinctly impressed; interstriae four or more times as wide as striae, almost smooth (some minute wrinkling), punctures very small (most smaller than those of striae), uniseriate. Declivity rather narrowly convex, steep; sculpture about as on disc, all punctures slightly smaller and deeper than on disc. Vestiture absent on disc; declivity with a few very minute striae and interstitial hairlike setae.

Distribution: Venezuela: "Venezuela, Moritz," presumably taken at Colonia Tovar, Aragua, near the Moritz home.

Notes: The above treatment was based on the female holotype from Venezuela.

Scolytodes majula Wood, n.n.

Scolytodes majula Wood: Holotype ♀; Cochabamba, Bolivia; USNM, Washington, replacement name, automatic, for *Scolytodes maja* Wood 1988:33, present designation

Scolytodes major Wood, 1988:33. Holotype ♀; Cochabamba, Bolivia; USNM, Washington, replacement name, automatic, preoccupied by Eggers, 1928:86 (References in Wood & Bright c1992: 394)

Scolytodes major Eggers, 1943:361. Holotype ♀; Cochabamba, Bolivia; USNM, Washington, preoccupied by Eggers 1928:86

Diagnosis: Distinguished from *laevigata* Ferrari by the larger size; by the smooth, shining pronotum, with smaller punctures; and by the smaller strial and interstitial punctures on both striae and interstriae on disc and declivity.

Female: Length 3.1 mm, 2.3 times as long as wide; color black. Frons similar to *laevigata* except very slightly more strongly, more broadly impressed from epistoma to upper level of eyes, punctures in impressed area much smaller and more numerous, almost glabrous. Pronotum 1.06 times as long as wide; surface smooth, shining, weakly reticulate on basal third, punctures minute, rather sparse, continued to anterior margin; glabrous except for two bristles near anterior margin in sublateral areas. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; surface smooth, shining, striae not impressed, punctures very small, distinct, shallow; interstriae six or more times as wide as striae, punctures minute, about one-third as large as those of striae, uniseriate on basal half of disc, moderately confused on posterior half of 2-4. Declivity broadly convex, steep; strial punctures slightly larger and deeper than on disc, interstitial punctures slightly confused.

Distribution: Bolivia: Cochabamba (Germain), H. Donickier, 1907.

Notes: The above treatment was based on the female holotype that is part of the Eggers material in the USNM, Washington.

Scolytodes laevigata Ferrari

Scolytodes laevigatus Ferrari, 1867:77. Syntypes 2 ♂♂; Colombia; NHMW, Wien (References in Wood & Bright c1992:394)

Diagnosis: Distinguished from *trispinosa* Eggers by the feebly elevated epistoma that lacks a median callus; punctures on elytral declivity smaller; those on interstriae confused.

Female: Length 2.5 mm, 2.3 times as long as wide; color very dark brown. Frons on median two-thirds flattened to upper level of eyes, epistoma weakly elevated (without a median callus); surface reticulate, very sparsely, finely punctured, most punctures near epistoma; subglabrous, very sparse setae, minute above, longer near epistoma. Pronotum 1.0 times as long as wide; surface reticulate, punctures very small, not close, punctures

extend to anterior margin (no indication of asperities); glabrous. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; striae not impressed, punctures small, in rows; interstriae four or more times as wide as striae, punctures slightly smaller than those of striae, uniseriate except confused on 3. Declivity convex, steep; punctures smaller than those on disc, strial punctures uniseriate, interstitial punctures confused. Vestiture restricted to declivity, of minute, sparse interstitial hair.

Distribution: Colombia to Panama.

Panama: Boquette, 11-12-XI-1967, 4000 ft., G. Small. Colombia: "Colombie."

Notes: The male syntypes were examined. The above treatment was based on 1 female from Panama. In 1867 when this species was named, Panama was part of Colombia. It is entirely possible that the type locality is now part of Panama.

Scolytodes ageratinae Wood, n. sp.

Scolytodes ageratinae Wood: Holotype ♀; Cerro de la Muerte, Cartago, Costa Rica; USNM, Washington, designated below

Diagnosis: Distinguished from *laevigata* Ferrari by the slightly smaller size; by the black color and more slender body form; by the feebly convex area on the female frons above the level of antennal insertion, and fewer punctures below; by the more numerous impressed irregular lines on the elytral disc; and by other features described below.

Male: Similar to female except frons more strongly, evenly convex from epistoma to vertex, with fewer, shorter setae at epistomal margin; abdominal tergum 8 dark, pubescent, separated from 7 by a distinct suture.

Female: Length 2.3 mm, 2.4 times as long as wide; color black. Frons flat to feebly concave from epistoma to level of antennal insertion, area above level of antennal insertion more narrowly flat to upper level of eyes; surface reticulate, punctures sparse, minute above level of antennal insertion, half of those below slightly larger; epistomal lobe slightly larger and with setae slightly longer, confused; antennal club small, somewhat oval, sutures indicated. Pronotum 1.02 times as long as wide; widest slightly behind middle, sides moderately arcuate, rather broadly rounded on unarmed anterior margin; anterior slope gradual; surface rather strongly reticulate, punctures very sparse, not close; glabrous, sparse short setae on lateral margins. Elytra 1.6 times as long as wide, 2.0 times as long as pronotum; striae not impressed, punctures small, shallow, in rows from base to near base of declivity; surface mostly smooth, shining with many irregular impressed lines, interstitial punctures about half as large as those of striae, mostly in rows to base of declivity. Declivity moderately steep, convex; sculpture similar to disc, punctures more uniformly very small, most confused. Glabrous.

Distribution: Costa Rica (Cartago).

Type material: The female holotype, male allotype, and 38 paratypes were taken at Cerro de la Muerte,

Cartago, Costa Rica, 6-IV-2002, 2800 m, *Ageratina* cf. *ixiocladon* (Asteraceae), K. Nishida. The holotype, allotype and paratypes are in the U.S. National Museum, Washington.

Scolytodes tucumani Wood, n. sp.

Scolytodes tucumani Wood: Holotype ♀; 21 km W Tucuman, Tucuman Prov., Argentina; USNM, Washington, designated below

Diagnosis: Distinguished from *laevigata* Ferrari by the smaller size; by the narrower median callus on the lower frons; and by the larger strial punctures.

Female: Length 2.1 mm, 2.6 times as long as wide; mature color probably dark brown. Frons resembling *laevigata*, flattened on a slightly smaller area, epistoma more weakly elevated closer to margin, a narrow, median callus extending dorsad from epistomal elevation to slightly above level of antennal insertion; surface reticulate, sparse punctures near margins of median callus, setae sparse, short on punctured area. Pronotum 1.0 times as long as wide; surfaces more shining, otherwise about as in *laevigata*. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures moderately large, rather shallow; interstriae about three times as wide as striae, smooth, shining, punctures small, uniseriate, about one-third as large as those of striae, uniseriate. Declivity rather narrowly convex, steep; punctures smaller than on disc, uniseriate; glabrous.

Distribution: Argentina (Tucuman).

Type material: The female holotype was taken 21 km W Tucuman, P. Tucuman, 18-X-1968. The holotype is in the U.S. National Museum, Washington.

Scolytodes trispinosa Eggers

Scolytodes trispinosa Eggers, 1934:80. Holotype ♀; Amatan, Brazil; USNM, Washington (Synonymy and references in Wood & Bright c1992:400)

Scolytodes elongatus Schedl, 1935:273. Holotype ♀?; Brazil; NHMW, Wien (Synonymy and references in Wood & Bright c1992:400)

Diagnosis: Distinguished from *laevigata* Ferrari by the very different female frons as described below; and by the larger, almost uniseriate elytral punctures.

Female: Length 2.5 mm, 2.3 times as long as wide; color very dark brown. Frons shallowly impressed on lower two-thirds of median half (very shallowly concave near middle); a shining, weakly elevated, impunctate callus on median one-third from epistomal margin to level of antennal insertions; a few fine punctures in impressed area; sparse, short, inconspicuous hairlike setae in punctured area. Pronotum 1.0 times as long wide; punctures distinctly larger than in *laevigatus*; anterior slope with no hint of asperities. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; striae not impressed, punctures very small, shallow, in rows (slightly larger than in *laevigatus*); interstriae up to six times as wide as striae, punctures minute, shallow, mostly uniseriate (slight confusion on 2 and 3). Declivity rather

broadly convex, steep; strial punctures very small, in distinguishable rows, interstrial punctures on 1–3 very slightly confused; glabrous.

Distribution: Brazil: “Brasilien”; Nova Teutonia, Santa Catarina, 4-V-1950, F. Plaumann.

Notes: The above treatment was based on 1 female from Brazil that had been identified by Schedl as his *elongatus* and which I compared in 1980 to his series of that species and to his specimens of *trispinosus* Eggers (named from Mexico). On the basis of these comparisons *elongatus* was placed in synonymy (Wood 1979:136). It now appears that this proposal was premature and that a complex of very closely related species exists that is in need of review. The cotype of *medius* Eggers appears to be a male in this complex and, might be conspecific with my female from Brazil that was identified by Schedl as *elongatus*.

Scolytodes spp.

In a loan of type material received from MNHN, Paris, were the holotypes of *Scolytodes discedens* Eggers = *discriminata* Wood (♂), *S. glaber* Eggers = *glaberimus* Wood (♂), and *S. media* Eggers = *medialis* Wood (♀), all of about the same size (2.0 mm), form (2.2 times as long as wide), color and other details. Three males in my collection are of the same locality. All six specimens exhibit minor variations in details of surface sculpture but could all be the same species. More material containing both sexes is needed to determine whether 1 or 3 species are represented.

Two distinctly different members of this *laevigata* complex, represented by their unique holotypes are: (1) *S. longipennis* Eggers (♂), 2.4 mm, 2.7 times as long as wide, punctures on pronotum and elytra minute to obsolete, and glabrous; and (2) *S. aequipunctata* Eggers (♂), 2.9 mm, 2.16 times as long as wide.

All of the 8 specimens mentioned above were taken at Cochabamba, Bolivia.

Scolytodes peruana Wood, n. sp.

Scolytodes peruana Wood: Holotype ♀; Chachapoyas, Dep. Amazonas, Peru; USNM, Washington, designated below

Diagnosis: Remotely allied to *canalicula* Wood, antennal scape ornamented by a conspicuous tuft of long hair; female frons with an elevated callus on median one-fifth of lower half, its surface ornamented by large, shallow punctures.

Male: Similar to female except reticulate, subglabrous frons evenly convex.

Female: Length 2.6–3.1 mm, 2.3 times as long as wide; mature color dark brown. Frons moderately convex from epistoma to vertex, reticulate above, finely, very closely punctured from level of antennal insertions almost to upper level of eyes except median one-fifth of lower half with a distinct, low elevation, elevation ornamented by large, shallow, shining punctures (in a honeycomb

hexagonal pattern); vestiture of fine, rather abundant hair almost to upper level of eyes except glabrous on central elevation; scape ornamented by a tuft of long yellow hair. Pronotum 1.0 times as long as wide; surface reticulate, punctures moderately large, rather close, extending to anterior margin (without any indication of asperities). Elytra 1.5 times as long as wide; striae 1 feebly, others not impressed, punctures moderately coarse, rather deep; interstriae twice as wide as striae, surface obscurely reticulate, punctures small, rather close, moderately confused except uniseriate on and near declivity. Declivity broadly convex, steep; punctures similar to but smaller than on disc. Vestiture obsolete, except lower declivity with minute, sparse interstitial hair.

Distribution: Peru (Amazonas).

Type material: The female holotype, male allotype, and 4 female paratypes were taken at Chachapoyas, Dep. Amazonas, 10-VIII-1938, 2000 m, F. Woytkowski. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Scolytodes boliviana Eggers

Scolytodes bolivianus Eggers, 1928:86. Lectotype ♂; Cochabamba, Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:7 (References in Wood & Bright c1992:389)

Diagnosis: This species is not in the above key. It was based on 3 specimens from Cochabamba, Bolivia, 1 of which was deposited in that part of the Eggers Collection that reached the USNM, Washington, and 1 from Amatan (Mexico), the latter a probable error in designation of the country of origin. The male at the USNM, Washington, appears allied to *canaliculus* Wood, but it is not closely related. The elytral sculpture, described below, distinguishes *boliviana* from all other known species.

Male: Length about 2.7 mm, about 2.2 times as long as wide; color yellowish brown (callow[?]). Frons moderately convex, an obscure callus on lower third; surface reticulate on lower two thirds, almost smooth, shining above upper level of eyes (damaged), punctures fine, rather close on lower half, glabrous above, sparse setae near epistoma. Pronotum wider than long (perhaps 0.95 times as long as wide; much of anterior third missing); surface finely reticulate, finely, moderately punctured from base apparently to anterior margin; glabrous. Elytra 1.5 times as long as wide, 1.8 times as long as pronotum; striae not impressed, punctures small, shallow, obscurely indicated on basal third of disc, a few visible almost to base of declivity; interstriae more than four times as wide as striae, surface with numerous impressed lines, almost subrugose, punctures minute, confused, obscure. Declivity broadly convex, steep; striae punctures more distinctly impressed than on disc. Glabrous.

Distribution: Bolivia: Cochabamba (F. Woytkowski).

Notes: The above treatment was based on the male lectotype from Bolivia. It is presumed that the other 2 syntypes were lost with the Hamburg Museum.

Scolytodes rugulosa Eggers

Scolytodes rugulosus Eggers, 1943:362. Holotype ♂; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:399)

Diagnosis: This species is not in the above key. The type is a male that probably fits in the key somewhere between *plumericolens* Wood and *plumeriae* Wood but represents an unrelated species. Its proper placement must await discovery of the female. The carina of interstriae 10 extends beyond the level of the hind coxae, the prothoracic tibia lacks a small spine on the posterior face near the apex; and striae and interstitial setae are absent.

Male: Length 1.8 mm, 2.3 times as long as wide; color brown, anterior half of pronotum and area near suture on elytra a darker brown. Frons convex, surface reticulate, punctures small, shallow, not close; vestiture mostly restricted to lower half, sparse, fine, hairlike. Pronotum 0.95 times as long as wide; widest near base, sides on basal half almost parallel; summit near middle, anterior slope rather coarsely asperate, reticulate between asperities, serrations on anterior margin obscurely indicated; posterior half strongly reticulate, punctures rather fine, moderately close; glabrous. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures very small; interstriae smooth, shining, at least four times as wide as striae, punctures minute, mostly uniseriate on basal half of disc, weakly confused behind. Declivity rather broadly convex, steep; striae and interstitial punctures small, of equal size, mostly in rows. Glabrous.

Distribution: Bolivia: Cochabamba (Germain), H. Donickier, 1907.

Notes: The above treatment was based on the male holotype from Bolivia.

Scolytodes canalicula Wood

Plate XLIX

Scolytodes canaliculus Wood, 1977:517. Holotype ♀; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:389)

Diagnosis: A comparatively large species with the antennal scape ornamented by a conspicuous tuft of long, yellow hair; female frons moderately convex, with a large, shining, impunctate area, frontal setae sparse, long.

Male: Similar to female except frons more strongly convex, central area reticulate and punctured, setae shorter, sparse; tuft of hair on scape much smaller.

Female: Length 2.6–3.1 mm, 2.4 times as long as wide; color moderately reddish brown. Frons with upper fourth to vertex reticulate, some reticulation continuing on lateral areas to level of antennal insertions; median area on lower two-thirds (occupying median half below, median one-fourth above) smooth, shining, impunctate, sparse, rather coarse punctures above almost to upper

level of eyes, continued laterally almost to epistoma; vestiture restricted to punctured area, sparse, long. Pronotum 1.0 times as long as wide; surface reticulate, rather coarsely, somewhat closely punctured to anterior margin; no indication of asperities on anterior slope; glabrous except sparse hair near lateral margins. Elytra 1.6 times as long as wide, 1.9 times as long as pronotum; striae 1 not impressed on basal one-fourth of disc, becoming strongly, subsulcately impressed by base of declivity, others not impressed, punctures rather coarse, deep; interstriae two to three times as wide as striae, smooth, shining, punctures half as large as those of striae, uniseriate except weakly confused on 2, 4, and 6. Declivity steep, broadly convex, shallowly sulcate at striae 1 to near apex; punctures smaller than on disc. Vestiture mostly restricted to declivital interstriae; a few minute strial and interstitial setae on sides and declivity, and sparse rows of long, erect, interstitial setae on 2–9, mostly on declivity, occasionally to middle of elytra on disc or sides.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km airline NW Merida, Merida, 9-XII-1969, 2500 m, No. 177, *Clusia*, SLW.

Biology: Boring in phloem of broken branches.

Notes: The above treatment was based on the type series of 142 specimens.

Scolytodes ovalis (Eggers)

Scolytodes ovalis (Eggers), 1940:132 (*Hexacolus*). Holotype ♀?; Guadeloupe; Fleutiaux Collection, presumably now in MNHN, Paris (References in Wood & Bright c1992:396)

Diagnosis: A stout species with preasperate wrinkles on the anterior slope of the pronotum, with punctures extending to the anterior margin; the female frons is flattened on a limited area and has sparse pubescence (easily mistaken for a male). Males of *perdita* Wood are easily confused with this species.

Male: Similar to female except frons more evenly convex, setae absent, a median crest on frons from epistoma to level of antennal insertion (also visible in female).

Female: Length 1.6–1.8 mm, 2.1 times as long as wide; color brown. Frons convex, except median two-thirds of lower two-thirds flattened and densely, rather finely, uniformly punctured, fine, moderately abundant, uniformly distributed, rather long setae ornamenting punctured area; lateral and upper areas uniformly, sparsely, rather coarsely punctured. Pronotum 1.0 times as long as wide; posterior half reticulate, rather coarsely, closely, deeply punctured; anterior half transversely, subasperately wrinkled (their crest transversely rather broad), punctures of reduced size extending to anterior margin; glabrous. Elytra 1.27 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures in rows except 1 obscure on basal half of disc, punctures rather small, distinct; interstriae about three times as wide as striae, punctures two-thirds as large as those of striae, those on basal half of disc confused with those of

striae 1. Declivity rather narrowly convex, all punctures uniseriate, smaller than those on disc.

Distribution: Guadeloupe Island and Panama to Venezuela.

Venezuela: 13 km SW El Vigia, Merida, 22-X-1969, 100 m, No. 80, *Cecropia*, SLW.

Biology: Boring in phloem of *Cecropia* twig terminals.

Notes: The above treatment was based on 11 specimens from Venezuela, 1 of which I compared to the holotype of *Hexacolus ovalis* Eggers. One male and 4 female paratypes of *perditus* Wood, from Panama, are actually of this species (males of these species are easily confused with one another).

Scolytodes opacicollis (Eggers)

Scolytodes opacicollis (Eggers), 1928:90 (*Prionosceles*). Holotype ♂; E Bolivien; NHMW, Wien (References in Wood & Bright c1992:396)

Diagnosis: This species is not in the above key, but probably fits near *ovalis* (Eggers). In the absence of the female, one can only guess where this species should be placed in classification. The crest of interstriae 10 continues well beyond the level of the hind coxae; there is no small denticle near the apex of the posterior face on the protibia; strial setae are in definite rows, interstitial setae on 2 and 4 are moderately confused; pronotal asperities are small and isolated.

Male: Length 2.7 mm, 1.9 times as long as wide; color dark reddish brown. Frons broadly convex, reticulate, punctures very small, obscure. Pronotum 1.0 times as long as wide; dorsal profile rather strongly arched from base, summit indefinite; surface strongly reticulate, almost rugose reticulate, punctures on basal half very small, rather abundant, on anterior half punctures associated with minute asperities, then punctures obsolete before anterior margin; asperities all minute, isolated from one another. Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures small, shallow, distinct; interstriae about four times as wide as striae, almost smooth, subshining, punctures small, shallow, confused on 2–4. Declivity very broadly convex, steep; interstriae narrower than on disc, punctures confused (and non-setiferous) and also each with a uniseriate row of minute, setiferous granules, some granules on disc near declivity. Vestiture mostly abraded, of erect, short bristles, apparently arising only from granules (on and near declivity).

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the male holotype of *Prionosceles opacicollis* Eggers from Bolivia.

Scolytodes unipunctata (Blandford)

Scolytodes unipunctatus (Blandford), 1897:182 (*Hexacolus*). Lectotype ♀; Cubilguitz, Alta Verapaz, Guatemala; BMNH, London (References in Wood & Bright c1992:400)

Scolytodes cylindricus Schedl, 1978:297. Holotype ♀; 2000 m, Machu Picchu, Peru; NHMW, Wien (References in Wood & Bright c1992:391). *New synonymy*

Diagnosis: The female is easily distinguished by the presence of a rather large, glabrous, pyriform, median elevation on the epistoma; and by the tuft of hair on the female scape.

Male: Similar to the female except frons convex, smooth, shining, glabrous; scape without a tuft of hair.

Female: Length 2.2–2.5 mm, 2.7 times as long as wide; color very dark brown, light brown areas on pronotum and elytral declivity. Frons elongate, broadly, shallowly concave from epistoma to slightly above upper level of eyes, surface smooth, shining, densely micropunctate, bearing dense, short setae (more abundant on lower half), lower one-fifth with a median pyriform, somewhat flattened, glabrous elevation; antennal insertions displaced dorsad, slightly above middle of distance from epistoma to upper level of eyes; scape ornamented by a small tuft of long, yellow hair. Pronotum 1.1 times as long as wide; surface very finely reticulate; moderately declivous on anterior third, punctures on posterior half rather fine, of moderate abundance, slightly larger on anterior half, continued to anterior margin (no asperities or wrinkles). Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures moderately large, rather deep; interstriae three times as wide as striae, surface smooth, shining, punctures uniseriate, each less than half as large as those of striae. Declivity broadly convex, steep; sculpture about as on disc except striae and interstriae slightly narrower, interstitial punctures distinctly larger and deeper than on disc. Glabrous, except declivital interstriae with uniseriate rows of minute setae, their length less than diameter of a puncture at the their base.

Distribution: Guatemala and Costa Rica to Peru.

Peru: Machu Picchu (type of *cylindricus*).

Notes: The above treatment was based on the female holotype of *Hexacolus unipunctatus* (Blandford), from Guatemala, on the female holotype of *Scolytodes cylindricus* Schedl, from Peru, and on 1 male and 1 female from Costa Rica.

Scolytodes perplexa Schedl

Scolytodes perplexus Schedl, 1972:56. Holotype ♀; Corcovado, Guanabara, Brazil; NHMW, Wien (References in Wood & Bright c1992:397)

Diagnosis: Distinguished from the very closely allied *praeceps* Wood by the smaller size; by the shorter upper setae on the female frons that arise at or below the upper level of the eyes; by the much smaller striae and interstitial punctures; and by the more evenly convex elytral declivity.

Female: Length 2.0 mm, 2.3 times as long as wide; dark brown, much of elytral disc light brown. Frons similar to *praeceps* except setae on upper female frons not extending above upper level of eyes, their length shorter; tips capable of attaining half distance to level of antennal insertion; epistomal tubercle as in *praeceps*. Pronotum as in *praeceps* except punctures on disc slightly smaller. Elytra similar to *praeceps* except striae

punctures on disc smaller, more widely spaced (most by diameter of a puncture), interstitial punctures minute, about one-third as large as those of striae. Declivity more evenly convex than in *praeceps*, striae 1 and interstriae 1 not impressed below transverse level of interstriae 2.

Distribution: Brazil: Corcovado, Guanabara, Rio de Janeiro, X-1970, Alvarenga & Seabra.

Notes: The above treatment was based on the female holotype of *perplexa* Schedl from Brazil.

Scolytodes dissimilis Schedl

Scolytodes dissimilis Schedl, 1967:5. Holotype ♂; Ibicare, Brazil, 27°09', 51°18', 600 m; NHMW, Wien (References in Wood & Bright c1992:391)

Diagnosis: This species is not in the above key. The holotype is a male. Its position in phylogeny is uncertain because key features are concealed by glue, etc. It is placed near *perplexa* Wood because of a small, median tubercle on the epistoma; the anterior pronotum is devoid of asperities and punctures continue to the anterior margin of the pronotum; stout, erect interstitial setae occur from the middle of the declivity to the apex, each seta is as long as the distance between rows, setae are spaced slightly closer within a row (striae setae are obsolete).

Male: Length 1.3 mm, 2.2 times as long as wide; color dark reddish brown, pronotum slightly lighter. Frons convex, reticulate, punctures small, sparse; a very small, median tubercle on epistoma; a slight transverse impression on lower fourth; vestiture sparse, restricted to lower fourth, rather long. Pronotum 0.90 times as long as wide; surface reticulate, punctures rather coarse, moderately close, extending to anterior margin; glabrous, except for a few setae at margins. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures moderately coarse, spaced in row by diameter of a puncture; interstriae twice as wide as striae, surface smooth, shining, punctures small, uniseriate. Declivity rather broadly convex, steep; sculpture about as on declivity. Vestiture of stout, erect interstitial setae on declivity and posterior half of disc, each seta as long as distance between rows, spacing slightly closer within a row.

Distribution: Brazil: Ibicare, 27°09', 51°18' [Santa Catarina], 600 m, IX-1960, F. Plaumann.

Notes: The above treatment was based on the male holotype of *dissimilis* Schedl from Brazil.

Scolytodes praeceps Wood

Scolytodes praeceps Wood, 1977:521. Holotype ♀; Piedras Blancas 10 km E Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:397)

Scolytodes tardus Wood, 1981:127. Holotype ♀; Piedras Blancas 10 km E Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:399). *New synonymy*

Diagnosis: Epistomal margin armed by a small, median, pointed tubercle; female scape ornamented by

a conspicuous tuft of long, yellow hair; female frons broadly, somewhat irregularly flattened from epistoma to upper level of eyes, dorsal margin with a dense brush of long, yellow hair, continuing as lateral margins on diminishing basis almost to epistoma.

Male: Similar to female except frons convex on upper half, more shallowly, less extensively impressed on lower half, setae sparse, short, inconspicuous, epistomal tubercle present.

Female: Length 2.4–2.9 mm, 2.3 times as long as wide; color dark reddish brown. Frons broadly flattened from epistoma to upper level of eyes, median area below slightly inflated, epistomal margin with a small, pointed median tubercle; vestiture on upper margin to vertex dense, long, continued on lateral margins almost to epistoma but shorter, less abundant; female scape ornamented by a conspicuous tuft of long, yellow hair. Pronotum 1.0 times as long as wide; surface reticulate, rather coarsely, closely punctured to anterior margin, anterior third declivity, with no indication of asperities; almost glabrous, a few setae on anterior and lateral margins. Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; striae not impressed except 1 on posterior half of disc and on declivity, punctures moderately coarse, deep, in rows to base; interstriae almost smooth, about three times as wide as striae, punctures only slightly smaller than those of striae, confused on basal half of disc on 2 and 3. Declivity broadly convex, steep; striae 1 on upper half weakly impressed; punctures on all interstriae uniseriate. Vestiture of erect interstitial setae to base longer and finer on basal half of disc (each slightly longer than distance between rows, on declivity slightly stouter, slightly shorter than distance between rows).

Distribution: Colombia: Piedras Blancas 10 km E Medellin, Antioquia, 15-VII-1970, 2500 m, Nos. 660, 684, *Clusia*, SLW.

Biology: Boring in phloem of broken branches.

Notes: The above treatment was based on the type series of 13 specimens of *praeceps* Wood and on the holotype and 1 paratype of the smaller, abraded *tarda* Wood.

Scolytodes crinalis Wood

Scolytodes crinalis Wood, 1978:402. Holotype ♀; La Carbonera Experimental Forest 50 km airline NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:391)

Diagnosis: Epistoma with a conspicuous, rounded, median tubercle; scape without a tuft of long hair; pronotum punctured to anterior margin (no indication of asperities); striae and interstitial setae conspicuously present to base, erect interstitial setae restricted to declivity, not regular. Probably allied to *clusiae* complex of species.

Male: Similar to female except median area on lower half more distinctly convex (externally sexed with confidence only by means of abdominal terga 7 and 8).

Female: Length 2.2–2.5 mm, 2.3 times as long as wide; color very dark reddish brown. Frons transversely, rather

shallowly impressed on lower half, deepest at level of antennal insertion (without a weak, median, inflated crest as in male); surface reticulate, rather finely, obscurely punctured, vestiture sparse, short, inconspicuous (as in male). Pronotum 1.0 times as long as wide; dorsal profile almost uniformly convex from base, uniformly punctured, with no indication of asperities; vestiture of moderately abundant, fine, rather long hair about uniformly distributed. Elytra 1.5 times as long as wide, 1.9 times as long as pronotum; striae not impressed, punctures small, rather deep; interstriae about four times as wide as striae, punctures slightly smaller than those of striae, confused on all interstriae from base to apex. Declivity rather narrowly convex, steep; striae 1 and 2 obscure, others confused with those of interstriae; all punctures slightly smaller than on disc. Vestiture rather abundant from base to apex on striae and interstriae; striae setae about two-thirds as long as distance between striae rows, of fine, semirecumbent hair, interstitial setae on disc about equal to those of striae, on declivity some up to twice as long and occasionally suberect.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 14 X-1969, 2500 m, Nos. 50-C, 177, *Clusia*, SLW.

Biology: Boring in phloem of broken branches.

Notes: The above treatment was based on the type series of 11 specimens.

Scolytodes nitida (Eggers)

Scolytodes nitidus (Eggers), 1928:88 (*Prionosceles*). Holotype ♀; E Bolivia; NHMW, Wien (References in Wood & Bright c1992:396)

Diagnosis: Distinguished from *phoebeae* Wood by the female pubescence ending at upper level of eyes, margin of pubescence somewhat remote from margin of eye; and by the striae and interstitial punctures being organized into identifiable rows.

Female: Length 1.9 mm, 2.1 times as long as wide; color black. Frons flattened on median two-thirds from epistoma to upper level of eyes; central area mostly glabrous (punctured, not densely), lateral areas and above ornamented by long, yellow hair; pubescent area separated from margin of eye by distance equal to about width of an eye. Pronotum 1.0 times as long as wide; summit indefinite, at middle; surface obscurely reticulate, punctures moderately coarse, close, slightly smaller anteriorly and extending to anterior margin; glabrous. Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures rather small, deep, in definite rows; interstriae about three times as wide as striae, smooth, brightly shining, punctures three-fourths as large as those of striae, in definite rows. Declivity broadly convex, steep; sculpture similar to disc except all punctures slightly smaller. Glabrous.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the female holotype from Bolivia.

Scolytodes boliviae (Schedl)

Scolytodes boliviae (Schedl), 1951:80 (*Hexacolus*). Holotype ♀; Cochabamba, Bolivia; NHMW, Wien (References in Wood & Bright c1992:389)

Diagnosis: This species, known only from the female, is not in the key. It fits somewhere between *plumeriae* Wood (Plate LVII figs) and *serena* Wood. Its exact position cannot be determined without more and better material. Distinguishing features include (1) the eyes are rather narrowly separated above; (2) the small size, slender body form, minute strial and interstitial punctures (all uniseriate) are useful in phylogenetic placement.

Female: Length 1.2 mm, 2.7 times as long as wide; color yellowish brown (callow?). Frons convex on upper half of area below upper level of eyes, flattened on median half of lower area (less than lower half), surface smooth, shining above and below, a few rather coarse punctures above, more finely, closely punctured and with fine, sparse, rather short pubescence below. Pronotum 1.0 times as long as wide; anterior third declivous, finely asperate; dorsal profile of posterior two-thirds straight (horizontal), reticulate, finely, moderately punctured; glabrous, except for four setae at anterolateral corners. Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures minute, shallow, in rows; interstriae about three times as wide as striae, punctures minute, uniseriate, each less than half as large as a strial puncture. Declivity rather narrowly convex; surface about as on disc. Glabrous.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the female holotype from Bolivia.

Scolytodes grandis (Schedl)

Scolytodes grandis (Schedl), 1962:100 (*Hexacolus*). Holotype ♂; Cochabamba, Bolivia; NHMW, Wien (References in Wood & Bright c1992:393)

Diagnosis: This species is not in the above key. The holotype is a male; until the female is found, accurate placement in classification is not possible. It is allied to *frontoglabrata* (Schedl) in form, color, and shape, but it is much larger.

Male: Length 2.8 mm, 2.3 times as long as wide; color dark brown. Frons broadly convex from level of antennal insertions to vertex; surface reticulate, punctures minute, sparse, subglabrous; median third of epistomal area smooth, shining, extending half distance to level of antennal insertions, a pair of small pits at level of antennal insertion contain a pair of long setae. Pronotum 1.0 times as long as wide; surface finely reticulate, punctures very small, not deep, extending to anterior margin, some of those on anterior slope with a very slight wrinkle at puncture; glabrous, except for four setae at angles. Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures small, shallow; interstriae about four times as wide as striae, punctures

minute, about one third as large as strial punctures, punctures uniseriate on 1 and 3 from base to near declivity, confused on 2 and 4. Declivity broadly convex, steep; sculpture similar to disc except strial punctures reduced almost to size of those on interstriae; glabrous.

Distribution: Bolivia: Cochabamba [label written on green paper in ink by Schedl].

Notes: The above treatment was based on the male holotype from Bolivia.

Scolytodes frontoglabrata (Schedl)

Scolytodes frontoglabratus (Schedl), 1935:274 (*Hexacolus*). Holotype ♀; San Ignacio, Argentina; NHMW, Wien (References in Wood & Bright c1992:392)

Diagnosis: Distinguished from *puer* (Schedl) by the presence of a large, smooth, impunctate shining area on less than median half of the lower half of the female frons; and by the uniseriate punctures on discal interstriae 3 and 5.

Female: Length 2.1 mm, 2.2 times as long as wide; color dark reddish brown. Frons broadly flattened to distinctly above upper level of eyes, finely, densely punctured, except slightly less than median half on lower half smooth, shining, impunctate; punctured area with fine, abundant, rather long hair, longest setae on upper margin capable of extending less than half distance to epistoma. Pronotum 1.0 times as long as wide; rather strongly declivous on less than anterior half; strongly reticulate, punctures rather small, close, continued to anterior margin; low asperities transversely elongate; glabrous. Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures rather small, in rows; interstriae about three times as wide as striae, punctures about half as large as those of striae, those on 1, 3, and 5 in uniseriate rows to declivity, those on 2 and 4 strongly confused. Declivity broadly convex, steep; striae 1–3 distinct, interstriae 1–3 with punctures uniseriate at least on lower half. Glabrous, except for a few minute interstitial setae on sides of declivity.

Distribution: Argentina: San Ignacio, 1979, No. 342, Louis Dade.

Notes: The above treatment was based on the female holotype from Argentina.

Scolytodes puer (Schedl)

Scolytodes puer (Schedl), 1952:359 (*Hexacolus*). Holotype ♀; Paraguay; NHMW, Wien (References in Wood & Bright c1992:398)

Diagnosis: Distinguished from *phoebeae* Wood by the smaller size; by the strial punctures 1–4 being in distinguishable rows on the basal half of the disc; and by the female frons (described below).

Female: Length 1.8 mm, 2.2 times as long as wide; color dark reddish brown, basal third of pronotum and posterior half of elytra lighter brown. Frons on type largely concealed by pronotum, apparently broadly flattened from epistoma to upper level of eyes, a smooth

shining area on median fourth from epistoma to level of antennal insertions, uniformly punctured and pubescent over remaining area, punctures fine, rather dense, setae very fine, of moderate length. Pronotum 0.91 times as long as wide; dorsal profile strongly arched from base to anterior margin; anterior half with transversely long, subcarinate wrinkles, small punctures among wrinkles extend to anterior margin; posterior areas reticulate, punctures slightly larger, rather close; glabrous. Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures in discernible rows at least on basal third of disc, confused with those of interstriae before declivity; interstriae, on basal half of disc, about four times as wide as striae, punctures mostly smaller than those of striae, confused on 1–9 from base to apex. Declivity broadly convex, steep; striae 1 and 2 with discernible rows of punctures on upper half, confused elsewhere. Glabrous.

Distribution: Paraguay: "Paraguay."

Notes: The above treatment was based on the female holotype from Paraguay.

Scolytodes nitella (Schedl)

Scolytodes nitellus (Schedl), 1954:22 (*Hexacolus*). Lectotype ♀; 500 m, Rondon, Parana, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:395)

Diagnosis: Distinguished from *schwarzi* (Hopkins) from Florida by the smaller, shining, impunctate area on the female frons; by the smaller asperities on the anterior half of the pronotum; and by the more strongly reticulate pronotal disc and the much finer discal punctures.

Male: Similar to female except frons convex, frontal vestiture minute, sparse, inconspicuous.

Female: Length 1.4 mm, 2.2 times as long as wide; color dark reddish brown. Frons flattened on median three-fourths from epistomal area to slightly above upper level of eyes; apparently closely, finely punctured on most of flattened area except almost impunctate on median area on lower third (seen on type only at a strong angle, not clearly visible); vestiture of long, yellow hair, gradually becoming shorter toward central area. Pronotum 1.0 times as long as wide; asperities on anterior third distinctly smaller than in *schwarzi*; summit indefinite, anterior to middle of pronotum length; posterior areas strongly reticulate, punctures rather fine, moderately abundant; glabrous. Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures rather small (smaller than in *schwarzi*), in definite rows on posterior two-thirds of disc, slightly confused on 1 and 2 near base; interstriae about twice as wide as striae, smooth, shining, punctures uniseriate, each two-thirds as large as those of striae. Declivity rather broadly convex, steep; punctures distinctly smaller than on disc. Glabrous.

Distribution: Brazil: Rondon, Parana, 24°38' B, 54°07' L, 500 m, F. Plaumann.

Notes: The above treatment was based on the male and female syntypes that were incorrectly cited by Schedl (1979:168) as the holotype and allotype. I here designate as the lectotype of *Hexacolus nitellus* Schedl the female cited by Schedl (1979:168) as an allotype; this reversal is because the diagnostic characters in this genus are best seen in the female. The Schedl male, subsequently cited as the "holotype" by him, is here designated as the lectoallotype of this species. Both specimens are from the type locality cited above.

Scolytodes bruchi (Hagedorn), n. comb.

Scolytodes bruchi (Hagedorn), 1909:743 (*Hexacolus*). Lectotype ♀; Argentina; SMTD, Dresden, present designation (References in Wood & Bright c1992:389)

Diagnosis: Distinguished from *chapuisi* Wood by the absence of discernible discal striae, the area of interstriae 2 with numerous, very small, confused punctures, almost uniseriate on 3; a very slender species.

Female: Length 2.2 mm (2.5–3.0 mm in Hagedorn 1909:743), 2.6 times as long as wide; color light brown, glabrous. Frons rather broadly flattened on lower two-thirds, upper area on type concealed by pronotum; median half of visible area smooth, shining, glabrous, lateral areas very closely, rather finely punctured to epistoma. Pronotum 1.1 times as long as wide; surface uniformly, strongly reticulate, punctures very small, rather numerous, slope on anterior third entirely without wrinkles, asperities, or other irregularities; glabrous except at anterior and lateral margins. Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; striae and striae punctures not indicated; discal punctures very small, numerous, strongly confused in areas of interstriae 2 and 4, less numerous and almost uniseriate in areas of 3 and 5. Declivity restricted to less than posterior half, rather steep, convex; striae 1–3 on lower two-thirds indicated by rows of small punctures, interstitial punctures very small, uniseriate.

Distribution: Argentina: [La Plata], Prov. Buen Air; C. Bruch leg., Coll. Hagedorn 1915 (Hagedorn 1909:743).

Notes: This species was named from a series of unknown length and deposited in the Hamburg Museum, which was destroyed by WWII in 1944. One female cotype was found in the Dresden Museum. That female is here designated as the lectotype of *Hexacolus bruchi* Hagedorn, as indicated above. The species is also transferred to the genus *Scolytodes*.

Scolytodes declivistriata Schedl

Scolytodes declivistriatus Schedl, 1967:126. Holotype ♂?; Buenaventura, Colombia, intercepted at Tokyo, Japan; Tokyo Plant Protection Station (References in Wood & Bright c1992:391), see below

Diagnosis: Distinguished from *faceta* Wood by the broad female frons, with uniformly distributed setae from epistoma to vertex; by the reticulate pronotum,

with no asperities; by the smooth elytra with stria and interstitial punctures minute; and by the unique declivity as described below.

Male: Similar to female except frons more strongly convex, subglabrous.

Female: Length 2.3–2.4 mm, 2.3 times as long as wide; color very dark brown, almost black. Frons broadly flattened from epistoma to margin of eye (concealed on female paratype at hand by pronotum above); premandibular epistomal lobe large, broad, occupying median half; surface smooth, shining, finely, rather closely punctured and uniformly ornamented by rather long hair from lobe to upper level of eyes (without a smooth impunctate area on visible area); antennae missing except simple scape. Pronotum 1.0 times as long as wide; surface reticulate, punctures very minute, on anterior fifth punctures associated with a weak transverse line; glabrous. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; surface smooth, shining, striae not impressed (weakly near declivity), punctures minute (slightly larger near declivity), in definite rows; interstriae about eight to ten times as wide as striae, punctures confused, minute, equal in size to those of striae. Declivity rather narrowly convex, moderately steep; striae moderately impressed, punctures twice as large as those on disc; interstriae moderately convex, 2 and 4 narrowed and eliminated just below base of declivity, others end at junction with 9. Glabrous except for about one to three setae on lower declivity on mesal side of 3, 7, and 9.

Distribution: Colombia: Log 121 shipped from Buenaventura, intercepted at Tokyo, Japan, 22-III-1960, *Virola* sp., A. Koasa.

Biology: Specimens were removed from the bole of the host.

Notes: The above treatment was based on 1 female and 3 male paratypes in the Schedl Collection (NHMW, Wien). A male was described by Schedl and designated as the holotype and then returned to the Tokyo Plant Protection Station. However, records of the Tokyo Plant Protection Station indicate that this holotype was never returned to them by Schedl. The first specimen in the Schedl series, a male in reasonably good condition, is probably the missing holotype (see Wood in Wood & Bright c1992:3). The second specimen is the female that was described above. Specimens three and four are damaged males.

Scolytodes chapuisi Wood

Plate L

Scolytodes chapuisi Wood, 1977:210. Syntypes 2 ♂♂; Colombia; IRSNB, Brussels, automatic (Synonymy and references in Wood & Bright c1992:390)

Ctenophorus laevigatus Chapuis, 1869:49. Syntypes 2 ♂♂; IRSNB, Brussels, preoccupied by Ferrari 1867:77

Hexacolus levis Blackman, 1943:382. Holotype ♀; Paraiso, Canal Zone, Panama; USNM, Washington, preoccupied by *laevis* Eggers 1928 [Code, Article 58(2)]

Diagnosis: Distinguished from *serena* Wood by the smaller size, by the total absence of preasperate irregu-

larities on the anterior slope of the pronotum; and by the much smaller, less deeply impressed elytral punctures.

Male: Similar to female except frons convex, subglabrous.

Female: Length 1.8–2.2 mm, 2.4 times as long as wide; color dark reddish brown. Frons weakly convex, lower two-thirds of median half smooth, shining, glabrous; lateral areas from level of antennal insertions to vertex finely, closely punctured, punctured area bearing a brush of long, yellow hair; dorsal margin of pubescent area narrowly arched above (less than 90 degrees). Pronotum 1.0 times as long as wide; surface reticulate, minutely, rather closely punctured from base to anterior margin, anterior slope with no indication of preasperate wrinkles; about four setae at lateral and anterior margins. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures minute, weakly impressed; interstriae at least four times as wide as striae, punctures minute, half as large as those of striae, uniseriate. Declivity rather narrowly convex, steep; punctures more distinctly impressed than on disc, confused. Glabrous.

Distribution: Panama to Colombia and Venezuela.

Colombia: “Colombie.”

Venezuela: Colonia Tovar, Aragua, 4-V-1970, 1700 m, Nos. 50-C, 509, *Cecropia* leaf petioles, SLW; El Laurel Experimental Farm 12 km SW Caracas, 1-V-1970, 1300 m, No. 475, *Cecropia* leaf petioles, SLW; Rancho Grande, Aragua, 9-IV-1979, 1700 m, No. 425, *Cecropia* leaf petioles, SLW.

Biology: Boring in fallen leaf petioles just beneath outer epidermis.

Notes: The above treatment was based on the 2 male syntypes of *Ctenophorus laevigatus* Chapuis from Colombia, and on 94 specimens from Venezuela. It is possible the Chapuis syntypes were taken before Venezuela and Panama were separated from Colombia; if so, the “Colombie” record could have come from Venezuela or Panama.

Scolytodes nitens (Schedl)

Scolytodes nitens (Schedl), 1954:23 (*Hexacolus*). Lectotype ♂; 500 m, Rondon, Parana, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:396)

Diagnosis: This species is not in the above key. The 2 Schedl syntypes examined are both males; it is presumed they fit somewhere near *serena* Wood; however, without a female, their exact placement in classification cannot be ascertained. The carina of interstriae 10 extends well behind the level of the hind coxae; there is no small denticle on the posterior face near the apex of the protibia, and (on 1 syntype) erect interstitial setae occur only on odd-numbered interstriae.

Male: Length 1.4 mm, 2.4 times as long as wide; color dark reddish brown. Frons rather strongly convex from epistoma to vertex, strongly reticulate; sparse punctures very minute; glabrous above, sparse hair on lower fourth.

Pronotum 1.0 times as long as wide; summit near middle; posterior half (and between asperities anteriorly) strongly reticulate, punctures very minute, moderately close. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; striae not impressed; interstriae three times as wide as striae, surface smooth, shining, punctures minute (about one-third as large as those of striae), uniseriate. Declivity rather broadly convex, steep; sculpture about as on disc. Vestiture of very sparse rows of moderately long, erect setae on odd-numbered interstriae on and near declivity (not more than four setae in a row).

Distribution: Brazil: Nova Teutonia, Santa Catarina, 19-XI-1949, F. Plaumann.

Notes: This species was based on a syntypic series. Schedl (1979:168) later invalidly labeled and cited 1 of these syntypes as the holotype. In order to clarify the status of this species, I here designate that male 'holotype' as the lectotype of *Hexacolus nitens* Schedl. Although both syntypes were labeled by Schedl as females, both are actually males.

Scolytodes serena Wood

Scolytodes serenus Wood, 1977:521. Holotype ♀; La Mucuy 20 km W Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:399)

Diagnosis: Distinguished from *chapuisi* Wood by the larger size; by the presence of preasperate wrinkles on the anterior slope of the pronotum; and by larger, deeper elytral punctures.

Male: Similar to female except frons convex, almost glabrous.

Female: Length 2.7–3.1 mm, 2.4 times as long as wide; color moderately dark yellowish brown. Frons resembling *chapuisi* except dorsal margin of pubescent area more broadly arched (but less than 90 degrees), setae on lateral margins end distinctly above level of antennal insertions. Pronotum 1.0 times as long as wide; surface reticulate, punctures small, moderately close; anterior one-fourth with feeble preasperate wrinkles associated with punctures (none acute); glabrous except for 4 strong setae (2 at anterior margin, 2 at lateral base). Elytra 1.7 times as long as wide, 1.9 times as long as pronotum; striae not impressed, punctures rather small, deep; interstriae slightly more than twice as wide as striae, smooth, shining, punctures two-thirds as large as those of striae, uniseriate, except moderately confused on 3 and weakly on 2 on basal half of disc. Declivity rather narrowly convex, steep; striae 1 feebly impressed; all punctures slightly deeper than on disc. Elytra glabrous.

Distribution: Venezuela: La Mucuy, 20 km W Merida, Merida, 10-X-1969, 2500 m, No. 46, *Meriana*, SLW.

Biology: Boring in phloem of broken branches.

Notes: The above treatment was based on the type series of 40 specimens.

Scolytodes gunnerae Wood, n. sp.

Scolytodes gunnerae Wood: Holotype ♀; 6 km ENE Vara Blanca, Heredia, Costa Rica; USNM, Washington, designated below

Diagnosis: Distinguished from *serena* Wood by the larger size; by the more nearly flat median shining area on the lower frons, the vestiture on the dorsal and lateral areas much less abundant; pronotum with subasperate irregularities on the anterior third smaller and less numerous; and by the smaller elytral punctures.

Male: Similar to female except frons more narrowly, less strongly impressed to upper level of eyes, setae absent, punctures very sparse.

Female: Length 3.0–3.6 mm, 2.5 times as long as wide; color yellowish brown. Frons flattened on median three-fourths to above upper level of eyes, a feeble median impression at upper level of eyes; upper half finely, closely punctured, punctured area continuing ventrad to epistoma, median third smooth, shining, impunctate and feebly convex. Pronotum 1.02 times as long as wide; punctures on anterior third with their anterior margin shining, feebly elevated (much less than in *serena*); posterior areas reticulate, punctures minute, rather numerous; sparse setae at lateral margins and a few near anterior margin. Elytra 1.6 times as long as wide, 1.9 times as long as pronotum; surface smooth, shining, striae punctures small, distinctly impressed in rows, interstitial punctures slightly smaller than those of striae, numerous, strongly confused. Declivity moderately steep, convex, similar to disc except punctures on striae 1 minute, discernible to near apex, 2 confused with interstitial punctures.

Distribution: Costa Rica (Heredia).

Type material: The female holotype, male allotype, and 27 paratypes were taken 6 km ENE Vara Blanca, Heredia, Costa Rica, 10°11'N, 84°7'W, 27-III-2002, *Gunnera insignis* leaf petioles and veins, K. Nishida. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Scolytodes bicolor (Eggers)

Scolytodes bicolor (Eggers), 1931:33 (*Hexacolus*). Holotype ♂; Sao Paulo, Brazil; NMPC, Prague (References in Wood & Bright c1992:389)

Diagnosis: Distinguished from *perdita* Wood by the smaller size; by the more slender body and pronotum; by the punctures on discal interstriae 2 being uniseriate to the base; and by the very different female frons, with sparse, short setae as described below.

Female: Length 1.6–1.7 mm, 2.5 times as long as wide; color of pronotum disc and elytra light brown, pronotum anterior third and sides and basal third of elytral disc from suture to striae 2 or 3 very dark brown. Frons flattened, smooth, glabrous on median third from near epistoma to upper level of eyes, lateral and upper margins of glabrous area with a row of long setae from epistomal margin to upper margin, two to four setae at

median line above short (one-fourth as long as adjacent setae); antennal club small, subacutely pointed at apex, sutures 1 and 2 obscure. Pronotum 1.0 times as long as wide; sides on basal half almost straight and parallel, rather broadly rounded on subcostate anterior margin; summit indefinite, near middle of pronotum length; anterior slope rather steep, asperities rather large, close, broad, spaces between asperities reticulate, with no punctures except near summit; posterior areas reticulate, punctures distinctly impressed, rather close, almost as large as those of striae; glabrous. Elytra 1.35 times as long as wide, 1.35 times as long as pronotum; disc occupying basal 70 percent of elytra length; striae not impressed, punctures moderately large, deep, in definite rows; interstriae smooth, shining, punctures about two-thirds as large as those of striae, in definite rows. Declivity steep, strongly convex, profile of suture moderately convex; striae 1 feebly impressed, 2 and 3 not impressed, punctures on upper half about as on disc, decreasing in size on lower half; interstriae with punctures half as large as those of interstriae, slightly confused. Glabrous.

Distribution: Brazil: Sao Paulo.

Notes: The above treatment is based on 2 female cotypes in the USNM, Washington.

Scolytodes perditata Wood

Scolytodes perditus Wood, 1967:123. Holotype ♀; Fort Clayton, Canal Zone, Panama; USNM, Washington (References in Wood & Bright c1992:397)

Diagnosis: Female distinguished from female *ovalis* (Eggers), from Guadeloupe Island and Panama, by radically more extensively flattened and much more abundantly pubescent frons. Male distinguished from both male and female *ovalis* with extreme difficulty; male *perditata* with anterolateral asperities on pronotum smaller, transverse ridges shorter, more confused, confined to less than anterior half near lateral margin, in *ovalis* asperate ridges higher, much longer, occupying anterior half to two-thirds of area near lateral margin; male *ovalis* with anterior margin of most discal punctures on posterior half of pronotum with a smooth, shining spot, in *perditata* this spot not present (occasionally present on anterior half).

Male: Similar to female except frons convex, smooth, shining, punctured, almost glabrous.

Female: Length 1.8–2.1 mm, 2.1 times as long as wide; color yellowish brown. Frons broadly, rather strongly flattened from epistoma to well above upper level of eyes, central area from epistoma to at least half distance to upper level of eyes glabrous; dorsal and lateral margins almost to level of antennal insertions with a dense brush of long, yellow hair, tips of longest setae on vertex almost attain level of antennal insertion. Pronotum 1.0 times as long as wide; reticulate, dorsal profile less strongly arched than in *ovalis*, asperities on anterior third smaller, transversely shorter, more strongly confused, punctures extend to anterior margin; punctures

on posterior half of disc rather small, anterior margin on each puncture reticulate, without a smooth, shining spot; glabrous except a few hairs on anterior margin. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures rather small, distinctly impressed, in rows; interstriae about four times as wide as striae, smooth, shining, punctures half as large as those of striae, moderately confused on 1 to 5 on at least basal half of disc. Declivity broadly convex, steep; punctures uniseriate. Glabrous, except interstriae 5, 7, and 9 each with one to five short, erect, interstitial setae.

Distribution: Panama: Fort Clayton, Canal Zone, 22-XII-1963, 50 m, No. 321, *Cecropia* twigs, SLW.

Biology: Boring in phloem of twig terminals of a broken branch. Both *perditus* and *ovalis* were mixed together in this sample (No. 321) before it was realized that 2 species were represented.

Notes: The above treatment was based on the female holotype, male allotype, and 3 male paratypes of *Scolytodes perditata* Wood. Although not recorded from South America, *perditata* is included here because its identification will present a problem if, and when, it is found there.

Scolytodes eggersi (Schedl)

Scolytodes bicolor Eggers, 1943:363. Holotype ♀; Cochabamba, Bolivia; MNHN, Paris, lost, preoccupied by Eggers 1931:33 (References in Wood & Bright c1992:391)

Hexacolus eggersi Schedl, 1952:346. Holotype ♀; Cochabamba, Bolivia; MNHN, Paris, lost, automatic

When a loan of the female holotype of *Scolytodes bicolor* Eggers (1943:363) was received by me; this holotype was dangling from its cardboard paper point by a single metatarsus. As I was looking at it through the microscope it fell from the mount. I immediately remounted the specimen, using jellied shellac glue. Thirty minutes later I made superficial comparisons of this holotype to related species in my collection and then placed it on a pinning block near the microscope while I replaced the 3 unit trays of my specimens in the drawer where they belonged. I was always more than 30 cm from the type. When I then reached for the type it was gone from its pin. The curator of the MLBM Museum collection of insects and I began an hours-long search for the type but could not find it. Something must have touched the pin thereby causing it to flip the specimen to an unknown location. My brief notes taken from the type before it was lost follow:

Scolytodes bicolor Eggers = *Hexacolus eggersi* Schedl, female holotype, estimated as 2.5 mm, body color dark reddish brown, label "Museum Paris; Bolivia, Cochabamba (Germain), H. Donickier, 1907." Most of frons concealed by prothorax, 2 bundles of 5–6 setae were projecting from the upper frons orad as is typical of some *Scolytodes* (similar to type of female *S. medius* Eggers = *S. maurus* Blandford). The body was estimated to be 2.6–2.7 times as long as wide; the pronotum was reticulate, the anterior slope of the pronotum was

asperate, with no punctures between the asperities. The elytra had very few short setae, punctures on the elytral disc were small and inconspicuous. It superficially resembled *S. alni* Wood but was definitely not that species.

Scolytodes pseudoacuminata (Schedl)

Scolytodes pseudoacuminatus (Schedl), 1935:51 (*Hexacolus*). Syntypes, ♂ ♀; Saude bei Sao Paulo, Brazil; DEI, Munchenberg; NHMW, Wien (References in Wood & Bright c1992:398)

Diagnosis: Distinguished from *lepida* Wood by the larger size; by the more numerous, confused pronotal asperities; and by the very different female frons as described below.

Male: Similar to female except frons convex from epistoma to vertex, surface reticulate, punctures obscure, vestiture short, sparse.

Female: Length 2.5–2.7 mm, 2.2 times as long as wide; color dark reddish brown. Frons broadly flattened from epistoma to well above upper level of eyes; slightly more than median half on lower 60 percent (of area below upper level of eyes) forming a smooth, shining, impunctate, subquadrate, slightly elevated callus; area above callus densely, finely punctured on median three fourths from callus to vertex; margin of punctured area ornamented by long, reddish yellow hair across dorsal margin and down sides to epistoma. Pronotum 1.0 times as long as wide; anterior third armed by numerous, small, confused asperities; summit indefinite; posterior areas reticulate, punctures rather coarse, close, moderately deep; glabrous except for four setae on anterior and posterior angles. Elytra 1.2 times as long as wide, 1.2 times as long as pronotum; striae not impressed, punctures moderately large, shallow, in uniseriate rows; interstriae three to four times as wide as striae, smooth, subshining, punctures half to two-thirds as large as those of striae, shallow, confused on 1 to 9. Declivity broadly convex, steep; striae 1 weakly impressed; interstriae 2 narrower than on disc, its punctures uniseriate, punctures confused on 1 and lateral areas (3 to 9). Glabrous.

Distribution: Brazil: Saude bei Sao Paulo, 27-IX-1921, J. Melzer.

Notes: The above treatment was based on 2 male and 2 female syntypes from Brazil in the NHMW, Wien. This species was based on a syntypic series of unknown extent in which the sexes were reversed in the original description. Schedl later corrected the sex labels in his collection.

Scolytodes fulminea Wood

Scolytodes fulmineus Wood, 1977:217. Holotype ♀; La Carbonera Experimental Forest 50 km airline NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:392)

Diagnosis: This is a member of the *clusiae* Wood complex of species in which the pronotum varies from unarmed to finely, sparsely asperate, interstitial punctures

are sparse and widely separated to obsolete, interstitial setae are sparse and only on odd-numbered interstriae, interstriae may have the carina of 10 end at the level of the hind coxae or continue (with or without a carina), and female frontal vestiture does not extend above the upper level of the eyes and is of about uniform length. One may distinguish *fulminea* from allied species by the female frons having the median third from epistoma to upper level of eyes smooth, shining, impunctate, lateral thirds densely, minutely punctate and bearing uniformly distributed, fine hair of rather short, uniform length.

Male: Similar to female except frons rather strongly convex, surface smooth, shining below, weakly reticulate above, punctures sparse, small.

Female: Length 1.6–1.9 mm, 2.6 times as long as wide; mature color black. Frons broadly flattened from epistoma to upper level of eyes, median third (above) to almost half (below) smooth, shining, impunctate from epistoma almost to upper level of eyes; lateral thirds finely, densely punctured, punctured area with moderately abundant fine, rather short hair of uniform length, not longer at margins. Pronotum 1.1 times as long as wide; surface strongly reticulate, rather coarsely, sparsely punctured on basal two-thirds, anterior one-fourth more strongly declivous, punctures reduced in size, attain anterior margin in lateral areas, median area with a few sparse, very fine asperities; glabrous except a few short setae near anterior margin. Elytra 1.6 times as long as wide, 1.8 times as long as pronotum; striae 1 feebly, others not impressed, punctures rather coarse, close, deep; interstriae slightly more than twice as wide as striae, smooth, shining, punctures often obsolete on even-numbered interstriae, sparse, minute on odd-numbered rows, uniseriate when present. Declivity rather narrowly convex, steep; similar to disc except interstriae narrower, 2 very narrow. Vestiture of very sparse, erect hair present on odd-numbered interstriae, a seta occasionally attaining base.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 14 X-1969, 2500 m, Nos. 50-B, 50-C, *Clusia*, SLW.

Biology: Boring in phloem of broken branches.

Notes: The above treatment was based on the type series of 13 specimens and on 33 other specimens.

Scolytodes anceps Wood

Scolytodes anceps Wood, 1981:126. Holotype ♀; Piedras Blancas 11 km W Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:388)

Diagnosis: Distinguished from *irazuensis* Wood (Costa Rica) by the less strongly impressed female frons, with the lateral calluses less conspicuous and the dorsal setae more abundant; and by the much larger elytral punctures.

Male: Similar to female except frons convex, reticulate, sparsely punctured, subglabrous.

Female: Length 1.3–1.4 mm, 2.4 times as long as wide; mature color very dark brown. Frons with median half

shallowly impressed, lateral areas weakly elevated as calluses from level of antennal insertions at least half distance to upper level of eyes; median area dull, rather coarsely, closely, deeply punctured; dorsal margin and upper lateral margins ornamented by a dense row of moderately long hair. Pronotum 1.0 times as long as wide; surface reticulate, punctures moderately coarse, shallow, smaller and extending to anterior margin on anterior third; glabrous except for four setae, one at each anterior and posterior angle. Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; striae 1 weakly, others not impressed, punctures minute, in rows, some obscure; interstriae about three times as wide as striae, punctures minute to obsolete, uniseriate. Declivity narrowly convex, steep; sculpture about as on disc. Vestiture of sparse, erect, moderately long hair on odd-numbered interstriae; most specimens with at least some very minute strial and interstitial setae.

Distribution: Colombia: Piedras Blancas 11 km W Medellin, Antioquia, 17-VII-1970, 2300 m, No. 691, fallen *Cecropia* leaf petioles, SLW.

Biology: Boring in fallen petioles just below the outer epidermis.

Notes: The above treatment was based on the type series of 39 specimens.

Scolytodes semipunctata Wood

Scolytodes semipunctatus Wood, 1978:405. Holotype ♀; Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:399)

Diagnosis: A pubescent species that is distinguished from *habilis* Wood by the stouter body, with elytral punctures on anterior disc in uniseriate rows.

Male: Similar to female except upper frons with median crest weakly, distinctly elevated.

Female: Length 1.7–2.0 mm, 2.1 times as long as wide; color very dark brown. Frons convex from epistoma to vertex, surface reticulate, sparsely, rather coarsely punctured; vestiture very sparse, inconspicuous. Pronotum 1.0 times as long as wide; surface reticulate, punctures small, rather close, attaining anterior margin, with no indication of asperities; vestiture of abundant, fine, moderately long hair uniformly distributed. Elytra 1.5 times as long as wide, 2.0 times as long as pronotum; striae not impressed, punctures moderately coarse, deep, smaller toward base and declivity; interstriae slightly more than twice as wide as striae, surface smooth, shining, punctures about half as large as those of striae, confused near declivity. Declivity broadly convex, steep; striae discontinuing before middle of declivity, all punctures much smaller than on disc, confused. Vestiture of fine, moderately long hair, shorter and much more abundant on declivity.

Distribution: Venezuela: Merida (between stops 2 and 3 on Pico Bolivar Teleferico), Merida, 27-II-1970, 2500 m, No. 331, tree bole, SLW.

Biology: Boring in phloem of bole.

Notes: The above treatment was based on the type series of 12 specimens.

Scolytodes banosa (Hagedorn)

Scolytodes banosus (Hagedorn), 1909:743 (*Hexacolus*). Holotype ♀; Banos, Ecuador; MNHN, Paris (References in Wood & Bright c1992:389)

Diagnosis: Distinguished from *semipunctata* Wood by the larger size; by the mostly smooth, shining pronotum; by the much longer, more abundant elytral setae; and by the discal striae that were not impressed.

Female (?): Length 2.7 mm, 2.2 times as long as wide; color dark reddish brown. Frons weakly convex, smooth, shining on lower half, feebly subreticulate above, punctures rather coarse, deep, sparse; setae sparse, inconspicuous; antennal club small, suture 1 obscure. Pronotum 1.0 times as long as wide; sides and anterior margin moderately arcuate; surface smooth, shining on central half, weak reticulation on all margins; punctures rather small, distinct, rather widely spaced; vestiture of moderately abundant, rather long, fine setae. Elytra 1.6 times as long as wide, 1.8 times as long as pronotum; disc occupying 70 percent of elytra length; elytral surface smooth, shining, punctures small, close, distinct, mostly confused, those on striae 2–4 in obscure rows. Declivity rather steep, moderately convex, apical margin rather narrowly rounded from dorsal aspect; sculpture about as on disc except punctures slightly smaller, closer, more strongly confused. Vestiture of rather abundant, fine, long setae from base to apex, slightly longer and more abundant on declivity.

Distribution: Ecuador: Banos, R. Haensch S.

Notes: The above treatment was based on the female holotype of *Hexacolus banosus* Hagedorn.

Scolytodes aterrima Wood

Scolytodes aterrimus Wood, 1988:32 (*Hylocurosoma*). Holotype ♂; Cochabamba, Bolivia; MNHN, Paris, replacement name, automatic (Synonymy and references in Wood & Bright c1992:388)

Hylocurosoma ater Eggers, 1943:371. Holotype ♂; Cochabamba, Bolivia; MNHN, Paris, preoccupied by Eggers 1943:365

Diagnosis: Distinguished from *habilis* Wood by the smaller size; by the smooth, shining pronotum; by the recumbent strial setae and erect interstitial setae; and by the larger, less dense elytral punctures.

Male: Length 1.5 mm, 2.7 times as long as wide; color very dark reddish brown. Frons on lower half smooth, shining, convex, punctures rather small, not close (concealed on upper half of type by pronotum). Pronotum 1.1 times as long as wide; sides weakly arcuate, anterior margin rather broadly arcuate; surface mostly smooth, shining, punctures rather coarse, close; vestiture of rather fine, abundant, moderately long setae. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; disc occupying 67 percent of elytra length; disc smooth, shining between punctures, punctures rather large, confused.

Declivity rather steep, strongly convex; sculpture about as on disc, punctures slightly smaller. Vestiture of moderately long, mostly recumbent, fine setae, and erect longer interstitial setae, setae moderately abundant from base to apex of elytra.

Distribution: Bolivia: Cochabamba (Germain), 1907, Donckier.

Notes: The above treatment was based on the male (?) holotype of *Hylocurosoma ater* Eggers.

Scolytodes habilis Wood

Scolytodes habilis Wood, 1978:403. Holotype ♀; 30 km E Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:393)

Diagnosis: Distinguished from *semipunctata* Wood by the smaller size; by the more slender body form; by the strongly confused interstitial punctures to the base; and by the more abundant vestiture on the basal half of the elytra.

Male: Similar to female, distinguished with confidence only by abdominal terga 7 and 8.

Female: Length 1.5–1.7 mm, 2.4 times as long as wide; color black. Frons convex from epistoma to vertex; surface reticulate, punctures small, shallow, rather sparse; vestiture of fine, very sparse, inconspicuous hair. Pronotum 1.0 times as long as wide; surface reticulate; punctures on basal half coarse, close, deep, of reduced size on anterior half, almost obsolete by anterior margin; vestiture of fine, rather short, abundant, semirecumbent hair, a few much longer, erect setae near margins. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures in rows, small, rather deep; interstriae about four times as wide as striae, surface smooth, shining, punctures slightly smaller than those of striae, strongly confused to base. Declivity broadly convex, steep; striae 1 and 2 recognizable on basal two-thirds, punctures greatly reduced in size, obsolete below and laterally; interstitial punctures very small, confused. Vestiture of fine, abundant, rather short, semirecumbent hair, more abundant on declivity.

Distribution: Venezuela: 30 km E Merida, 8-I-1970, 2500 m, No. 220, *Croton*, SLW.

Biology: Boring in phloem of broken branches.

Notes: The above treatment was based on the type series of 17 specimens.

Scolytodes decora Wood

Scolytodes decorus Wood, 1978:402. Holotype ♂; 40 km E Canton, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:391)

Diagnosis: Distinguished from *punctata* (Eggers) by the much shorter setae on the declivital striae and interstriae; and by the declivital punctures being organized into recognizable rows.

Male: Similar to female; distinguished by abdominal terga 7 and 8.

Female: Length 1.4–1.6 mm, 2.3 times as long as wide; color almost black. Frons convex above level of antennal insertions, reticulate and finely, sparsely punctured above; area from epistoma to level of antennal insertions slightly elevated into a callus, a pair of small, impressed, subcircular punctured areas in lateral areas within this callus; vestiture very sparse, short, inconspicuous. Pronotum 1.0 times as long as wide; surface reticulate, punctures rather coarse, moderately close, attaining anterior margin; vestiture very fine, short, rather sparse, generally distributed (abraded on holotype). Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; surface smooth, shining, punctures of striae and interstriae coarse, deep, confused. Declivity convex, steep; similar to disc except punctures slightly smaller. Vestiture hairlike, almost erect, in distinguishable striae and interstitial rows, striae hairlike setae about half as long as distance between striae rows, interstitial setae about equal in length to distance between interstitial rows.

Distribution: Venezuela: 40 km E Canton, Barinas, 8-III-1970, 70 m, No. 332, *Nectandra*, SLW.

Biology: Boring in the phloem of broken branches.

Notes: The above treatment was based on the type series of 4 specimens.

Scolytodes punctata (Eggers)

Scolytodes punctatus (Eggers), 1943:368 (*Hylocurosoma*). Holotype, sex?; Cochabamba, Bolivia; MNHN, Paris (References in Wood & Bright c1992:398)

Diagnosis: Distinguished from *decora* Wood by the much longer striae and interstitial setae; those on the declivity are longer and most are curved; and by the confused punctures on the elytral declivity.

Female: Length 1.9 mm, 2.2 times as long as wide; color dark reddish brown. Frons as in *decora*. Pronotum 1.1 times as long as wide; similar to *decora* except punctures on basal half distinctly larger, those on anterior third smaller, setae finer, much longer, at least some semirecumbent. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures rather coarse, deep; interstriae twice as wide as striae, smooth, shining, punctures uniseriate, deep, at base two-thirds as large as those of striae, about equal to those of striae at base of declivity. Declivity broadly convex, steep; surface smooth, shining, punctures of striae and interstriae smaller than on declivity, confused. Vestiture of fine, long hair to base; striae setae on disc almost as long as distance between striae rows (slightly longer on declivity), interstitial setae on disc slightly longer than distance between rows, on declivity twice as long; most setae on declivity curved.

Distribution: Ecuador to Bolivia.

Bolivia: Cochabamba [collected by Woytkowski].

Ecuador: 8 km E Savilla de Oro, Azuay, 2400 m, 17-III-1955, E.I. Schlinger, E.S. Ross.

Notes: The above treatment was based on 1 specimen, presumably a female, from Ecuador, that was compared

by me in 1965 to a female cotype in the Schedl Collection at NHMW, Wien.

Scolytodes vescula Wood

Scolytodes vesculus Wood, 1981:128. Holotype ♂; Piedras Blancas 10 km E Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:400)

Diagnosis: Distinguished from *punctifer* Wood (near *cecropiavora* Wood) by the much more extensive, more numerous fine pronotal asperities; by the finer, confused punctures on the elytral disc; and by the uniseriate, erect interstitial setae on the posterior half of the elytra.

Male: Length 1.4–1.5 mm, 2.3 times as long as wide; color black. Frons convex from epistoma to vertex; surface reticulate, punctures sparse, rather coarse, shallow; vestiture fine, sparse, inconspicuous. Pronotum 1.0 times as long as wide; anterior half with rather numerous, small, sometimes indefinite asperities; surface reticulate, punctures small on posterior half; vestiture of fine, semirecumbent, moderately abundant hair. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae 1 obscurely indicated, others with punctures confused with those of interstriae, all punctures small, close. Declivity rather narrowly convex, steep; surface shining, all punctures very small, confused. Vestiture of fine, moderately long, semirecumbent hair, on and near declivity with uniseriate rows of moderately coarse, erect interstitial setae (on 1–8), each erect seta as long as distance between rows, spaced within a row somewhat more closely.

Distribution: Colombia: Piedras Blancas 10 km E Medellin, Antioquia, 15-VII-1970, 2500 m, No. 678, *Croton guianensis*, SLW.

Biology: Boring in the phloem of broken branches.

Notes: The above treatment was based on the male holotype and on 2 male paratypes from Colombia.

Scolytodes glabrella (Schedl)

Scolytodes glabrellus (Schedl), 1954:21 (*Hexacolus*). Syntypes ♂ ♀; Rondon, Parana, Brazil; NHMW, Wien (References in Wood & Bright c1992:393)

Diagnosis: Distinguished by the presence of 1 small denticle on the posterior face near the protibia apex, a carinate posterior half of interstriae 10, and asperities on the anterior third of the pronotum; by the female frontal setae not extending above the upper level of the eyes; and by the presence of a median, subcarinate callus on the lower two-thirds of the female frons.

Male: Similar to female except frons convex, lower third coarsely, very closely punctured, very sparsely, inconspicuously pubescent.

Female: Length 1.5–1.8 mm, 2.3 times as long as wide, color very dark reddish brown. Frons convexly flattened from epistoma to upper level of eyes, this area densely, finely punctured except a shining, subacute

median carina on lower half; vestiture on lateral and dorsal margins longer, more numerous, shorter in central area, epistomal area with a conspicuous brush of hair. Pronotum 1.04 times as long as wide; surface reticulate and rather finely, moderately punctured on slightly more than posterior half, more strongly declivous and finely, closely asperate in front; glabrous except for very few setae near anterior margin. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures small, rather deep, in rows; interstriae twice as wide as striae, smooth, shining, punctures about half as large as those of striae, uniseriate except confused on anterior half of 2. Declivity broadly convex, steep; punctures slightly smaller than on disc, in rows. Glabrous (abraded?) in most specimens, very minute striae and interstitial setae on declivity in a few specimens.

Distribution: Brazil: Rondon, Parana, 24°38'B, 54°07'W, X-1952, 500 m, F. Plaumann.

Notes: The above treatment was based on 1 male and 1 female paratype, and on 2 other males from the same locality (Rondon).

Scolytodes pusilla (Eggers)

Scolytodes pusillus (Eggers), 1943:367 (*Hylocurosoma*). Holotype ♂?; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:398).

Diagnosis: This species is not in the above key. The male is distinguished from the male of *naevius* Wood by the smaller size; by the very coarse, deep, close punctures on the pronotum disc; and by the much larger, deeper striae punctures, with the striae distinctly wider than the interstriae.

Male: Length 1.2 mm, 2.2 times as long as wide; color dark reddish brown. Frons broadly convex, surface reticulate above, punctures moderately coarse; vestiture sparse, hairlike, short. Pronotum 1.0 times as long as wide; summit indefinite, near middle, anterior slope moderately, closely asperate; posterior areas very coarsely, deeply punctured, punctures spaced by less than half diameter of a puncture, reticulation obscure, but present; vestiture of fine, rather short, recumbent hair. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures coarse, deep, close; interstriae slightly narrower than striae, smooth, shining, interstitial punctures minute, uniseriate. Declivity broadly convex, steep; as on disc except striae slightly narrower. Vestiture on declivity of a few erect, blunt setae on odd-numbered interstriae, sparse, short, ground cover present on some interstriae (partly abraded?).

Notes: The above treatment was based on the holotype from Bolivia, presumably a male.

Scolytodes sparsepilosa Wood, n. sp.

Scolytodes sparsepilosa Wood: Holotype ♀; 21 km W Tucuman, Tucuman, Argentina; USNM, Washington, designated below

Diagnosis: Distinguished from *glabrella* Schedl by the absence of a longitudinal median carina on the female frons; by the presence of a short, weak transverse carina on the female frons; and by the uniseriate, smaller to obsolete punctures on discal interstriae 2.

Male: Similar to female except frons rather strongly convex, reticulate, subglabrous.

Female: Length 1.9–2.0 mm, 2.7 times as long as wide; color yellowish brown, anterior half of pronotum darker (mature color?). Frons with a transverse callus (or weak carina) on median one fourth at one-third of length of frons below upper level of eyes; epistomal margin slightly elevated, smooth, shining, a slight dorsal extension at median line; area from epistomal callus to carina shallowly, subconcavely impressed, impressed area closely, rather finely punctured on median two thirds; lateral and dorsal areas reticulate; vestiture on impressed area hairlike, very fine, erect, moderately long. Pronotum 1.0 times as long as wide; surface reticulate, posterior half finely, moderately punctured, anterior half declivous and armed by low, transversely long, subasperate wrinkles, some punctures continue to anterior margin; glabrous except four setae near anterior margin. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures small, rather shallow; interstriae shining, almost smooth, punctures minute to obsolete, one fourth as large as those of striae, uniseriate. Declivity broadly convex, steep; sculpture about as on disc. Vestiture restricted to declivity, consisting of one to three short, hairlike setae on each of interstriae 7 and 9.

Distribution: Argentina (Tucuman).

Type material: The female holotype and male allotype were taken 21 km W Tucuman, Tucuman, Argentina, 18-VIII-1969, C.W. & L. O'Brien. The holotype and allotype are in the U.S. National Museum, Washington.

Scolytodes naevia Wood

Scolytodes naevius Wood, 1981:127. Holotype ♀; 40 km SE Socopo, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:395)

Diagnosis: Distinguished from *glabrella* (Schedl) by the more extensively punctured female frons, which bears on the median one-third on the upper half a pair of smooth, shining, weakly elevated calluses; by the elytral punctures bearing extremely minute striae and interstitial setae (each shorter than diameter of a puncture); and by the larger pronotal asperities.

Male: Similar to female except frons strongly convex, reticulate, subglabrous.

Female: Length 1.3–1.7 mm, 2.7 times as long as wide; color yellowish brown. Frons flattened on lower two-thirds of area below upper level of eyes and closely, finely punctured except for a pair of smooth, shining, longitudinal calluses on median third of upper third of punctured area; upper and lateral areas reticulate; vestiture of a marginal fringe around punctured area of fine, long, yellow hair; setae in central area inconspicuous,

conspicuous on epistoma. Pronotum 1.1 times as long as wide; posterior half reticulate, finely punctured; anterior half declivous, asperities rather coarse, extending well behind summit; minute setae (shorter than diameter of a puncture) moderately abundant over entire surface. Elytra 1.5 times as long as wide, 1.5 times as long as pronotum, striae not impressed, punctures small, shallow; interstriae three times as wide as striae, surface smooth, shining, punctures less than half as large as those of striae, uniseriate. Declivity broadly concave, steep; punctures minute, much smaller than on disc, in rows. Vestiture of very minute striae and interstitial hair (each seta shorter than diameter of a puncture).

Distribution: Venezuela: 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 277, *Clusia*, SLW.

Biology: Boring in the phloem of broken twigs.

Notes: The above treatment was based on the type series of 32 specimens.

Scolytodes pilifrons (Schedl)

Scolytodes pilifrons (Schedl), 1962:100 (Hexacolus). Holotype "♂"; Rancho Grande, Maracay, Venezuela; Frey Museum, NHMBS, Basel (References in Wood & Bright c1992:397)

Diagnosis: Median half of middle half of female longitudinal middle half of frons flattened and bearing a marginal (subcircular) fringe of hair, the central area smooth, impunctate; anterior pronotum asperate, interstriae 10 carinate on posterior half, a few setae on odd-numbered interstriae.

Male: Similar to female except frons convex, reticulate, with punctures sparse, coarse.

Female: Length 1.3–1.9 mm, 2.4 times as long as wide, color very dark reddish brown. Frons mostly convex, narrowly flattened on median half of (longitudinal) middle half, flattened area bearing a circular fringe of long hair, its central area smooth, impunctate, glabrous; lateral areas reticulate, with sparse, fine punctures. Pronotum 1.0 times as long as wide; anterior third more steeply declivous, rather coarsely, closely asperate; summit indefinite, some rugae extending to middle of pronotum length; posterior areas reticulate, punctures fine, moderately close. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures in rows, of moderate size near base, becoming much smaller toward base of declivity; interstriae almost smooth, shining, punctures minute, uniseriate. Declivity convex, steep; punctures of striae and interstriae very small, shallow, in rows. Vestiture of sparse rows of erect setae on odd-numbered interstriae, mostly on posterior half; minute rudiments of striae and interstitial setae sometimes evident on and near declivity.

Distribution: Venezuela: 20 km SW El Vigia, Merida, 21-IX-1969, 50 m, No. 144, *Cecropia*, SLW; Rancho Grande, Maracay.

Hosts: Fallen *Cecropia* leaf petioles.

Biology: Tunnels were bored immediately beneath the outer epidermis.

Notes: The above treatment was based on 25 specimens from Venezuela, 2 of which had been compared by me at NHMW, Wien to the female "holotype." According to my notes, the "holotype" in NHMW is a female and, consequently, must be (1) the paratype cited in the original description or (2) the holotype, which had not been returned to the Frey Museum by 1983 and was labeled a male, when in reality it is a female. The problem here is not with the identification of the species but with a determination of which specimen is the holotype and to which sex it belongs.

Scolytodes ficicolens Wood

Scolytodes ficicolens Wood, 1981:126. Holotype ♀; Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:392)

Diagnosis: Female frons with a pair of conspicuous longitudinal carinae very near lateral margin on lower two-thirds of area below upper level of eyes, tuft of hair extending from epistoma to well above upper level of eyes, central area between carinae with minute punctures and fine, short setae.

Male: Similar to female except frons convex, rugose-reticulate, punctures obsolete, subglabrous.

Female: Length 1.7–1.9 mm, 2.7 times as long as wide; color reddish brown. Frons somewhat flattened from epistoma to above upper level of eyes, median two-thirds on slightly more than lower half smooth, shining, very finely punctured, its lateral margins marked by a pair of acute longitudinal carinae; lateral and upper margins closely, finely punctured; vestiture on lateral and dorsal margins of fine, rather long, moderately abundant, yellow hair; central area with very fine, short, sparse hair. Pronotum 1.0 times as long as wide; anterior half declivous, finely, closely asperate, very small rugae extending behind middle; posterior half reticulate, punctures rather small, shallow, close; almost glabrous. Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures moderately small, rather shallow; interstriae almost smooth, shining, punctures shallow, almost as large as those of striae, uniseriate except confused on 2. Declivity convex, steep; as on disc except punctures much smaller. Erect setae on odd-numbered interstriae on declivity, very minute strial and interstitial hair from base to apex (each seta about as long as diameter of a puncture).

Distribution: Venezuela: Merida, Merida, 22-IX-1969, 1700 m, No. 8, *Ficus*, SLW.

Biology: Boring in phloem of branches of a large, uprooted strangler fig.

Notes: The above treatment was based on the type series of 41 specimens.

Scolytodes subcribrosa (Eggers)

Scolytodes subcribrosus (Eggers), 1933:17 (*Hexacolus*). Holotype, sex?; Colonia Tovar, Aragua, Venezuela; MNHN, Paris (References in Wood & Bright c1992:399)

Diagnosis: Female frons moderately concave, without longitudinal carinae; elytra with abundant ground vestiture and with rows of erect setae; pronotum with anterior slope asperate.

Male: Similar to female except frons convex, reticulate, subglabrous.

Female: Length 2.1–2.4 mm, 2.3 times as long as wide; color dark reddish brown. Frons moderately concave on median two-thirds from near epistoma almost to upper level of eyes, concave area almost smooth, impunctate, glabrous; area above concavity to well above upper level of eyes densely, rather finely punctured, a narrow band of punctures extending down lateral margins then transversely across epistoma; punctured area finely pubescent, setae rather short below, very long on dorsal margin. Pronotum 1.0 times as long as wide; anterior half declivous and rather finely, closely asperate, some crenulations extending to one-fourth pronotum length from base; reticulate, punctures on basal third small, moderately close; vestiture of fine, short, moderately abundant hair; much of it abraded on specimens at hand. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures small, close, rather deep; interstriae almost smooth, shining, punctures rather shallow, slightly smaller than those of striae, confused. Declivity broadly convex, steep; sculpture similar to disc except all punctures smaller. Vestiture of rather abundant, short ground strial and interstitial setae (each one to three times as long as diameter of a strial puncture), and rows of erect interstitial bristles (each two-thirds as long as distance between rows), a few extending to base.

Distribution: Colombia: Piedras Blancas 10 km E Medellin, Antioquia, 15-VII-1970, 2500 m, No. 679, *Croton guianensis*, SLW.

Biology: New tunnels were entering phloem of a broken branch 7 cm in diameter.

Notes: The above treatment was based on 2 females, both of which I compared to the female holotype, and on 1 male, all from the same branch in Colombia.

Scolytodes glabrata (Schedl)

Scolytodes glabratus (Schedl), 1954:23 (*Hexacolus*). Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:393)

Diagnosis: Distinguished from *subcribrosa* (Eggers) by the smaller, more slender body form; by the uniseriate interstitial punctures on the disc; and by the strongly reticulate female frons, with setae on the upper and lateral margins much longer.

Male: Similar to female except frons strongly convex, setae restricted to epistomal area.

Female: Length 1.4–1.6 mm, 2.6 times as long as wide; color brown. Frons rather weakly convex from epistoma to slightly above upper level of eyes; surface strongly reticulate on large glabrous area on median two-thirds of lower three-fourths of area below upper

level of eyes, lateral and dorsal margins with a fringe of long, yellow hair, tips of longest setae on dorsal margin capable of extending two-thirds distance to epistomal margin. Pronotum about 1.0 times as long as wide; surface reticulate, anterior third rather strongly declivity and armed by numerous small asperities, some small transverse rugae on disc extending to a point one-third pronotum length from base; punctures on posterior half small, shallow, moderately close; glabrous except several hairlike setae on and near anterior margin. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures small, shallow; interstriae about three times as wide as striae, punctures minute, half as large as those of striae, mostly uniseriate (slight confusion near base in some specimens). Declivity broadly convex, steep; sculpture similar to disc except striae and interstriae narrower, punctures smaller, deeper. Vestiture of sparse rows of erect setae on odd-numbered interstriae (mostly on declivity).

Distribution: Brazil: Nova Teutonia, Santa Catarina, 27°11'B, 52°23'L, 4-XI-1949, 300–600 m, F. Plaumann.

Notes: The above treatment was based on a syntypic series, 4 females (all labeled by Schedl as males) and 5 males (all labeled by Schedl as females) from the Schedl collection at NHMW, Wien. The first specimen in that series, a female (bearing a male label) incorrectly labeled by Schedl as the "type," is here designated as the lectotype of *Hexacolus glabratus* Schedl and is transferred to the genus *Scolytodes*. The specimen in that series, a male (bearing a female label) incorrectly labeled by Schedl as the "type," is here designated as the lectoallotype of *Hexacolus glabratus* Schedl.

Scolytodes morula (Schedl)

Scolytodes morulus (Schedl), 1952:356 (*Hexacolus*). Holotype ♀?; Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:395)

Diagnosis: With the material at hand, this species defies placement in classification. The protibia has a small denticle on the posterior face near the apex, and there are only two denticles between spine 2 and the base; the crest of interstriae 10 continues beyond the level of the hind coxae to the base of the declivity; minute strial setae are present on both disc and declivity; and uniseriate rows of erect interstitial setae are present on both disc and declivity. The holotype is presumed to be a female; if it is not, the position of this species could change radically.

Female (?): Length 1.5 mm, 2.2 times as long as wide; color black. Frons strongly convex on upper half, surface smooth, shining, sparsely, rather finely punctured; flattened on less than lower half, punctures fine, of moderate abundance, vestiture of sparse, fine, short hair. Pronotum 0.91 times as long as wide; dorsal profile rather strongly arched, summit indefinite, at middle; anterior half closely, moderately asperate, punctures obsolete; posterior half almost smooth, shining (feeble

reticulation obscurely indicated in some areas), punctures fine, distinctly impressed, moderately close. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures rather small, moderately impressed, most of those near and on declivity bearing a minute, hairlike seta; interstriae almost twice as wide as striae, surface smooth, shining, punctures small (about one-third as large as those of striae), uniseriate. Declivity broadly convex, steep; striae 1 and 2 weakly impressed. Vestiture of minute strial hair near and on declivity; interstitial setae erect, in uniseriate rows, restricted to declivity and extending cephalad to middle of disc on 1 and 2; each seta slender, length very slightly shorter than distance between rows.

Distribution: Brazil: Nova Teutonia, Santa Catarina, 25-IV-1949, F. Plaumann.

Notes: The above treatment was based on the holotype, presumably a female.

Scolytodes comitabilis Wood

Scolytodes comitabilis Wood, 1978:401. Holotype ♀; Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:390)

Diagnosis: Distinguished from *pusillima* Wood by the darker color; by the strongly reticulate pronotum; by the less distinctly impressed striae 1; and by the sparse interstitial punctures.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 1.4–1.7 mm, 2.7 times as long as wide; mature color almost black. Frons similar to *pusillima* except sparse, short setae always present. Pronotum 1.0 times as long as wide; asperities on anterior slope less numerous, disc strongly reticulate. Elytra about as in *pusillima* except interstitial punctures slightly larger, more widely spaced; strial punctures on declivity distinctly larger; interstitial setae slightly longer, usually absent on anterior half of elytra.

Distribution: Venezuela: Merida, Merida, 22-IX-1969, 1700 m, No. 9, *Clusia*, SLW.

Biology: Boring in phloem of broken branches.

Notes: The above treatment was based on the type series of 17 specimens.

Scolytodes minuta Wood

Scolytodes minutus Wood, 1981:122. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil, 300–500 m, 27°11'B, 52°23'L; NHMW, Wien, replacement name, automatic (Synonymy and references in Wood & Bright c1992:395)

Hexacolus minutissimus Schedl, 1978:297. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil, 300–500 m, 27°11'B, 52°23'L; NHMW, Wien, preoccupied by Schedl 1952:355

Diagnosis: Distinguished from *pusillima* Wood by the smaller size; by the stouter pronotum; by the less strongly impressed discal striae 1; and by the longer, much more slender interstitial setae.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 0.9–1.0 mm, 2.4 times as long as wide; color yellowish brown. Frons similar to *pusillima* except surface weakly, clearly reticulate. Pronotum 1.0 times as long as wide; similar to *pusillima* except much stouter, summit at middle. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; about as in *pusillima* except not as slender, striae 1 feebly impressed on disc, not at all impressed on declivity, erect interstitial setae much stouter, blunt, shorter, length of a seta equal to about two-thirds distance between rows.

Distribution: Brazil: Nova Teutonia, Santa Catarina, VIII-1955, F. Plaumann.

Notes: The above treatment was based on the male holotype and on 7 paratypes of *Hexacolus minutissimus* Schedl (1978:297), preoccupied, that has since been renamed *minuta* Wood.

Scolytodes pusillima Wood

Scolytodes pusillimus Wood, 1981:127. Holotype ♀; Campo Capote 27 km NE Montoya, Santander, Colombia; USNM, Washington (References in Wood & Bright c1992:398)

Diagnosis: Frons convex, subglabrous in both sexes; pronotum smooth, shining; all interstriae with a row of erect setae.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 1.0–1.3 mm, 2.7 times as long as wide; color brown. Frons rather strongly convex from epistoma to vertex; surface reticulate above upper level of eyes, mostly smooth and shining below, punctures small, sparse; subglabrous except fine, sparse setae below level of antennal insertions. Pronotum 1.15 times as long as wide; anterior one-fourth rather strongly declivous, asperate, some indications of reticulation in asperate area; smooth, shining on more than basal half, punctures coarse, deep, close, spaced by diameter of a puncture; glabrous except sparse setae near anterior and lateral margins. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; striae 1 distinctly, others not impressed, punctures rather coarse, deep, close; interstriae about as wide as striae, surface smooth, shining, punctures minute, distinct, uniseriate. Declivity broadly convex, steep; striae 1 rather deeply impressed, striae punctures much smaller, about one-third as large as those on disc. Interstitial setae very slender, each slightly longer than distance between rows.

Distribution: Colombia: Campo Capote 27 km NE Montoya, Santander, 2-VII-1970, 150 m, No. 590, Leguminosae tree, SLW.

Biology: Boring in phloem of branches.

Notes: The above treatment was based on the type series of 84 specimens.

Scolytodes nayaritensis Wood, n. sp.

Scolytodes nayaritensis Wood: Holotype ♂; Laguna Santa Maria, Nayarit, Mexico; USNM, Washington, designated below

Diagnosis: Distinguished from *hagedorni* (Schedl) by having the pronotum summit distinctly anterior to the middle of the pronotum length; by the shorter elytral setae, almost without erect interstitial rows; and by the smaller size. This species is superficially similar to *S. schwarzi* (Hopkins) and may be more closely related to that species; the female is needed to place it accurately.

Male: Length 1.2 mm, 2.5 times as long as wide; color very dark brown, posterior half of elytra light brown. Frons broadly, moderately convex, a weak, transverse impression above epistoma; epistomal margin smooth, shining, upper areas strongly reticulate, punctures small, sparse, mostly obscure; antennal club small, longer than wide, sutures not evident. Pronotum 1.3 times as long as wide; sides straight and parallel on basal two-thirds, rather narrowly rounded in front; anterior margin weakly serrate on median third; summit distinctly anterior to middle of pronotum length; asperities rather coarse, close, confused; posterior areas smooth, shining, punctures rather coarse, deep, close; glabrous. Elytra 1.35 times as long as wide, 1.4 times as long as pronotum; disc occupying basal 70 percent of elytra length; disc smooth, shining, punctures small, distinct, in rows; interstriae twice as wide as striae, punctures half as large as those of striae, mostly in rows. Declivity steep, broadly convex; similar to disc except striae punctures smaller, equal to those of interstriae, rows obscure. Vestiture of abundant short slender setae, mostly of uniform length on declivity and posterior half of disc, setae arising from both striae and interstitial punctures; two or three setae at base of declivity on interstriae 5 and 7 twice as long as ground setae.

Distribution: Mexico (Nayarit).

Type material: The male holotype and 1 male paratype were taken at Laguna Santa Maria, Nayarit, Mexico, 6-VII-1965, 1000 m, No. 198, *Ficus*, SLW. The holotype and paratype are in the U.S. National Museum, Washington.

Scolytodes hagedorni (Schedl)

Scolytodes hagedorni (Schedl), 1962:101 (*Prionosceles*). Holotype ♀; Mirador, Ecuador, 3800 m; NHMW, Wien (References in Wood & Bright c1992:393)

Diagnosis: Distinguished from *perpusilla* Wood and *parva* (Eggers) by the slightly larger size; by the pronotum being slightly longer than wide, and the near absence of reticulation on the basal half; and by the distinctly larger striae punctures.

Male: Similar to female except median crest on upper frons to vertex slightly more definite; punctures on declivity larger.

Female: Length 1.7–2.0 mm, 2.3–2.4 times as long as wide; color very dark brown. Frons rather strongly convex, reticulate, punctures rather fine, moderately close, median line impunctate on upper half, slightly elevated at epistoma (not carinate); vestiture of fine, sparse hair, mostly at and near epistoma. Pronotum 1.0 times as long

as wide; summit definite, apparently behind middle; surface mostly smooth, shining, reticulation obscure, irregular; anterior slope on anterior third, with small, isolated asperities replacing punctures; punctures on basal half small, rather close; vestiture apparently abraded, paratype with rather abundant setae of moderate length. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures rather coarse, in rows; interstriae slightly more than twice as wide as striae, punctures half as large as those of striae, uniseriate. Declivity broadly convex, steep; striae 1–3 in identifiable rows on upper half, punctures greatly reduced in size; all punctures confused on lower half and laterally. Vestiture mostly abraded on type, on paratype both striae and interstitial setae present from base to apex, striae hair rather short, interstitial setae longer, equal in length to half to two-thirds width of an interstriae, very slightly longer on declivity.

Distribution: Ecuador: Mirador, 3800 m, 1903, P. Rivet (type); Chiles, 4150 m, 1903, P. Rivet (paratype); El Angel, Carchi, 13-IX-1973, 3400 m, *Espeletia hartwegiana* leaves and flowers.

Notes: The above treatment was based on the female holotype and on 1 female paratype, both from Ecuador, and on a long series of non-type specimens from Ecuador.

Scolytodes parva (Eggers)

Scolytodes parvus (Eggers), 1943:371 (*Hylocurosoma*). Holotype ♀?; Cochabamba; USNM, Washington (References in Wood & Bright c1992:397)

Diagnosis: Distinguished from *perpusilla* Wood by the much more slender body form; by the larger striae and interstitial punctures; and by the much longer elytral setae.

Female (?): Length 1.6 mm, 2.6 times as long as wide; color yellowish brown (callow?). Frons convex, without a carina, vestiture sparse (not fully visible on type due to strong angle of observation); median crest from upper level of eyes to vertex weakly elevated. Pronotum 1.0 times as long as wide; summit indefinite, near middle, anterior slope weakly asperate, asperities very small, isolated, serrations on anterior margin feeble; posterior areas weakly reticulate, punctures moderately coarse, close; vestiture of fine rather long, abundant hair. Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures in rows, rather coarse, deep, each slightly more than half as wide as an interstriae; interstriae less than twice as wide as striae, smooth, shining, punctures almost as large as those of striae, rather deep, uniseriate. Declivity broadly convex, steep; striae and interstitial punctures slightly smaller than on disc, in rows. Vestiture of moderately long striae hair and long to very long interstitial hair, rather abundant, some interstitial setae twice as long as distance between rows.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the holotype from Bolivia, presumably a female.

Scolytodes perpusilla Wood

Scolytodes perpusillus Wood, 1978:404. Holotype ♀; Rancho Grande, Pittier National Park, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:397)

Diagnosis: Frons similar in male and female; interstriae 10 obsolete on posterior half; distinguished from *crinita* Wood by the smaller punctures on the pronotum disc and by the shorter elytral hair.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 1.0–1.4 mm, 2.3 times as long as wide; color very dark brown. Frons convex from level of antennal insertions to vertex; surface mostly reticulate, weak on lower half, punctures rather fine, deep, not close; vestiture confined to lower half, sparse, fine; median line above eyes with special sculpture. Pronotum 1.0 times as long as wide; anterior third declivous, asperities minute, isolated; surface reticulate, moderately close, coarse, deep, a few punctures of reduced size almost attaining anterior margin; vestiture rather short, moderately abundant, covering entire surface. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures in rows, moderately large near base, small at base of declivity; interstriae twice as wide as striae, surface smooth, shining; punctures half as large as those of striae, uniseriate. Declivity broadly convex, steep; punctures small, confused, striae not discernible. Vestiture of fine striae and interstitial hair, striae setae one-third as long as distance between rows, semi-recumbent, interstitial setae partly semirecumbent, partly of erect interstitial rows, each seta about two-thirds as long as distance between rows.

Distribution: Venezuela: El Laurel Experimental Farm 12 km SW Caracas, 1-V-1970, 1300 m, No. 443, in tree branch (1 specimen), No. 464 in Leguminosae vine, SLW.

Hosts: Tree branch (accidental?), Leguminosae vine.

Biology: Boring in phloem of a broken branch and of a cut vine.

Notes: The above treatment was based on the type series of 98 specimens.

Scolytodes crinita Wood

Scolytodes crinitus Wood, 1978:402. Holotype ♀; El Laurel Experimental Farm 12 km SW Caracas, Venezuela; USNM, Washington (References in Wood & Bright c1992:391)

Diagnosis: Distinguished from *perpusilla* Wood by the larger punctures on the pronotum disc; by the larger striae and interstitial setae; and by the larger setae on the female frons.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 1.3–1.5 mm, 2.3 times as long as wide; color very dark reddish brown. Frons convex,

reticulate, finely, shallowly, sparsely punctured from slightly above level of antennal insertions to vertex; weakly, narrowly flattened on and near epistoma; vestiture of sparse, fine hair on less than lower half of frons. Pronotum about 1.0–1.06 times as long as wide; anterior third moderately declivous, asperities small, mostly isolated; surface reticulate, subshining, punctures small, shallow, moderately close; vestiture short, fine, inconspicuous, about uniformly distributed. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures fine on basal third of disc, minute near declivity; interstriae about three times as wide as striae near base, about five times as wide at base of declivity, surface smooth, subshining, punctures distinctly smaller than those of striae. Declivity broadly convex, steep; punctures abundant, somewhat obscure, strongly confused. Vestiture of moderately abundant, very short striae and interstitial hair (each about one to three times as long as diameter of a striae puncture), and uniseriate rows of erect setae almost to base on all interstriae, those on declivity almost as long as distance between rows, mostly shorter on disc.

Distribution: Venezuela: Rancho Grande, Aragua, 9-IV-1970, 100 m, No. 443, tree branch, SLW; El Laurel Experimental Farm 12 km SW Caracas, 1-V-1970, 1300 m, No. 464, Leguminosae vine, SLW.

Hosts: Unidentified tree, and Leguminosae vine.

Biology: Boring in phloem tissues of small stems.

Notes: The above treatment was based on the type series of 71 specimens.

Scolytodes adusta (Eggers)

Scolytodes adustus (Eggers), 1943:368 (*Hylocurosoma*). Holotype ♀?; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:388)

Diagnosis: Distinguished from *limbata* (Eggers) by the absence of a median frontal elevation; by the strongly reticulate pronotum disc; and by the uniseriate interstitial punctures from the base to the base of the declivity.

Female (?): Length 1.7 mm, 2.4 times as long as wide; color very dark reddish brown. Frons very broadly convex (without a median carina), surface rugose-reticulate, somewhat longitudinally etched below, punctures small, irregularly distributed; a weak, broadly U-shaped, subcarinate elevation extending from antennal insertions obliquely to epistoma; vestiture minute, very short, sparse. Pronotum 1.0 times as long as wide, widest on basal half; anterior half finely asperate, asperities small, isolated, anterior margin not serrate; summit indefinite; posterior half strongly reticulate, punctures rather coarse, deep. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures rather small, deep, spaced within a row by diameter of a puncture; interstriae slightly more than twice as wide as striae, punctures small, uniseriate from base to apex of declivity. Declivity broadly convex, steep; striae punctures

smaller than on disc, in rows, interstitial punctures about as large as on disc, uniseriate.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the holotype from Bolivia, presumed to be a female.

Scolytodes limbata (Eggers)

Scolytodes limbatus (Eggers), 1943:370 (*Hylocurosoma*). Holotype ♂?; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:394)

Diagnosis: Distinguished from *libida* Wood by the absence of a carina on the lower frons; by reduced reticulation on the pronotum disc, with the punctures larger, closer; by the smaller, closer striae punctures; and by the minute interstitial punctures.

Male (?): Length 1.8 mm, 2.4 times as long as wide; color very dark brown, parts of elytra medium brown. Frons convex, somewhat flattened on lower two-thirds, upper area almost smooth, shining, rather coarsely, closely, deeply punctured, median line distinctly elevated to upper level of eyes; lower areas smooth, shining, punctures rather fine near epistoma; vestiture fine, sparse above, more abundant on and near epistoma. Pronotum 1.0 times as long as wide, widest on basal third; anterior half rather coarsely, closely asperate, anterior margin obscurely subserrate; posterior half irregularly, weakly reticulate, punctures rather coarse, deep, close; vestiture of fine, rather short, moderately abundant hair. Elytra 1.5 times as long as wide; striae 1 feebly, others not impressed, punctures rather small, moderately deep, close; interstriae slightly more than twice as wide as striae, smooth, shining, punctures minute, uniseriate on more than anterior half of disc, weakly to moderately confused near base of declivity. Declivity broadly convex, steep; striae punctures smaller than on disc, distinctly impressed, in rows; interstitial punctures minute, weakly to strongly confused. Vestiture partly abraded on type; short striae setae present (at least on declivity), interstitial hair fine, rather short on disc, longer on declivity (longest setae slightly shorter than distance between striae rows), somewhat irregular.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the holotype from Bolivia, presumably a male.

Scolytodes confusa (Eggers)

Scolytodes confusus (Eggers), 1943:370 (*Hylocurosoma*). Holotype ♀?; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:390)

Diagnosis: Distinguished from *ater* (Eggers) by the smaller punctures on the pronotum disc; and by the smaller striae punctures on the disc, the interstitial punctures almost as large, much more numerous and very strongly confused from base to base of declivity.

Female (?): Length 2.1 mm, 2.4 times as long as wide; color medium brown, obviously callow. Frons similar to

gennaea Wood except carina much longer, from epistoma to upper level of eyes (seen with difficulty on type from a strong angle of observation). Pronotum 1.0 times as long as wide, surface reticulate, asperities on anterior half very small, isolated; punctures on disc small, close, most with a minute shining spot on rim; vestiture of very fine, rather long hair of moderate abundance. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures small, in scarcely discernible rows on basal half only; interstriae about three or four times as wide as striae, surface smooth shining, punctures small, half as large as those of striae near base (about equal in size toward declivity), rather numerous, very strongly confused from base to base of declivity. Declivity broadly convex, steep; surface almost smooth, shining, punctures very small, numerous, confused. Vestiture of abundant, fine strial and interstitial setae of moderate length on disc and declivity.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the holotype from Bolivia, presumably a female.

Scolytodes ater (Eggers)

Scolytodes ater (Eggers), 1943:365 (*Prionosceles*). Holotype ♀?; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:389)

Hylocurosoma elongatum Eggers, 1943:369. Lectotype ♀; Cochabamba, Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:12, preoccupied by Schedl 1935:273

Scolytodes elongatissimus Wood, 1988:32. Lectotype ♀; Cochabamba, Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:12, replacement name, automatic (References in Wood & Bright c1992:391). *New synonymy*

Diagnosis: Distinguished from *gennaea* Wood by the smooth, shining surfaces near and on the declivity (not shagreened); by the slightly larger, less abundant declivital punctures; and by the less abundant vestiture of irregular length.

Female (?): Length 2.1 mm, 2.5 times as long as wide; color almost black. Frons as in *gennaea* except median elevation slightly shorter. Pronotum as in *gennaea* except only a few punctures on posterior half behind summit with a shining spot on their rim (almost all punctures in *gennaea* with this spot). Elytra about as in *gennaea*, except surface near and on declivity smooth and shining as on anterior disc (shagreened or rather dull in *gennaea*); punctures on declivity slightly larger, less regular in size, and less abundant than in *gennaea*. Declivital setae longer and less regular in length.

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the lectotype of *Prionosceles ater* Eggers, an apparent female, and on the female lectotype and 2 female cotypes of *Hylocurosoma elongatus* Eggers. This species is very close to *libida* Wood; future collecting could eventually result in the placement of the junior name in synonymy.

Scolytodes gennaea Wood

Plate LI

Scolytodes gennaeus Wood, 1988:33. Holotype ♀; 30 km N Merida, Merida, Venezuela; USNM, Washington, replacement name, automatic (References in Wood & Bright c1992:392)

Scolytodes genialis Wood, 1978:403. Holotype ♀; 30 km N Merida, Merida, Venezuela; USNM, Washington, preoccupied by Wood 1975:27 (References in Wood & Bright c1992:392)

Diagnosis: Distinguished from *libida* Wood by the smaller and more restricted pronotal asperities; by the slightly flattened upper elytral declivity; and by the presence of reticulation on the frontal carina to its summit.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 1.9–2.4 mm, 2.3 times as long as wide; mature color almost black. Frons rather strongly convex from epistoma to vertex; surface strongly reticulate, punctures very small, rather shallow, moderately close; median line from epistoma to slightly above level of antennal insertions rather strongly, subacutely carinate, its crest smooth, shining; vestiture confined to lower half, of fine, sparse, inconspicuous hair. Pronotum 1.15 times as long as wide; moderately declivous in front, anterior half with small, subasperate, isolated granules, decreasing posteriorly, shining margins of punctures continue to base; punctures small, shallow, moderately close, clearly evident on posterior half, becoming obsolete slightly anterior to middle; vestiture of moderately abundant, fine, short hair, about uniformly distributed. Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures small, shallow, in rows; interstriae about three times as wide as striae, surface smooth, shining, punctures about half as wide as those of striae, some uniseriate near base, all confused by middle of disc. Declivity broadly convex, steep; striae 1 and 2 with reduced punctures in rows near base, all strial and interstitial punctures small and confused elsewhere. Vestiture of fine, semirecumbent, rather long hair, erect rows of interstitial setae obscurely indicated, not clearly evident.

Distribution: Venezuela: 30 km N Merida, Merida, 8-I-1970, 2200 m, No. 224, Cucurbitaceae vine, SLW.

Biology: Boring in cut vines 1–4 cm in diameter.

Notes: The above treatment was based on the type series of 113 specimens from Venezuela.

Scolytodes libida Wood

Scolytodes libidus Wood, 1978:404. Holotype ♀; Rancho Grande, Pittier National Park, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:394)

Diagnosis: Distinguished from *gennaea* Wood by the larger, more extensive pronotal asperities; by the more uniformly confused punctures on upper declivity; and by the smooth, shining frontal carina.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 1.7–1.9 mm, 2.4 times as long as wide; mature color almost black. Frons as in *gemmaea* except punctures distinctly larger, carina reticulate to summit, resembling *gemmaea* except asperities on anterior slope slightly larger, confined to anterior half, punctures not extending into asperate area; punctures on posterior area devoid of shining spot on margins. Elytra as in *gemmaea* except striae 1 and 2 reduced, not clearly evident on declivity, all punctures confused.

Distribution: Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 407, Cucurbitaceae vine, SLW.

Biology: Boring in stems of cut vines.

Notes: The above treatment was based on the type series of 57 specimens.

Scolytodes tolimana (Schedl)

Scolytodes tolimanus (Schedl), 1962:102 (*Prionosceles*). Holotype ♂; Nevado del Tolima, Colombia; NHMW, Wien (References in Wood & Bright c1992:400)

Diagnosis: Distinguished from *constricta* Wood by the confused punctures on discal interstriae 2 and 3; by the less strongly narrowed basal half of the pronotum; and by the distinctly shorter elytral setae.

Male: Length 2.8 mm, 2.8 times as long as wide; color black. Frons rather broadly convex; a low, acute median carina from epistoma almost half distance to upper level of eyes; surface strongly reticulate, punctures rather coarse, close, moderately deep; vestiture of sparse, fine, rather short hair above, longer on lower fourth. Pronotum 1.0 times as long as wide; widest at middle, slightly narrower toward base; asperities on anterior half very small, isolated, some weakly subvulcanate near summit; posterior areas clearly, rather weakly reticulate, punctures rather small, close, a few with a small, shining spot on margin; vestiture of fine, long, moderately abundant hair. Elytra about 1.8 times as long as wide, 1.8 times as long as pronotum (elytra of type spread, 1 elytron broken); striae 1 weakly impressed, 2 and 5 not impressed, 1–5 with punctures in rows, rather small, impressed (others mostly confused with interstriae); interstriae about three times as wide as striae, mostly smooth, shining, punctures on 1–3 fine, deep, confused, each about one-third as large as those of striae. Declivity broadly convex, steep; striae obsolete, all punctures very small, confused. Vestiture of moderately long strial hair; interstitial hair moderately abundant, some equal in length to 1.5 times width of an interstriae, apparently shorter on declivity.

Distribution: Colombia: [Nevado del] Tolima, 4000 m [Dep. Tolima].

Notes: The above treatment was based on the male holotype from Colombia.

Scolytodes constricta Wood

Plate L

Scolytodes constrictus Wood, 1977:518. Holotype ♀; Piedras Blancas 11 km W Medellin, Antioquia, Colombia; USNM, Washington (References in Wood & Bright c1992:391)

Diagnosis: Pronotum conspicuously longer than wide, distinctly wider on anterior third, the asperities on the anterior slope much smaller, not attaining summit; setae on pronotum and elytra of very fine, unusually long hair; body very slender; pronotum constricted on posterior half.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 2.4–2.8 mm, 3.0 times as long as wide; color very dark brown, vestiture very long. Frons moderately convex from epistoma to upper level of eyes, more strongly convex above eyes, surface reticulate, punctures fine, moderately close, shallow, a feeble median elevation extending dorsad from center of frontal rectangle, becoming lower and broader by vertex; vestiture sparse, about uniformly distributed from epistoma to slightly below upper level of eyes, of fine, very long hair. Pronotum 1.2 times as long as wide, conspicuously wider on anterior third, posterior half with sides distinctly (concavely) constricted before base; asperities small, isolated, moderately numerous, decreasing in size and numbers then obsolete before summit; surface reticulate; punctures on posterior half small, deep, moderately close; vestiture of fine, very long hair of moderate abundance. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures very small; interstriae smooth, shining, punctures smaller than those of striae, almost all uniseriate. Declivity broadly convex, steep; punctures as on disc except smaller. Vestiture of very fine, long hair on striae and interstriae, those on disc equal in length to width of an interstriae, up to three times as long on declivity.

Distribution: Colombia: Piedras Blancas 11 km W Medellin, Antioquia, 17-VII-1970, 2300 m, No. 688, “*Baccharus*,” SLW.

Biology: Boring in the phloem of broken branches.

Notes: The above treatment was based on the type series of 29 specimens. The host shrub name was given by a local botanist as “*Baccharus*”; this name is apparently incorrect but superficially does resemble that genus.

Scolytodes contracta Wood

Scolytodes contractus Wood, 1977:518. Holotype ♀; 13 km SE El Vigia, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:391)

Diagnosis: Distinguished from *constricta* Wood by the larger pronotal asperities and punctures; by the much coarser, deeper strial punctures; and by the minute interstitial punctures.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 2.6–3.0 mm, 2.8 times as long as wide; color reddish brown, anterior half of pronotum and elytral declivity sometimes much darker. Frons about as in *constricta* except punctures much coarser. Pronotum about as in *constricta* except asperities distinctly larger,

posterior areas mostly smooth, shining, reticulation restricted, punctures on disc much larger, closer, deeper. Elytra similar to *constricta* except striae punctures much larger, deeper, interstriae twice as wide as striae, punctures minute, uniseriate, vestiture almost as long, slightly less abundant.

Distribution: Venezuela: 13 km SW El Vigia, Merida, 22-X-1969, 100 m, No. 95, unidentified liana, SLW.

Biology: Boring in phloem of a cut liana.

Notes: The above treatment was based on the type series of 36 specimens.

Scolytodes varia Wood

Plate LVIII

Scolytodes varius Wood, 1977:522. Holotype ♀; La Mucuy, 20 km W Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:400)

Diagnosis: Distinguished from *contracta* Wood by the more strongly flattened, more closely punctured frons with a rather large, smooth, impunctate, median area on lower half; by the more strongly reticulate pronotal disc; and by the much longer elytral setae.

Male: Similar to female, distinguished by abdominal terga 7 and 8.

Female: Length 2.7–3.2 mm, 2.5 times as long as wide; color very dark brown (almost black), except pale brown from elytral striae 1 to about 5 or 7 from base to apex. Frons broadly flat to almost planoconcave from epistoma to upper level of eyes, a central fovea usually present, very closely, rather coarsely, deeply punctured, median fourth from fovea to epistoma smooth, shining, impunctate; surface of dorsal half reticulate; vestiture of moderately abundant, very long hair. Pronotum 1.2 times as long as wide; similar to *contracta* except surface of disc reticulate. Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures rather small, deep; interstriae four times as wide as striae, smooth, shining, punctures two-thirds as large as those of striae, rather deep. Declivity broadly convex, steep; punctures slightly smaller than those on disc. Vestiture of very long, fine striae and interstitial hair; some setae equal in length to combined width of three interstriae.

Distribution: Venezuela: 30 km E Merida, Merida, 8-I-1970, 2500 m, No. 220, *Croton*, SLW; La Mucuy 20 km W Merida, Merida, 12-XI-1969, 2500 m, No. 129, tree branch, SLW; Merida, Merida, 20-I-1987, T. Weslein.

Hosts: *Croton* sp., etc.

Biology: Boring in phloem of broken branches.

Notes: The above treatment was based on the type series of 120 specimens and on 1 other specimen, all from Venezuela.

Scolytodes atrotibialis (Eggers)

Scolytoes atrotibialis (Eggers), 1943:365 (*Prionosceles*). Holotype ♂; Cochabamba, Bolivia; MNHN, Paris (References in Wood & Bright c1992:389)

Diagnosis: Elytral interstriae 10 not elevated or marked by rows of adjacent striae punctures, elytral punctures dense, confused from base to apex, vestiture abundant, recumbent, of uniform length (without rows of longer interstitial setae); pronotum with numerous small asperities on anterior two thirds.

Male: Length 2.3 mm, 2.2 times as long as wide color of pronotum reddish brown, elytra reddish brown (mature?). Frons weakly convex from vertex to near level of antennal insertion, then almost flat to epistoma; surface reticulate, punctures small, rather numerous, uniformly distributed; vestiture of fine moderately long setae from epistoma to upper level of eyes (concealed above on type by pronotum); antennal club small, oval, suture 1 obscure. Pronotum 1.0 times as long as wide; sides and anterior margin about equally arcuate; summit indefinite, on basal fourth of pronotum length, surface reticulate, armed on anterior three-fourths from side to side by numerous, confused, very small asperities, with small, close punctures on basal fourth; vestiture of abundant short recumbent setae uniformly distributed. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; disc occupying 55 percent of elytra length; surface from base to apex smooth, shining, with numerous, close, confused punctures. Declivity convex, moderately steep, a weak narrowly impressed groove in position of striae 1 from base to near apex of declivity. Vestiture of uniformly short, recumbent, confused setae.

Distribution: Bolivia: Cochabamba, Germain, 1907, Donckier.

Notes: The above treatment was based on the male holotype.

Scolytodes pilosula (Eggers), n. comb.

Plate LVII

Scolytodes pilosulus (Eggers), 1932:234 (*Problechilus*). Holotype, sex?; Cochabamba, Bolivia; USNM, Washington (Wood & Bright c1992:387)

Diagnosis: Allied to *pilifer* Wood and *schoenmanni* Wood, but smaller and with shorter erect setae on interstriae 1–9; by having the pronotum summit on the basal third of the pronotum length, the anterior slope gradual; and by the elytral disc occupying the basal 60 percent of the elytra length, the ground vestiture abundant, hairlike, rather long.

Male: Length 2.2 mm, 2.1 times as long as wide; color reddish brown. Frons shallowly concave on upper half to upper level of eyes, surface partly rugose-reticulate, lower half broadly flattened, surface subreticulate, minute punctures obscure. Pronotum 0.84 times as long as wide; widest on basal third, sides moderately arcuate, rather broadly rounded in front; anterior margin armed by about 8 coarse, irregular serrations; summit two-thirds pronotum length from anterior margin, anterior slope rather coarsely asperate on median 80 percent; basal fourth very closely, finely punctured, almost granulate in some areas, vestiture of short hair on asperate area.

Elytra 1.3 times as long as wide; disc occupying basal 50–60 percent of elytra length (gradual transition); striae not impressed, punctures small, shallow; interstriae four times as wide as striae, surface almost smooth, punctures minute, dense, confused. Declivity broadly convex, moderately steep; sculpture resembling disc, except striae 1–3 weakly impressed, punctures conspicuously larger; interstriae 1–3 weakly convex, one to two times as wide as striae, without any tubercles. Vestiture of (1) abundant, short, hairlike ground cover (longest setae equal in length to half width of an interstriae), and (2) uniseriate rows of erect interstitial bristles on all interstriae, their positioning not regular, most setae slightly shorter than width of an interstriae.

Distribution: Bolivia: Cochabamba [Woytkowski].

Note: The above treatment was based on the male holotype from Bolivia.

Scolytodes schoenmanni Wood, n. n.

Plate LVIII

Scolytodes schoenmanni Wood: Holotype ♂; Marcapata, Peru; NHMW, Wien, automatic, replacement name for *Problechilus glaber* Schedl *Problechilus glaber* Schedl, 1951:87. Holotype ♂; Marcapata, Peru; NHMW, Wien, preoccupied by *Hexacolus glaber* Eichhoff 1868:400 (References in Wood & Bright c1992:386)

Diagnosis: Allied to *varia* Wood and *opaca* Wood, distinguished by the stout body form; by the presence of striae punctures in rows from base to apex; and by the dense, small, deep interstitial punctures with no tubercles on either disc or declivity.

Male: Length 2.6 mm, 2.0 times as long as wide; color almost black except basal fourth of pronotum dark reddish brown. Frons broadly, shallowly concave from epistoma to well above upper level of eyes, apparently reticulate, with sparse, shallow, obscure punctures; vestiture of fine, short, rather sparse hair. Antennal funicle 6-segmented, club about as in allied species. Pronotum 0.82 times as long as wide; widest at middle of pronotum length, sides strongly arcuate to rather broadly rounded anterior margin; anterior margin armed by 6 weak serrations; summit indefinite, three eighths of pronotum length from base, anterior slope closely, rather coarsely asperate, basal area densely, finely, rugosely punctured with some reticulation; vestiture of short, hairlike setae on asperate area. Elytra 1.2 times as long as wide, 1.6 times as long as pronotum; disc occupying slightly less than basal two-thirds of elytra length; striae 1 and part of 2 weakly impressed on disc and more densely impressed on declivity, punctures very small, shallow; interstriae on disc about six times as wide as striae, shining, punctures small, dense, deep, confused, distinctly narrower on declivity; setiferous punctures on discal interstriae mostly larger, occasionally feebly granulate. Vestiture of abundant ground cover of fine, short hair of uniform length, and uniseriate, irregular interstitial rows on disc of long, slender bristles, those on odd-numbered interstriae equal in length to combined width of one or two interstriae, those on even-numbered interstriae less numerous and about half as long.

Distribution: Peru: Marcapata.

Notes: This species is here transferred from *Problechilus* to *Scolytodes* to which it clearly belongs. Because the name *glaber* is preoccupied by Eichhoff (1868:400), a new replacement name, *schoenmanni*, is presented above for *Hexacolus glaber* Schedl. The above treatment is based on the male holotype.

Scolytodes laevicollis (Eggers), n. comb.

Plate LIII

Scolytodes laevicollis (Eggers), 1932:230 (*Problechilus*). Holotype ♂; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1991:386)

Diagnosis: Distinguished from *brevis* (Eggers) by the weakly serrate anterior margin of the declivity; by the much more widely distributed asperities on the pronotum (100 percent of pronotum width); and by having long, erect bristles on interstriae 1 and 3 to 9.

Male: Length 3.3 mm, 1.9 times as long as wide; color dark reddish brown. Frons rather narrow above eyes, separated by 2.5 times width of an eye, weakly convex, lower half irregularly convex and with lateral margins weakly, subacutely elevated, surface weakly reticulate, with sparse punctures; almost glabrous. Pronotum 0.80 times as long as wide; widest at middle, sides strongly arcuate, broadly rounded in front; anterior margin armed by six feeble serrations; summit indefinite, on basal half; anterior two-thirds finely, closely asperate over 100 percent of pronotum width; basal fourth obscurely reticulate, densely, finely punctured (almost granulate); vestiture of short, stout recumbent hair on asperate area. Elytra 1.16 times as long as wide, 1.5 times as long as pronotum; disc occupying posterior half of elytra length; striae distinctly impressed, punctures in rows, rather large, deep; interstriae weakly convex, two to three times as wide as striae, surface with dense, confused, very small punctures that bear ground setae, sparse punctures bear erect bristles. Declivity broadly convex, moderately steep; sculpture as on disc. Vestiture of abundant ground setae, those at base of elytra slender, rather long, those on and near declivity much shorter, each about six times as long as wide; and long erect interstitial bristles on disc and sides, two or more bristles present on 1 and 3–9, each bristle equal in length to 1.0–1.5 times width of an interstriae; erect bristles on declivity either broken or in process of being lost (occasional remnants present).

Distribution: Bolivia: Cochabamba (type, det. Eggers 1932).

Notes: The above treatment was based on the male holotype.

Scolytodes brevis (Eggers), n. comb.

Plate XLVIII

Scolytodes brevis (Eggers), 1932:231 (*Problechilus*). Holotype ♂; Cochabamba, Bolivia; USNM, Washington (References in Wood & Bright c1992:386)

Diagnosis: Distinguished from *schoenmanni* Wood by the absence of a row of long setae on odd-numbered interstriae; by the larger size; and by other features described below.

Male: 3.3 mm, 1.8 times as long as wide; very dark brown. Frons convex, a weak impression on median third at upper level of eyes; lower half of frons almost flat; surface reticulate, minute punctures obscure, vestiture sparse. Pronotum 0.77 times as long as wide; widest on basal third, sides arcuately converging toward rather narrowly rounded anterior margin; anterior margin armed by 12 coarse serrations; summit 60 percent of pronotum length from anterior margin, anterior slope rather coarsely, closely asperate on median half; most areas covered by a dense ground cover of confused, minute setae, a few longer bristles near lateral and anterior margins. Elytra 1.04 times as long as wide, 1.4 times as long as pronotum; disc occupying basal 40 percent of elytra length; striae weakly impressed, punctures small, shallow, in definite rows; interstriae about five times as wide as striae, punctures of two kinds: (1) dense micropunctures bearing small ground setae; and (2) larger, bristle bearing punctures on odd-numbered interstriae. Declivity very broadly convex, gradual; sculpture about as on disc. Vestiture of dense microsetae, each about four times as long as wide and length about equal to one-tenth width of an interstriae, and erect bristles on odd-numbered interstriae in sparse rows, longest bristles slightly longer than width of an interstriae, even-numbered interstriae without any erect bristles.

Distribution: Bolivia: Cochabamba (type).

Notes: The above treatment was based on the male holotype.

Scolytodes opaca Wood

Plate LV

Scolytodes opacus Wood, 1977:520. Holotype ♀; Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:396)

Scolytodes opimus Wood, 1977:520. Holotype ♀; La Carbonera Experimental Forest 50 km airline NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:396). *New synonymy*

Diagnosis: Distinguished by the broadly impressed, gradual declivity that occupies more than half of the elytra length; by striae 1 and 3 to about 7 indicated, 2 obsolete in male, almost so in female, punctures between 1 and 3 confused, finely tuberculate; body size very large for this genus.

Male: Similar to female, except striae 2 obsolete, tubercles on elytral disc larger.

Female: Length 2.7–3.5 mm, 2.1 times as long as wide; color rather dark reddish brown. Frons moderately convex from epistoma to upper level of eyes, small fovea below center, reticulate below fovea, rugose-reticulate from fovea to vertex, punctures very small, rather sparse; vestiture of fine hair, very sparse from epistoma to above upper level of eyes, slightly more numerous near

epistoma. Pronotum 1.0 times as long as wide; anterior half rather coarsely, closely asperate, small crenulations of decreasing height continue almost to base; surface strongly reticulate, punctures small, close, deep; vestiture of rather abundant, moderately long, recumbent, fine hair. Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; striae 1–3 usually visible on basal third of disc, punctures minute, confused behind with those of interstriae, some interstitial punctures tuberculate; surface smooth, shining. Declivity occupying at least posterior half, rather gradual, very broadly convex, striae 1 less strongly impressed, median half feebly flattened; punctures minute to obsolete. Vestiture of abundant striae and interstitial setae, most setae shorter than distance equal to width of an interstriae, a few on lateral area of basal half of declivity much longer and rather coarse.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 9 XII-1969, 2500 m, No. 172, large liana, SLW; Merida, Merida, between Teleferico stops 2 and 3, 27 II-1970, 2500 m, No. 331, tree bole, SLW.

Hosts: Large liana; bole of tree with very large leaves.

Biology: Boring in phloem tissues.

Notes: The above treatment was based on the type series of *opimus* of 30 specimens, and on the type series of 96 specimens of *opacus*.

Scolytodes vicina (Eggers)

Scolytodes vicinus (Eggers), 1928:87 (*Prionosceles*). Holotype ♀; Petropolis, Rio de Janeiro, Brazil; SMTD, Dresden (References in Wood & Bright c1992:400)

Prionosceles dubiosus Schedl, 1972:55. Holotype ♀; S. Bocaina, Brazil, S.J. Berreira, 1650 m; NHMW, Wien (References in Wood & Bright c1992:391). *New synonymy*

Diagnosis: Distinguished from *argentinensis* (Eggers) by the continuation of striae 1–3 to base of declivity, 1 very strongly, 2 weakly impressed, their punctures indicated; and by the slightly larger interstitial punctures on the posterior disc.

Female: Length 3.0–3.2 mm, 2.1 times as long as wide; color black. Very similar to *argentinensis* except striae 1–3 indicated on posterior two-thirds of disc, 1 very strongly impressed, 2 feebly impressed, 3 obscurely impressed, punctures very small, distinctly impressed; interstitial punctures on posterior half of disc distinctly larger than in *argentinensis*. Frons with a median callus extending from upper level of eyes to vertex (a very short callus well above eyes in *argentinensis*), significance of this character cannot be ascertained until more specimens are available for study.

Distribution: Brazil: Petropolis, Rio de Janeiro, 1, 1907, Dr. Ohaus; S. Bocaina, S.J. Barreiro, S.P., XI-1969, Seabra & Alvarenga.

Notes: The above treatment was based on the female holotype of *Prionosceles vicinus* Eggers from Petropolis, and on the female holotype of *Prionosceles dubiosus* Schedl from S. Bocaina, S.J., in Brazil. Additional material

must be studied to determine whether this species is distinct from the very closely allied *argentinensis* (Eggers).

Scolytodes argentinensis (Eggers)

Scolytodes argentinensis (Eggers), 1928:87 (*Prionosceles*). Lectotype ♀?; Argentina; USNM, Washington, designated by Anderson & Anderson 1971:4 (References in Wood & Bright c1992:388)

Diagnosis: Distinguished from *opaca* Wood by the absence of elytral tubercles on both disc and declivity; elytra uniformly rather short, semirecumbent, without any long setae.

Female (?): Length 3.1 mm, 2.0 times as long as wide; color almost black. Frons moderately convex, strongly reticulate above eyes, more finely reticulate below; punctures small, shallow; a median fovea present; vestiture very fine, short, uniformly distributed, obscure. Pronotum 0.94 times as long as wide; surface strongly reticulate from base to anterior margin, less than basal half rather finely, moderately punctured, more than anterior half moderately, closely asperate (each cusp shining, not reticulate), decreasing behind and gradually replaced by punctures; vestiture fine, short, apparently, moderately abundant (abraded). Elytra 1.1 times as long as wide, 1.3 times as long as pronotum; striae 1–3 obscurely indicated on basal fourth, because punctures slightly larger and in indistinct rows; surface smooth, shining (no tubercles), punctures fine to moderately coarse, confused, rather abundant, becoming minute one-fourth elytral length from base. Declivity occupying posterior half of elytral length, broadly convex, gradual; striae 1 rather strongly impressed (its punctures not evident); surface smooth, shining, punctures minute, each about equal in diameter to diameter of a seta; vestiture abundant, confused from apex to base, setae equally very slender on disc and declivity; all setae rather short, semirecumbent, without any long bristles.

Distribution: Argentina: "Argentina."

Notes: The above treatment was based on the lectotype from Argentina, presumably a female.

Scolytodes similis (Eggers)

Scolytodes similis (Eggers), 1928:87 (*Prionosceles*). Lectotype ♀; Argentina; USNM, Washington, designated by Anderson & Anderson 1971:30 (References in Wood & Bright c1992:399)

Scolytodes boliviensis Wood, 1988:32. Lectotype ♂; Cochabamba, Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:7, replacement name, automatic (Synonymy and references in Wood & Bright c1992:389). *New synonymy*

Prionosceles bolivianus Eggers, 1928:88. Lectotype ♂; Cochabamba, Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:7, preoccupied by Eggers 1928:86. *New synonymy*

Diagnosis: Distinguished from *opaca* Wood by the confused elytral punctures from base to apex, without any tubercles on the disc; and by other characters cited below.

Male: Distinguished from female by abdominal terga 7 and 8.

Female: Length 2.4–2.8 mm, about 2.2 times as long as wide; color very dark reddish brown. Frons moderately convex from epistoma to vertex, weakly impressed near central fovea; surface reticulate from epistoma to upper level of eyes, much more strongly reticulate (almost rugose reticulate) above eyes; punctures small, rather close below fovea, larger and more widely spaced above to well above upper level of eyes; subglabrous, a few short setae on lower half, longer and more conspicuous on and near epistoma. Pronotum 1.0 times as long as wide; dorsal profile rather evenly arched from base, slightly steeper on anterior slope, anterior half very finely, closely asperate, asperities isolated; posterior half reticulate, punctures fine, close, deep; vestiture of very fine, rather abundant, moderately long hair. Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; striae 1 and 2 obsolete, 3 very obscure, numerous small interstitial punctures strongly confused from base to apex. Declivity broadly convex, gradual, weakly impressed between interstriae 3, position of striae 1 more strongly impressed (strial punctures obsolete); punctures minute, confused; surface smooth, shining. Vestiture of rather short, abundant, recumbent hair from base to apex.

Distribution: Panama to Bolivia.

Panama: Guadeloupe arriba Chiriqui, 1-VIII-4-IX-1984, H. Wolda.

Bolivia: Cochabamba [F. Woytkowski].

Biology: Attracted to light.

Notes: The above treatment was based on the female lectotype of *Prionosceles similis* Eggers, on the male holotype of *Prionosceles bolivianus* Eggers (1928:88), and on 1 female from Panama. The lectotype of *similis* was compared directly to my Panama specimen, and the Panama specimen I compared directly to the holotype of *bolivianus* Eggers.

Scolytodes maja (Eggers)

Scolytodes major (Eggers), 1928:86 (*Prionosceles*). Holotype ♂?; Bolivia; USNM, Washington (References in Wood & Bright c1992:394)

Diagnosis: Distinguished from *similis* (Eggers) by the larger size; by the more gradual elytral declivity, with declivital punctures much smaller; and by the presence of a weak, median impression of the frons.

Male (?): Length 4.0 mm, 2.1 times as long as wide; color almost black. Frons very broadly convex, surface rugose-reticulate above middle, almost smooth and shining in some areas below; a weak median sulcus on middle third, ending just above level of antennal insertion in an obscure fovea; lateral areas with a few small, subcrenulate tubercles; vestiture of sparse, fine, rather short hair. Pronotum 1.0 times as long as wide; anterior margin rather narrowly rounded, unarmed; summit indefinite, well behind middle; surface reticulate on posterior half, fading to obscurity on anterior areas, asperities rather small, isolated, reduced to small subcrenulate granules at summit; posterior third closely, deeply, finely punctured; vestiture of fine, short, moderately abundant hair.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; striae not indicated, punctures on basal half of disc rather small, deep, confused, becoming very minute behind and on declivity, each puncture about equal in diameter to thickness of an adjacent seta, sparse on declivity; surface smooth, shining; vestiture of fine, rather short, moderately abundant hair.

Distribution: Bolivia: "Bolivia, collected 1948."

Notes: The above treatment was based on the holotype from Bolivia, presumably a male.

Species Not Seen

Scolytodes columbiana (Schedl)

Scolytodes columbianus (Schedl), 1967:160 (*Hexacolus*). Holotype ♂; Sierra S. Lorenzo, Colombia; NHMB, Budapest (References in Wood & Bright c1992:390). Not at Budapest Museum

Scolytodes interpunctata (Eggers)

Scolytodes interpunctatus (Eggers), 1943:366 (*Prionosceles*). Holotype, sex?; Cochabamba, Bolivia; MNHN, Paris (References in Wood & Bright c1992:393)

Scolytodes laevicorpa Wood

Scolytodes laevicorpus Wood, 1988:33. Holotype, sex?; Cochabamba, Bolivia; MNHN, Paris, automatic (References in Wood & Bright c1992:394)

Hylocurosoma laevae Eggers, 1943:367. Holotype, sex?; Cochabamba, Bolivia; MNHN, Paris, preoccupied by 1928:88 (References in Wood & Bright c1992:394)

Scolytodes laevis (Eggers) *laevae*

Scolytodes laevis (Eggers), 1928:88 (*Prionosceles*). Holotype, sex?; E Bolivia; NHMW, Wien (References in Wood & Bright 1992:394)

TRIBE MICRACINI

Description: Frons usually dimorphic, either sex may be variously impressed, sculptured, or ornamented by setae, female frons often concave, male frons rarely concave; eye oval to elongate, entire to sinuate on anterior margin; scape very short to elongate, slender to strongly flattened or expanded, often ornamented by setae; funicle 6-segmented, club with or without sutures. Pronotum asperate on anterior area, lateral margins rounded; protibia usually with sides parallel, socketed denticles usually confined to apical margin; procoxae distinctly separated. Subplumose setae almost always present somewhere on body.

Biology: All genera are bigynous except for the monogynous *Micracisella*. *Pseudothymanoes* are mostly phloeophagous; a few are xylophagous. All *Hylocurus* and *Micracis* are xylophagous. *Micracisella* are myelophagous in small stems. Details of the life cycle are very poorly known. The larvae bore independent mines that often are unusually long and tortuous. Members of this tribe occur in South America, southern North America, South Africa, and 1 species occurs in Asia (northern China).

Key to the Genera of Micracini

(Adapted from Wood 1986:62–63)

1. Elytra broadly rounded behind; protibia much more slender, less strongly flattened; lateral margins of antennal club constricted at procurved sutures (except almost obsolete in all known South American *Pseudothymanoes*) ***Pseudothymanoes***
- Elytral apices acuminate to mucronate (partly lost in some *Micracisella*); protibia more strongly flattened, at least apically; antennal club without constrictions at sutures, sutures always indicated on anterior face 2
- 2(1). Eye short, oval, not more than 1.5 times as long as wide, finely faceted; sutures on antennal club straight to strongly procurved; posterior face of protibia tuberculate; protibia rather slender, wider apically ***Hylocurus***
- Eye elongate, 2.0 or more times as long as wide, coarsely faceted; antennal club rather large, sutures strongly procurved; protibia strongly flattened, sides usually parallel, its posterior face not tuberculate 3
- 3(2). Eye shallowly emarginate, often approximate below; protibia less strongly flattened, at least 1 of 5 apical teeth on outer (lateral) margin; scape usually less strongly expanded; antennal club rather broad, sutures more broadly procurved; monogynous, myelophagous ***Micracisella***
- Eye entire, always widely separated below; protibia more strongly flattened, all 5 teeth on apical margin; scape usually very strongly expanded (especially in female); antennal club more elongate, sutures usually much more strongly, narrowly arcuate; bigynous, xylophagous ***Micracis***

GENUS *PSEUDOTHYSANOES* BLACKMAN

Pseudothymanoes Blackman, 1920:46. Type-species: *Pseudothymanoes drakei* Blackman = *Cryphalus rigidus* LeConte, original designation (Synonymy and references in Wood & Bright c1992:411)

Cryptocleptes Blackman, 1920:51. Type-species: *Cryptocleptes dislocatus* Blackman, original designation, preoccupied by Simon 1884

Chalcohyus Blackman, 1943:363. Type-species: *Chalcohyus securigerus* Blackman, original designation

Bostrichips Schedl, 1951:21. Type-species: *Bostrichips spinatus* Schedl, monobasic

Gretschkinia Sokanovskii, 1959:276. Type-species: *Gretschkinia mongolica* Sokanovskii, monobasic

Aphanocleptus Wood, 1960:63. Type-species: *Aphanocleptus coniferae* Wood, original designation

Cryptulocleptus Wood, 1962:76. Type-species: *Cryptocleptes dislocatus* Blackman, automatic

Neoglostatus Schedl, 1978:300. Type-species: *Neoglostatus squamosus* Schedl, monobasic

Diagnosis: Allied to the North American *Thysanoes*; elytral apex broadly rounded (not mucronate); antennal club constricted at suture 1 and sometimes at 2, sutures straight, procurved, or obsolete; protibia more slender,

less distinctly flattened; most species phloeophagous (xylophagous in a few North American species).

Description: Small species (0.7–1.4 mm), stout to rather slender (2.0–2.8 times as long as wide), males often smaller than females; frons usually dimorphic, varying from convex to rather deeply concave in either sex; antennal scape very short to elongate, with or without a tuft of setae, club small to very large, with sutures straight to procurved to obsolete (all South American species). Pronotum often wider than long; asperities rather

coarse. Elytra usually sexually dimorphic in sculpture and/or vestiture.

Distribution: Wood & Bright (c1992:411–419) list 89 species, 12 of which have been reported from South America. The species are small and breed in small stems, where they are of minor economic importance.

Biology: Most species are phloeophagous; about 6 North American species are xylophagous, a habit not yet known from South America.

Key to the Species of *Pseudothysanoes*

- 1. Posterior margin of visible abdominal sternum 5 rather broadly rounded, without a median, spine-like process (or short carina) at apex in either sex; male interstriae on disc near base of declivity each usually armed by several rounded nodules 2
- Posterior margin of visible abdominal sternum 5 narrow, in female forming a small spine, male with a slightly wider (somewhat carinate) process; male interstriae on disc near declivity not armed by nodules 6
- 2(1). Body stout, 2.2–2.3 times as long as wide, very small; 1 or both sutures obsolete on antennal club 3
- Body very slender, 2.7 or more times as long as wide; rudiments of sutures present on antennal club 4
- 3(2). Male declivity very broadly rounded, none of interstriae at or near its base armed by pointed denticles, interstitial nodules restricted to posterior one-fourth of disc, smaller but indicated on upper declivity; female similar to male except all declivital setae hairlike, scales not present as in male; frons strongly convex, scape without a tuft of hair; Venezuela; *Theobroma cacao*; 0.7–0.9 mm *atomus* Wood
- Male declivity less broadly convex, interstriae 2, 3, 6, 7, and 8 each armed at base of declivity by a small, sharply pointed denticle, nodules small, less clearly evident on disc and declivity; similar to male except denticles absent, frons rather shallowly concave, scape with a conspicuous tuft of hair; Brazil (Santa Catarina); 1.2–1.4 mm *bellus* (Schedl)
- 4(3). Elytral declivity flattened to distinctly concave on lower half; declivital interstriae 3 armed near middle of declivity length by a small spine; Chile; 1.7–2.0 mm *spinatus* (Schedl)
- Elytral declivity strongly convex from base to apex, without spines 5
- 5(4). Posterolateral areas of pronotum mostly smooth, shining; striae punctures on declivity as large and as deep as on disc; erect interstitial scales on declivity each almost three to four times as long as wide; female frons very shallowly, narrowly impressed; body not as slender; Argentina; 1.5–1.6 mm *argentiniae* (Schedl)
- Posterolateral areas of pronotum rugose-reticulate, dull; striae punctures on declivity reduced in size and depth to less than half size of those on disc; erect interstitial scales on declivity stouter, each about two to three times as long as wide; female frons more strongly, more broadly impressed; body more slender; Chile; 1.7–1.8 mm *guevinae* (Schedl)
- 6(1). Smaller species (1.0–1.1 mm); female frons convex (concave in *murilloi*?), scape simple (club-shaped), either without setae or with a very large tuft of setae (female of *murilloi*?) 7
- Larger species (1.1–1.3 mm); female frons partly to extensively concave, scape variable, with a moderate to large tuft of hair 9

- 7(6). Declivity very steep, very broadly convex, interstitial scales densely placed, those on basal half of 1 and 2 moderately confused; male body stouter, 2.2 times as long as wide; Colombia; 1.0 mm
 *colombianus* (Blackman)
- Declivity rather gradual, narrowly convex, interstitial scales always uniseriate, not as close 8
- 8(7). Male frons more uniformly, more strongly convex; elytral declivity more broadly convex, striae 1 and 2 with punctures distinctly impressed, more obscure on 3; Brazil (Mato Grosso); 1.1 mm . . .
 *unimodus* (Schedl)
- Male frons much less strongly convex, somewhat flattened laterally; elytral declivity more narrowly convex, punctures on striae 2 and 3 distinct, obscure on 1; Colombia; 1.1 mm
 *murilloi* (Blackman)
- 9(6). Female frons strongly sulcate on median one-fourth from near epistoma to upper level of eyes, concave area smooth, shining, glabrous, scape slender, club-shaped, with rather numerous, long setae uniformly distributed; female interstitial setae three to four times as long as wide, male setae almost as wide as long; Brazil (Santa Catarina); 1.2–1.3 mm *plaumanni* (Schedl)
- Female frons concave eye to eye from epistoma to upper level of eyes 10a
- 10a(9). Female frons very strongly concave from epistoma to vertex, upper margin strongly, subacutely elevated to narrowly rounded, concave area reticulate, impunctate, glabrous; female declivity strongly convex, unarmed by tubercles or spines; male declivity somewhat truncate, with a circumdeclivital ring of small, sharply pointed spines from suture above to interstriae 8, ventrolateral margin costate from suture apex to interstriae 9; Brazil (MS); *Anadenanthera peregrina*; 1.3–1.5 mm *multispinosus* Wood
- Female frons less deeply concave from epistoma to vertex, upper margin rounded, much less strongly elevated, concave area with at least a few setae and/or minute punctures; male declivity convex, not at all subtruncate, unarmed 10b
- 10b(10a). Female frons rather strongly concave from epistoma to well above upper level of eyes, surface smooth, brightly shining, punctures minute, very sparse; female scape slender, club-shaped, without a tuft of hair; female interstitial setae shorter, each equal in length to about half distance between rows, each about three to four times as long as wide; Brazil (Parana); 1.1–1.2 mm
 *dimorphus* (Schedl)
- Female frons rather strongly concave from epistoma to well above upper level of eyes, surface subshining, densely covered by fine punctures; female scape greatly expanded, area beyond flagellum insertion as large as remainder of scape, ornamented by a large, conspicuous tuft of long hair; Brazil (Parana to Santa Catarina); 1.2–1.3 mm *abbreviatus* (Schedl)

Pseudothysanoes atomus Wood

Pseudothysanoes atomus Wood, 1980:355. Holotype: ♂; Finca Monasterios, Caucauga, Miranda, Venezuela; USNM, Washington (References in Wood & Bright c1992:412)

Diagnosis: Posterior margin of visible abdominal sternum 5 broadly rounded (not at all mucronate in either sex); male interstriae near base of declivity each armed by several rounded nodules; male declivity broadly rounded, without any pointed denticles near its base.

Male: Length 0.7–0.9 mm, 2.24 times as long as wide; color yellowish to reddish brown. Frons convex, shining below, reticulate above, somewhat irregularly, rather closely punctured; vestiture rather short, sparse, inconspicuous. Pronotum 1.0 times as long as wide; anterior

half declivous, rather closely asperate, most asperities isolated, confused, anterior margin armed by two closely set denticles at median line; posterior half shining, subreticulate, with small, isolated granules behind summit to base, posterolateral areas with sparse, minute punctures; vestiture of moderately abundant, short hair, about uniformly distributed. Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures small, shallow anteriorly, some spaces between striae punctures slightly to strongly enlarged into rounded nodules; interstriae as wide as striae, smooth, shining, impunctate, near base of declivity of most interstriae with two or three rounded nodules similar to those of striae. Declivity very steep, broadly convex; most striae indicated by a few punctures interspersed with small,

rounded granules, interstriae 1, 3, and lateral areas with similar rounded granules. Vestiture near and on declivity, consisting of short erect interstitial hair; and on base of declivity and interstriae 1, 4, and lateral areas with a few erect, rather broad scales, all setae equal in length to about two-thirds distance between rows.

Female: Body 2.5 times as long as wide; similar to male except anterior margin of pronotum unarmed; elytra with strial and interstitial nodules similar but smaller; declivity more distinctly convex, all setae hairlike, no scales present.

Distribution: Venezuela: Finca Monasterios, Cacagua, Miranda, 1971, *Theobroma cacao*, J.L. Saunders.

Biology: Boring in phloem of twigs.

Notes: The above treatment was based on the type series of 13 specimens.

Pseudothysanoes bellus (Schedl)

Pseudothysanoes bellus (Schedl), 1954:28 (*Cryptocleptes*). Lectotype ♂; Rondon, Parana, Brazil, 500 m; NHMW, Wien, designated by Schedl 1979:36 (References in Wood & Bright c1992:412)

Diagnosis: Distinguished from *atomus* Wood by the less strongly convex declivity, armed at base by small, pointed denticles on interstriae 2, 3, 6, 7, and 8; by the male frons being shallowly concave, scape with a tuft of hair.

Male: Length 1.2–1.4 mm, 2.3 times as long as wide; color very dark brown, vestiture pale. Frons convex above, lower half transversely somewhat flattened, a small epistomal callus on median one-fourth; surface reticulate-granulate, upper areas with small, sparse granules; vestiture sparse, short, inconspicuous, longer, more abundant along epistoma; antennal scape with about 8–10 moderately long setae, club oval, smooth, shining, sutures obsolete, lateral and apical margins with a rather dense fringe of short hair. Pronotum 0.9 times as long as wide; summit at middle, distinct; anterior slope rather coarsely, closely asperate, some obscurely subconcentric; posterior and lateral areas rugose-reticulate, with sparse, fine, irregularly shaped granules; vestiture moderately abundant, a mixture of short hair and suberect scales in both asperate and posterior areas, each scale about two to three times as long as wide. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures rather coarse, moderately deep; interstriae as wide as striae, shining, punctures about one-third as wide as those of striae, uniseriate, their anterior margin weakly elevated, rather strongly elevated and tuberculate near base of declivity. Declivity very steep, very broadly convex; interstriae 2, 3, 6, 7, and 8 each armed by a small denticle at base, strial punctures on 1 and 2 mostly uniseriate, lateral punctures confused. Vestiture of short strial hair and erect, uniseriate interstitial scales from base to apex, each slightly longer than wide, those at base of declivity slightly larger, those on declivity smaller.

Female: Body 2.6 times as long as wide; similar to male except frons subconcavely impressed to upper level

of eyes; strial and interstitial punctures smaller, without interstitial tubercles, declivity more strongly convex, without denticles at base; declivital strial punctures in recognizable rows, declivital interstriae each with 1 uniseriate row of small tubercles, scales similar on disc and declivity.

Distribution: Brazil: Rondon, Parana, 24°38'B, 54°07'L, 1951, 500 m, F. Plaumann.

Notes: The above treatment was based on 13 specimens from Brazil, 1 of which was compared by me to the male lectotype.

Pseudothysanoes spinatus (Schedl)

Pseudothysanoes spinatus (Schedl), 1951:21 (*Bostrichips*). Lectotype ♂; Chile; NHMW, Wien, present designation (References in Wood & Bright c1992:417)

Diagnosis: Distinguished from all other species in this genus by the distinctive elytral declivity, described below; and by other features described here.

Male: Length 1.7–2.0 mm, 2.97–3.0 times as long as wide; color very dark brown, summit of pronotum reddish brown. Frons strongly convex above upper level of eyes, lower half rather abruptly, strongly impressed on lower half; lower fourth almost flat from margin to margin, lower fourth almost smooth, obscure punctures sparse, minute; closely, somewhat rugosely punctured on upper half. Antennal scape almost as long as club, triangularly flattened (as wide as long), ornamented by a small tuft of hair; club longer than wide, 2 sutures weakly recurved. Pronotum 1.04 times as long as wide; summit slightly anterior to middle of pronotum length; anterior slope rather coarsely asperate on median half, anterior margin unarmed (1 denticle on type, none on other male); posterior half smooth, shining, punctures rather coarse, deep, very close; vestiture of short, stout bristles in asperate area, sparse, fine behind. Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; disc occupying basal two-thirds of elytra length; striae not impressed, punctures deep, rather small, smaller on basal fourth; interstriae as wide as striae, almost smooth, shining, punctures uniseriate, smooth to obsolete. Declivity very steep, shallowly, broadly sulcate; strial punctures on 1 and 3 confused; interstriae 3 armed slightly above middle by a moderately coarse, pointed spine; lateral margin on lower fourth moderately elevated, its dorsal end forming a small spine. Vestiture mostly abraded, apparently consisting of interstitial rows of stout, erect setae, each seta about as long as distance between rows.

Distribution: Chile: "Chile, Fairm.," male; "Holotype, *Bostrichips spinatus*"; "Chile, leg. Kuschel"; "Chili, F. Sohlb.," *Bostrichips spinatus* n. sp., type Eggers det., female; (?) Julir. Coll'd. Chev. Chili, L. Guillolot (apparently, very difficult to read and interpret).

Notes: Of the 5 specimens in the Schedl material at NHMW, Wien, are "2 males" and "2 females," and 1 with sex not indicated. The first "male" was labeled type (and subsequently) "holotype," the fourth, "female" as "type."

This species was named from a syntypic series of males and females. Subsequently, Schedl (1979:234) designated the first male as the "holotype," contrary to the International Code on Zoological Nomenclature. I here designate that specimen as the male lectotype of *Bostrichips spinatus* Schedl. All 5 specimens appear to be female.

Pseudothysanoes argentinae (Schedl)

Pseudothysanoes argentinae (Schedl), 1958:43 (*Bostrichips*). Lectotype ♀; Cordoba, Dep. Pumilla, Argentina; NHMW, Wien, designated by Schedl 1979:25 (References in Wood & Bright c1992:412)

Diagnosis: Distinguished from *spinatus* (Schedl) by the weakly elevated declivital interstriae 1 and 3, interstriae 3 with a row of about 4 minute tubercles, major spines absent, ventrolateral margin rather weakly elevated; striae punctures on disc much smaller than on *spinatus*, etc.

Female: Length 1.5 mm, 2.8 times as long as wide; color very dark brown. Frons mostly convex, weakly, shallowly impressed on median half of upper half; sculpture apparently rather finely punctate-rugose in lateral and upper areas, finer toward center (not clearly visible from angle available); vestiture short, sparse. Both antennae missing from type. Pronotum 0.96 times as long as wide; about as in *spinatus* except posterolateral areas weakly subrugose-reticulate, punctures much smaller, more widely separated; anterior submargin armed by an irregular row of 6 serrations; vestiture in asperate area more nearly scalelike, on posterior half of sparse, short scales, each scale about twice as long as wide. Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; disc occupying basal 80 percent of elytral length; striae not impressed, punctures small, shallow; interstriae twice as wide as striae, irregular punctures largely replaced by small tubercles on their anterior margin. Declivity steep, convex; interstriae 1 and 2 weakly elevated and finely serrate, a weak, transverse, subapical elevation extending from 1 to 7. Vestiture of erect interstitial scales, each scale two to three times as long as wide and about as long as distance between rows; most setae on declivity absent (due to abrasion?).

Distribution: Argentina: Cordoba, Dep. Punilla, Villa Hermosa, H.J. Viana, type, *Bostrichips argentinae* Schedl.

Notes: This species was based on a syntypic series. Schedl (1979:25) designated the first specimen in his series as the lectotype for this species. The second specimen is of a different species. The above treatment was based on the male lectotype.

Pseudothysanoes guevinae (Schedl)

Pseudothysanoes guevinae (Schedl), 1966:45 (*Bostrichips*). Holotype ♀; Termas, S Chile; Manzanar; NHMW, Wien (References in Wood & Bright c1992:414)

Diagnosis: Distinguished from other South American members of this genus by the slender body form; by the

strongly reticulate pronotum; and by the evenly convex elytral declivity.

Male: Similar to female except frons strongly convex above eyes, strongly impressed (feebly concave) below; interstitial setae on declivity mostly twice as long as wide and continued to apex.

Female: Length 1.7–1.8 mm, 3.3 times as long as wide; color dark brown, vestiture pale. Frons broadly convex (transversely) to above upper level of eyes, feebly convex to straight longitudinally; median half smooth, brightly shining from epistomal margin to above eyes; lateral areas minutely punctate-granulate and ornamented by sparse, modestly long hair. Antennal scape ornamented by rather numerous long setae; club slightly longer than wide, two sutures rather strongly procurved. Pronotum 1.1 times as long as wide; summit slightly in front of middle of pronotum length, anterior slope rather coarsely asperate, anterior margin armed by four median serrations; surface strongly reticulate from anterior to posterior margin, a few scattered granules on disc, punctures sparse, minute, obscure; vestiture of sparse, short, fine hair. Elytra 2.1 times as long as wide, 1.9 times as long as pronotum; striae not impressed, punctures rather small, shallow; interstriae slightly wider than striae, almost smooth, punctures very small, obscure, uniseriate. Declivity steep, strongly convex; striae 1–3 obscure; interstriae 1–3 equally, weakly convex, each with a row of punctures distinctly larger than on disc. Vestiture of rows of erect interstitial setae, those on disc hairlike to very slender, becoming scalelike near base of declivity (each seta four to six times as long as wide, length equal to two-thirds distance between rows), small to obsolete on lower half of declivity.

Distribution: Chile: Sudchile, Termas Manzanar, 5-X-1963, *Guevina avallana*, W. Ruehm (type).

Notes: The above treatment was based on the female holotype, 2 males, and 3 other females, all bearing identical data.

Pseudothysanoes colombianus (Blackman)

Pseudothysanoes colombianus Blackman, 1943:361 (*Cryptocleptes*). Holotype ♂; San Vicente, Santander, Colombia; USNM, Washington (References in Wood & Bright c1992:412).

Diagnosis: Posterior margin of visible sternum 5 very narrowly rounded to submucronate; female frons convex, scape slender, without a tuft of long hair; declivity very steep, interstitial scales closely placed.

Male: Length 1.0 mm, 2.3 times as long as wide; color very dark brown, vestiture pale. Frons apparently convex on upper half (concealed on my specimen), lower area somewhat flattened, lateral thirds very finely, rather closely punctured, median third smooth, shining, almost impunctate; scape slender, without a tuft of hair; club with one weakly procurved suture near middle indicated by a row of hair, several setae on margins. Pronotum 0.88 times as long as wide; summit definite, anterior slope coarsely, closely asperate, anterior margin armed by six low serrations; posterior areas rugose-

reticulate, minute punctures obscure; vestiture moderately abundant, stout, rather short, suberect. Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae not impressed except near declivity, punctures small, distinctly impressed; interstriae about twice as wide as striae, punctures not clearly evident, 1 and 2 finely subcrenulate to base, others only near declivity. Declivity very steep, broadly convex; striae feebly impressed, punctures irregularly impressed, obscure on 1. Vestiture of short, stout, interstitial scales, each very slightly longer than wide, those on declivital interstriae 1 and 2 slightly confused near base, others uniseriate.

Distribution: Colombia: Dep. Santander, 29-VII-1935, 700-1300 m, *Inga laurina*, R.P. Roba; Vincente, Santander, VI-1935, 692 m, Calopo, L.M. Murillo.

Notes: The above treatment was based on 1 male that was compared by me to the male holotype. The holotype has the declivital scales on interstriae 1 and 2 uniseriate, not confused.

Pseudothysanoes unimodus (Schedl)

Pseudothysanoes unimodus (Schedl), 1959:549 (*Cryptocleptes*). Holotype ♂; Rio Caraguata, Mato Grosso, Brazil; NHMW, Wien (References in Wood & Bright c1992:418)

Diagnosis: Distinguished from *murilloi* (Blackman) by the less strongly convex male frons, punctures on striae 1 distinctly impressed.

Male: Length 1.1 mm, 2.4 times as long as wide; color very dark reddish brown. Frons rather strongly convex; rugose-reticulate on more than upper half, apparently more finely sculptured below; vestiture of sparse, fine hair; scape elongate, without a tuft of hair. Pronotum 0.90 times as long as wide; summit distinctly elevated, anterior slope rather coarsely asperate, anterior margin armed by one small lateral and four moderately large serrations; lateral areas behind mostly smooth, shining, partly, weakly rugose-reticulate to disc; vestiture sparse, semirecumbent, moderately coarse, rather short hair. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures small, distinctly impressed; interstriae slightly wider than striae, almost smooth, small, uniseriate punctures weakly granulate. Declivity rather narrowly convex, steep; striae punctures slightly larger and deeper than on disc, interstitial punctures much closer within a row. Vestiture of minute striae hair (at least on declivity), interstitial scales erect, uniseriate, each up to three times as long as wide on disc, only slightly longer than wide on declivity, scales much more closely spaced on declivity than on disc.

Female: Similar to male except scape ornamented by a dozen or more moderately long setae uniformly distributed; anterior margin of pronotum armed by 4 serrations; elytra 1.7 times as long as wide; striae and interstitial punctures much smaller; granules absent; interstitial scales on disc about six times as long as wide, four times as long as wide on declivity.

Distribution: Brazil: Rio Caraguata, Mato Grosso, III-1953, F. Plaumann.

Notes: The above treatment was based on 1 male paratype and 1 female paratype that were received through exchange from Schedl.

Pseudothysanoes murilloi (Blackman)

Pseudothysanoes murilloi (Blackman), 1943:360 (*Cryptocleptes*). Holotype ♀; San Vicente, Sant., Colombia, 692 m; USNM, Washington (References in Wood & Bright c1992:415)

Diagnosis: Distinguished from *unimodus* (Schedl) by the less strongly convex male frons; and by the more narrowly convex elytral declivity, with punctures on striae 1 obscure.

Male: Length 1.1 mm, 2.7 times as long as wide; color very dark reddish brown, vestiture pale. Similar to *unimodus* except lower frons more nearly flattened over a larger area; posterior area of pronotum more nearly smooth; elytra 1.7 times as long as wide, declivity more narrowly convex, declivital striae more weakly impressed, punctures smaller, somewhat obscure on 1.

Female: Length 1.19 mm, 2.9 times as long as wide; frons broadly concave, a small fovea at center; scape flattened, wider distally, fringed with long hair; anterior margin of pronotum unarmed by serrations; elytra 1.9 times as long as wide, striae punctures small, in rows (after Blackman 1943:360–361, not seen).

Distribution: Colombia: San Vicente, Santander, VI-1935, 692 m, No. 159, Calapo, L.M. Murillo.

Hosts: *Albizzia macrocarpa*.

Biology: In a branch of the host.

Notes: The above treatment was based on a male paratype.

Pseudothysanoes plaumanni (Schedl)

Pseudothysanoes plaumanni (Schedl), 1951:106 (*Cryptocleptes*). Syn-types, sex?; Nova Teutoni, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:416)

Diagnosis: Female frons concavely sulcate on median one-fourth, concave area smooth, glabrous.

Male: Length 1.2-1.3 mm, 2.3 times as long as wide; color very dark reddish brown, vestiture pale. Frons strongly convex, a weak impression at median line on middle half; vestiture of sparse, short hair on lower half. Pronotum 0.80 times as long as wide; summit distinctly elevated, anterior slope coarsely asperate, anterior margin armed by 8 coarse serrations; vestiture sparse, of short, coarse hair. Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; striae 1 weakly, others not impressed, punctures rather small; interstriae about as wide as striae, almost smooth, punctures smaller than those of striae, those near suture granulate. Declivity broadly convex, steep; striae more distinctly impressed, punctures slightly larger, deeper; tubercles on 1 and 2 distinct, obscure elsewhere. Vestiture of minute, fine striae hair (at least on declivity) and erect interstitial scales in uniseriate rows, each scale on disc about three times as long as wide, less than twice as long as wide on

declivity (declivital rows 2 and 3 usually very slightly confused).

Female: Frons concave on median one-third from near epistoma to upper level of eyes, concavity smooth, brightly shining; scape club-shaped, ornamented by about 20 long, uniformly distributed setae; serrations on anterior margin of pronotum obscure to obsolete; elytra 1.6 times as long as wide; striae on disc not impressed, punctures small to minute, interstriae shining, transversely wrinkled, granules absent, punctures minute, uniseriate; interstitial scales on disc about six times as long as wide, on declivity about four times as long as wide.

Distribution: Brazil: Nova Teutonia, Santa Catarina, XI-1956, 300–500 m, 27°11B, 52°23L, F. Plaumann.

Notes: The above treatment was based on 12 specimens from Brazil; 1 male was compared to the male holotype, and 1 female was compared by me to the female allotype.

Pseudothysanoes multispinosus, n. sp.

Pseudothysanoes multispinosus Wood: Holotype ♂; UNESP Farm, Selviria, Mato Grosso do Sul, Brazil; MZUSP, Sao Paulo, designated below

Diagnosis: Distinguished from *abbreviatus* (Schedl) by the slightly larger size; by the more strongly concave female frons, with upper margin subacutely elevated, and with the concave area reticulate and glabrous; by the strongly convex female declivity that lacks tubercles or spines and male that has a circumdeclivital ring of small sharply pointed spines.

Male: Length 1.2–1.3 (female 1.4–1.5) mm, 2.0 (female 2.2) times as long as wide. Frons broadly convex, surface rugose-reticulate, epistomal brush with many setae; antennal club small, oval, margins of suture 1 marked by a row of setae. Pronotum 0.76 times as long as wide; widest near middle of pronotum length, sides strongly arcuate on basal half, broadly rounded in front; anterior margin armed by four serrations on median area; summit well behind middle of pronotum length; anterior slope on median half armed by coarse asperities forming obscure concentric rows on and near summit; posterior areas reticulate, punctures very small, moderately numerous; vestiture of numerous scales, each slightly longer than wide, and on basal and lateral areas scales intermixed with very short, slender setae. Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; disc occupying 80 percent of elytra length; striae not impressed, punctures large, strongly impressed, close; interstriae half as wide as striae, punctures uniseriate, almost as wide as interstriae. Declivity very steep, moderately, broadly convex; discal apex of interstriae 1–8 armed by a sharply pointed spine (very small on 1); ventrolateral margin subacutely costate from suture to about level of interstriae 3, then continued by a row of tubercles to junction with interstriae 8; interstriae 1 and 2 on face of declivity each with a dense row of closely set broad

scales (each about as long as wide on lower two-thirds of declivity length); interstriae 3 near base (below spine on circumdeclivital row) with one rather large, sharply pointed spine; area laterad from striae 2 with large, confused punctures; short slender setae mostly abraded. Vestiture of interstitial rows of broad scales on disc and on interstriae 1 and 2 on declivity.

Female: Body 2.2 times as long as wide. Frons strongly, transversely impressed from epistoma to vertex; surface rugose-reticulate; many small setae on impressed area above upper level of eyes, epistomal brush with many setae. Pronotum similar to male, except serrations absent on anterior margin. Elytral disc with striae punctures smaller, interstriae slightly wider than striae; declivity without spines; punctures on lateral areas similar to disc, rows of interstitial scales continue to end of interstriae.

Distribution: Brazil (Mato Grosso do Sul).

Type material: The male holotype, female allotype, and 6 male and 5 female paratypes were taken at the UNESP Farm, Selviria, Mato Grosso do Sul, Brazil, 2-VIII-1998, *Anadenanthera peregrina* branch, C.A.H. Flechtmann. The holotype, allotype, and 9 paratypes are in the Museu de Zoologia, Universidade de Sao Paulo, Sao Paulo. Two paratypes are in the U.S. National Museum, Washington.

Pseudothysanoes dimorphus (Schedl)

Pseudothysanoes dimorphus (Schedl), 1954:25 (*Cryptocleptes*). Lectotype ♂; Rondon, Parana, Brazil, 500 m; NHMW, Wien, designated by Schedl 1979:81 (References in Wood & Bright c1992:413)

Diagnosis: Distinguished from *plaumanni* (Schedl) by the broadly concave, smooth, shining female frons from epistoma to vertex.

Male: Length 1.1–1.2 mm, 2.1 times as long as wide; color dark reddish brown. Frons strongly, broadly convex; rugose-reticulate on its dorsal two-thirds, becoming reticulate below; vestiture of sparse, fine, inconspicuous hair; scape small, flattened, with a small tuft of long hair. Pronotum 0.82 times as long as wide; summit distinctly elevated, anterior slope coarsely asperate (asperities near summit subconcentric), anterior margin armed by 6 serrations; surface behind summit rugose-reticulate, becoming reticulate toward lateral areas; vestiture of two kinds, slender, short hair over most of surface, in asperate area with scales intermixed, scales varying from 2–6 times as long as wide. Elytra 1.3 times as long as wide; striae weakly impressed, punctures small, deep; interstriae slightly wider than striae, smooth, shining, small rounded, uniseriate, setiferous granules closely set from base to elytral apex. Declivity broadly convex, steep; sculpture about as on disc. Vestiture of rows of recumbent striae hair and erect, uniseriate rows of interstitial scales, each scale one to two times as long as wide (spaced within a row by length of a scale), scales on declivity slightly smaller.

Female: Similar to male except frons transversely impressed to shallowly concave eye to eye from epistoma

to upper level of eyes, vestiture more abundant, longer above; scape strongly flattened and extended beyond insertion of flagellum; anterior margin of pronotum unarmed; elytra 1.4 times as long as wide, striae not impressed, punctures much smaller; interstitial tubercles greatly reduced to obsolete, interstitial scales up to six times as long as wide on disc, about four times as long as wide on declivity.

Distribution: Brazil: Rio Caraguata, Mato Grosso, III-1953, F. Plaumann; Rondon, Parana, 24°38'B, 54°07'L, IV-1960s, 500 m, F. Plaumann.

Notes: The above treatment was based on 2 male paratypes and 2 female paratypes from Brazil.

Pseudothysanoes abbreviatus (Schedl)

Pseudothysanoes abbreviatus (Schedl), 1954:26 (*Cryptocleptes*).
Lectotype ♂; Rondon, Parana, Brazil, 500 m; NHMW, Wien, designated by Schedl 1979:8 (References in Wood & Bright c1992:411)

Neoglostatus squamosus Schedl, 1978:300. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:417). *New synonymy*

Diagnosis: Distinguished from *dimorphus* (Schedl) by the minutely, closely punctured female frons; and by the strongly expanded female scape that is ornamented by a large tuft of hair.

Male: Length 1.2–1.3 mm, 2.2 times as long as wide; color almost black, vestiture pale. Frons rather weakly convex, central one-fifth weakly impressed, surface reticulate; scape slender, without long setae. Pronotum similar to *dimorphus* except anterior margin armed by four serrations, vestiture mostly abraded, apparently similar. Elytra 1.4 times as long as wide; similar to *dimorphus* except discal interstriae obscurely tuberculate (tubercles minute to irregularly obsolete) on disc and declivity. Interstitial scales shorter, always uniseriate, those on disc up to twice as long as wide, those on declivity very short, some half as long as wide.

Female: Body 2.7 times as long as wide; frons rather strongly concave from epistoma to vertex, surface smooth, shining, glabrous, sparse, very minute punctures present; scape slender, a small tuft of long hair present; serrations on anterior margin of pronotum almost obsolete;

striae not impressed, punctures minute, interstriae finely wrinkled, punctures minute, obscure, erect scales at base of disc about six times as long as wide, those on declivity about three times as long as wide.

Distribution: Brazil: Rondon, Parana, 24°38'B, 54°07'L, 1969s, 600 m, F. Plaumann.

Notes: The above treatment was based on 1 male paratype and 1 female paratype of *abbreviatus*, on the male holotype of *Neoglostatus squamosus*, and on 37 other specimens, all from Brazil.

GENUS *HYLOCURUS* EICHHOFF

Hylocurus Eichhoff, 1872:133. Type-species: *Hylocurus elegans* Eichhoff, monobasic (Synonymy and references in Wood & Bright c1992:422)
Micracisoides Blackman, 1920:19. Type-species: *Micracis rudis* LeConte, subsequent designation by Wood 1982:608 (Synonymy and references in Wood & Bright c1992:422)

Diagnosis: Closely allied to *Micracis* except distinguished by the tuberculate posterior face of the protibia; by the shorter, oval eye; usually by the bisinuate sutures of the antennal club (strongly procurved in a few species); and by the more slender protibia.

Description: Species small to medium size (1.3–3.5 mm), body stout to rather slender (2.2–3.3 times as long as wide); sexes of about equal size; frons mostly convex in male, occasionally in female, a transverse, subcarinate elevation sometimes present, female often flat to variously concave, with or without ornamental vestiture; antennal club usually short, slender to expanded, sometimes with tufts of long hair, funicle 6-segmented, club subcircular to elongate, sutures bisinuate to very strongly procurved. Pronotum usually longer than wide, anterior slope declivous, asperate. Elytra usually sexually dimorphic, more elaborately sculptured in male, sometimes bearing nodules, spines, or variously truncate. Protibia usually wider near its apex, posterior surface armed by tubercles.

Biology: All observed species are bigynous and xylophagous.

Distribution: Wood & Bright (c1992:422–429) record 75 species in this genus from North and South America and the Antilles Islands; 29 species were listed from South America.

Key to the Species of *Hylocurus*

- 1. Crest of declivital interstriae 9 separated from costal margin by an impressed groove of striae 9, tubercles or nodules of interstriae 1–8 precede base of declivity, sometimes extending to middle of disc 2
- Elevated crest of declivital interstriae 9 continuing to and joining costal margin, not interrupted by striae 9 (except a very narrow interruption in *retusipennis*, couplet 27); tubercles usually absent on disc anterior to base of declivity 22
- 2(1). Tubercles of declivital interstriae 9 continuing almost to interstriae 3 (2, 4–6 continued to their apices), 3 not elevated, its tubercles about equal to those of 4 and 5; costal margin at declivity either smooth or moderately to strongly nodulate; declivital surface mostly rugose-reticulate 3

- Tubercles of declivital interstriae 9 often ending remote from 3, with 3 often a significant elevation, costal margin at declivity weakly or never nodulate; interstriae 3 usually elevated on basal half of declivity, its tubercles often conspicuous, those on 4–6 usually reduced in size and number to absent 11
- 3(2). Discal striae with punctures rather small, shallowly impressed, interstriae as wide or wider than striae, punctures smaller than those of striae, not at all granulate on disc, sometimes very weakly granulate at base of declivity, small granules continue on declivity to apices on interstriae 1–9, granules narrow, not as high as wide, subacutely pointed; declivity much steeper than usual 4
- Discal striae with punctures moderately to very coarse, deep, interstriae conspicuously narrower than striae, those on disc near declivity sometimes armed by moderately coarse nodules, reduced granules or tubercles continue to declivity; declivity rather steep, mucro longer, more acutely pointed; declivity mostly reticulate from base to apex 5
- 4(3). Larger species; discal interstriae on basal third twice as wide as striae, only slightly wider at base of declivity; frons punctured; anterior margin of pronotum serrate; male declivital interstriae 9 on basal half with setae uniseriate; Brazil; 2.4–2.5 mm *errans* Blandford
- Smaller species; discal interstriae on basal third of disc as wide as striae, narrower than striae at base of declivity; frons with punctures obscure to obsolete, replaced by rather coarse tubercles; anterior margin of male pronotum not serrate, submargin with 4 serrations, strongly reticulate on posterior half; declivital setae rather slender, each 6–10 times as long as wide; male declivital interstriae 9 with setae on basal half more numerous and confused (uniseriate in female); Argentina; 1.9–2.2 mm (see also *vagabundus* Blandford, *longulus* Nunberg) *vianai* Schedl
- 5(3). Declivital interstriae 2, 4, and 6 each with a row of tubercles to their apex (in male brasiliensis reduced on 2 and 6 of female) 6
- Female scape (sometimes male also) flattened and ornamented by conspicuous hair; declivital interstriae 2, 4, and 6 either devoid of tubercles or these visible only on basal half or less 8
- 6(5). Body size smaller; color reddish brown; interstitial nodules on disc at base of declivity small, poorly formed in male, absent in female; interstitial scales at base of declivity each two to four times as long as wide in male, slender in female (more than 10 times as long as wide); Brazil (Mato Grosso); 1.9–2.0 mm *brasiliensis* Nunberg
- Body size larger; color darker; interstitial nodules on disc near declivity usually present in male 7
- 7(6). Strial punctures on posterior half of disc only slightly larger near base of declivity; interstitial tubercles on lower half of declivity of about equal size from 1 and 3–9 reduced to absent on 2; female scape triangularly flattened and ornamented by long hair; female frons from epistoma to vertex with abundant pubescence; longest interstitial setae on declivity equal in length to distance between rows; Brazil (Sao Paulo); ETOH trap; 2.5–2.7 mm *subgranulatus* Schedl
- Strial punctures on anterior half of disc of normal size, those on posterior half greatly enlarged, more than twice as large as those near base; interstitial tubercles on lower half of declivity on 3–9 distinctly larger than on 1 and 2; longest interstitial setae on declivity distinctly longer than distance between rows; Brazil (Sao Paulo?); 2.2–2.3 mm *flechtmanni* Wood
- 8(5). Discal interstriae wider than striae, most punctures two-thirds as large as those of striae; interstitial granules at base of declivity very small, rounded; declivital interstriae 1 and 3 each with a row of small tubercles from base almost to apex, 4–8 with a few tubercles only at base of declivity; erect interstitial setae strongly flattened; color reddish brown; Brazil (Sao Paulo); 1.7–1.8 mm *obtusipennis* Schedl
- Discal interstriae narrower than striae, strial punctures larger, deeper, interstitial punctures smaller; interstitial tubercles at base of declivity rather coarse 9

- 9(8). Elytral declivity rugose-reticulate, dull; discal interstriae twice as wide as striae; male frons with a transverse carina, female frons pubescent; female scape strongly flattened, male weakly, pubescence elaborate in female, moderate in male; Brazil (Santa Catarina); 3.2–3.5 mm *giganteus* (Schedl)
- Elytral declivity smooth, brightly shining, 2 armed by a row of fine tubercles on basal half; discal interstriae as wide as striae; male frons without a transverse carina; female scape slightly flattened, ornamented by fewer setae 10
- 10(9). Body larger, stouter, 2.9 times as long as wide; interstitial setae much longer, hairlike; strial punctures on disc coarse, deep; discal interstriae on basal two-thirds about as wide as striae; interstitial nodules near base of declivity moderately coarse in female, very coarse in male; Brazil (Santa Catarina); 2.7–2.9 mm *impar* Schedl
- Body smaller, more slender, 3.1 times as long as wide; interstitial setae rather short, strongly flattened, each scale about three times as long as wide; strial punctures on disc small, shallow; discal interstriae on basal two-thirds about as wide as striae; interstitial nodules near base of declivity moderately coarse in female, very coarse in male; Brazil (Bahia); 2.3 mm *interpositus* Schedl
- 11(2). Elytral declivity reticulate to rugose-reticulate in both sexes (dull) 12
- Elytral declivity with surfaces mostly, smooth, shining in both sexes (some reticulation on interstriae 1 in two species) 15
- 12(11). Frons in both sexes armed by about 20 small to moderately large, confused tubercles from middle to upper level of eyes, no indication of a transverse carina; tubercles at apex of declivital interstriae 9 smaller, obsolete before apex, tubercles on 3 obsolete on lower half, setae on 2 uniseriate to apex 13
- Frons more finely granular in both sexes, a transverse carina sometimes present on less than median fourth; apex of declivital interstriae 9 ending in an acutely pointed spine, 3 with a small spine near middle, setae on 2 obsolete on lower half 14
- 13(12). Costal margin of elytra feebly descending near apex then gradually ascending to terminal mucro, mucro larger, more acutely pointed; interstitial nodules at base of declivity smaller, most more nearly resembling tubercles; Brazil (Santa Catarina); 2.4–2.5 mm *pilosus* Schedl
- Costal margin of elytra descending moderately near apex then rather abruptly ascending to point in line with striae 2, terminal mucro smaller, more obtuse, angle from costal margin to mucro rather abrupt; interstitial nodules at base of declivity larger, more broadly rounded; some setae at base of male declivity much more slender and longer than others; Brazil (Santa Catarina); 2.8–3.1 mm *robustus* Schedl
- 14(12). Frontal transverse carina usually on less than median fourth; interstitial tubercles near declivity on male disc narrow, higher than wide; setae on declivital interstriae 1 slender, hairlike; Venezuela; *Inga*; 1.4–1.9 mm *verrucosus* Wood
- Transverse carina on frons about half as wide as frons; interstitial tubercles near declivity of male wider than high, setae on declivital interstriae 1 stout, almost scalelike; some males lack declivital reticulation; Brazil (Rondon); 2.1–2.4 mm *plaumanni* Wood
- 15(11). Discal predeclivital interstriae smooth (with uniseriate punctures); male base of declivity abrupt, interstriae 1, 3, 5, 7 each ending in a spine (forming a circumdeclivital ring); female frons without a transverse carina, male frons with a weak transverse carina 16
- Predeclivital interstriae armed by granules or conspicuous nodules (small in female, larger in male); frons with a transverse carina in both sexes 18
- 16(15). Interstitial spines in male circumdeclivital ring at base of declivity on 1–8 of equal length, projecting slightly; male and female frons flattened to feebly concave, densely, broadly pubescent

- from level of antennal insertion almost to vertex; female scape slightly flattened and pubescent in both sexes (club longer than wide, suture 1 almost straight, not attaining middle of club length); upper half of declivital interstriae 3 armed by one to three tubercles; Venezuela to Brazil (Santa Catarina); 1.8–2.0 mm *discifer* Eichhoff
- Interstitial spines in circumdeclivital ring conspicuously longer on odd-numbered interstriae (1, 3, 5, etc.) 17
- 17(16). Male terminal mucro at elytral apex wider, profile from dorsal aspect forming a 90 degree angle; apex of declivital interstriae 9 more obtuse, shorter (less than one-fourth as long as mucro); odd-numbered spines in circumdeclivital ring obtusely, sharply pointed; female frons rather sparsely pubescent; Mexico (Colima) to Costa Rica; 1.5–2.3 mm *inaequalis* Wood
- Male terminal mucro more slender, forming a 60 degree angle from dorsal aspect; apex of declivital interstriae 9 longer, projecting more than one-fourth length of mucro; spines in circumdeclivital ring blunt, tips rounded; female not seen; Venezuela; 1.7–1.9 mm *alternatus* Eggers
- 18(15). Antennal club subcircular, with suture 1 obsolete on more than central two-thirds, a few setae present at margins, 2 rather strongly procurved, almost attaining apex; stria punctures rather strongly impressed, discal striae near declivity distinctly wider than interstriae; interstitial nodules confined to posterior fourth of disc, rather small, wider than high 19
- Antennal club with suture 1 obsolete on central third, visible at sides, 2 attaining two thirds club length from base; striae less strongly impressed, those near base of declivity narrower than interstriae; interstitial nodules confined to posterior third of disc, nodules each higher than wide 20
- 19(18). Declivital interstriae 1 armed on basal half by a row of six or more small, pointed tubercles, spine on 3 at middle of declivity much smaller, not higher than wide; interstitial nodules on male disc near declivity small, each about twice as wide as high; erect setae at base of declivity slender, sharply pointed; Colombia; 2.0–2.3 mm *colombianus* Wood
- Declivital interstriae 1 armed near base by one small tubercle, spine on 3 at middle of declivity large, at least twice as long as its basal width; interstitial nodules on male disc near declivity large, about as wide as high; erect setae at base of declivity stout, blunt; Brazil (Bahia); 2.7 mm *acutedentatus* Schedl
- 20(18). Interstriae 9 near base of declivity ending in a large, rather bluntly pointed, somewhat projecting spine; interstriae on posterior third of disc each armed by about four to five coarse, acutely rounded nodules, each slightly higher than wide; face of declivity with one small, pointed tubercle near apex of interstriae 3; male transverse frontal carina occupying median three-fourths; Brazil (Santa Catarina); 2.0 mm *trispinatus* Schedl
- Apex of declivital interstriae 9 only weakly elevated, not projecting into a major denticle, 3 and 9 each with several small denticles on basal half 21
- 21(20). Strial punctures on disc very small, interstriae almost smooth on basal half, nodules on posterior third very small, not strongly elevated; setae on and near declivity moderately long, of rather slender hair (female?); transverse frontal carina very short, on median one fifth; Colombia; 1.8 mm ? female *nodifer* Wood
- Strial punctures on disc of small to moderate size, interstitial nodules as wide as an interstriae, rather coarse, 2–4 nodules on each interstriae at or near base of declivity; setae on and near declivity moderately long, rather stout, blunt (male); transverse frontal carina occupying more than median half; Colombia; 2.0 mm male of *nodifer* Wood
- 22(1). Antennal club as wide or wider than long, sutures moderately, somewhat broadly procurved, female scape short, simple, ornamented by several setae randomly distributed; elytral declivity more nearly convex, sometimes with spines either of unequal length or on alternate interstriae at base of declivity, some odd-numbered declivital interstriae armed by rows of granules 23

- Antennal club conspicuously as long to longer than wide, sutures broadly to very strongly, narrowly procurved, female scape sometimes unusually configured and elaborately ornamented by small tufts of long setae; male declivity with a circumdeclivital ring of tubercles usually of equal length on interstriae 1–7 and a lateral costa to sutural apex, with no tubercles or granules on face of declivity 26
- 23(22). Male elytral declivity with at least two or three granules present on basal half of declivital interstriae 1–7; male without a broken circumdeclivital ring of enlarged tubercles on odd numbered interstriae at base of declivity; female frons ornamented by a dense brush of long hair 24
- Male declivity usually with even-numbered interstriae unarmed by granules, base of declivity on even-numbered interstriae with a large tubercle or spine (forming a circumdeclivital ring), odd-numbered interstriae usually with a series of much smaller tubercles; females not seen 25
- 24(23). Male frons with a conspicuous transverse carina on median half at upper level of eyes; female frons shallowly concave from epistoma to vertex and uniformly ornamented by a rather dense brush of hair of uniform length; elytral declivity rugose-reticulate from its base to apex, even-numbered interstriae with tubercles obsolete on lower half; declivital setae slender, all in uniseriate rows, each seta more than eight times as long as wide; Venezuela (Barinas); 2.1–2.5 mm *singularis* Wood
- Male frons without a transverse carina; female frons flattened from epistoma to vertex, ornamented by a dense brush of hair; setae on upper margin conspicuously longer; elytral declivity mostly shining, obscurely rugose-reticulate only on and near apex, all interstriae with tubercles continuing to their apex; declivital setae stout, mostly four to six times as long as wide, much more abundant, confused; Venezuela (Aragua); tree branch; 2.1–2.5 mm *villifrons* Wood
- 25(23). Declivity rugose-reticulate from base to apex; at base of male declivity interstriae 2, 4, and 6 strongly elevated into a blunt spine, spines projecting feebly, small tubercles continuing down face of declivity on 1, 3, 5, and 7, short, stout setae continuing on face on interstriae 1–7; antennal insertion in usual position near eye; Peru; 2.6 mm *woytkowskii* Wood
- Declivity mostly shining; circumdeclivital spines on 2, 4, and 5 moderately coarse, projecting, 3 with a very large, laterally compressed, pointed spine projecting and curving ventrad, 8 with a small spine, 9 with a coarse spine (equal to 7), costal margin with a small spine in line with interstriae 4; antennal insertion strongly displaced dorsad and mesad (to midway between epistoma and upper level of eyes); Brazil; 2.0 mm *spinifex* Blandford
- 26(22). Antennal club small, as wide as long, sutures broadly to moderately procurved, not attaining middle of club; male frons with a short, distinct transverse carina equal in length to one fourth distance between eyes; male declivity with tubercles on interstriae 3 on face 27
- Antennal club conspicuously longer than wide, sutures very strongly, narrowly procurved, 1 attaining middle of club or beyond; declivital face of male without any tubercles inside of circumdeclivital ring (minute tubercles on sutural interstriae in 1 species) 28
- 27(26). Crest at apex of declivital interstriae 9 narrowly separated from costal margin by striae 9, crest of 9 ending abruptly; face of male declivity convex, including immediately inside of circumdeclivital spines; female frons broadly convex, shining, minutely punctured, sparse setae uniformly distributed; Brazil (Santa Catarina); 1.9–2.1 mm *retusipennis* Blandford
- Crest of declivital interstriae 9 attaining and joining costal margin; face of male declivity concavely impressed immediately inside of circumdeclivital ring of spines; female frons somewhat flattened, marginal areas rugose, margins on upper half bearing a dense brush of moderately long, subplumose setae, setae sparse, inconspicuous on lower half; Mexico (Nayarit) to Colombia; *Acacia* and other Leguminosae; 1.3–1.5 mm *elegans* Eichhoff
- 28(26). Peripheral third of declivital face (immediately inside of circumdeclivital ring) not subconcavely impressed, striae punctures clearly in rows on peripheral third, setae on declivital face moderately abundant, short, stout (not scalelike) or absent; sutural interstriae on declivity with several small tubercles 29

- Marginal third of declivital face subconcavely impressed, striae punctures confused (2 punctures in a row on many); setae on elytral declivity either all hairlike or all scalelike; female scape remarkably sculptured (with flattening or lateral extensions and tufts of setae) 31
- 29(28). Interstitial circumdeclivital spines on male declivity of unequal size, those on interstriae 1, 2, 4, 6, and 8 comparatively small, those on 3 very large, 5 and 7 moderately large; declivital face glabrous; sutural interstriae on face of declivity armed by about two to five minute tubercles; female not seen; Brazil (Parana); 3.0 mm *inaequidens* Wood
- Interstitial spines on circumdeclivital ring of male small, of about equal length (most projecting little or not at all); declivital face with setae; female not seen 30
- 30(29). Interstitial spines on circumdeclivital ring in male very small to no more than a callus; declivital face with setae short, rather stout; male frons closely, coarsely punctured on central half, without tubercles; color reddish brown; Venezuela (Aragua); 2.8–3.1 mm *declivis* Wood
- Interstitial spines on male declivital ring small, all projecting slightly; setae on declivity very slender, longer; color very dark reddish brown; Brazil (Rio Grande do Sul); 2.3–2.6 mm *aequalis* Wood
- 31(28). Setae on elytral declivity of slender hair; female frons almost flat, densely, finely punctured, a strong transverse carina at vertex, vestiture sparse, moderately long, uniformly distributed; scape with one reddish amber and two pale yellow tufts of long hair; anterior margin of female pronotum normal; Brazil (Santa Catarina); 2.4–2.8 mm *dimorphus* (Schedl)
- Setae on elytral declivity of abundant, short scales, each about two to three times as long as wide; female frons deeply, broadly, longitudinally sulcate (concave), vertex bearing a large tuft of long reddish amber hair; scape with two small tufts of reddish amber setae and a broader tuft of yellow hair; anterior margin of female pronotum conspicuously emarginate on median area; Venezuela (Aragua); *Nectandra* branches; 1.9–2.5 mm *flagellatus* Wood

Hylocurus errans Blandford

Hylocurus errans Blandford, 1898:224. Lectotype ♂; “Mexican” [actually Brazilian] tobacco refuse intercepted at Paris; BMNH, London, designated by Wood 1982:625 (References in Wood & Bright c1992:424)

Hylocurus denticollis Schedl, 1976:71. Holotype ♂; Encruzilhada 980 m, Bahia, Brazil; NHMW, Wien (References in Wood & Bright c1992:423). *New synonymy*

Diagnosis: Distinguished by the rather large male antennal club, with suture 1 strongly procurved, attaining middle of club length; by the pronotum being punctured on posterior half of area behind summit; and by the comparatively simple elytral declivity, as described below. Originally reported from “Mexican” tobacco refuse intercepted at Paris; however, all specimens so labeled and reported by Blandford (1898) are now known to have originated in Brazil.

Male: Length 2.4–2.5 mm, 2.9 times as long as wide; color very dark reddish brown. Frons broadly convex from epistoma to vertex; surface coarsely, somewhat rugosely punctured; vestiture not evident. Antennal club slightly longer than wide (1.5 times), distinctly longer than scape; scape simple, club-shaped; club suture 1 rather broadly arched, attaining middle of club length, suture 2 clearly visible. Pronotum 1.5 times as long as wide; summit distinctly in front of middle of pronotum length; anterior

slope strongly declivous, closely, rather strongly asperate; anterior margin irregularly serrate, about six serrations; surface behind summit reticulate, rounded granules extending from summit half distance toward posterior margin, posterior half mostly punctured, a few minute granules evident; vestiture apparently restricted to asperate area, short, recumbent. Elytra 1.8 times as long as wide, 1.5 times as long as pronotum; striae not impressed at base, moderately impressed by base of declivity, punctures small at base, almost twice as large at base of declivity; interstriae twice as wide as striae at base, slightly narrower than striae at base of declivity, surface dull, punctures much smaller than those of striae, uniseriate. Declivity occupying about one-fourth of elytra length, steep, convex, terminal mucro acute, moderately produced; striae 1–3 less distinctly impressed, most of their punctures containing a tubercular elevation (giving them a subocular appearance), interstriae not elevated, each bearing a uniseriate row of small tubercles, most obsolete before apex; surface weakly reticulate.

Distribution: Brazil: Labeled “Mexican tobacco,” recovered from tobacco crate refuse at Paris that was thought to have originated in Mexico; however, the species so labeled are known to have come from Brazil (Wood 1982: 399); Encruzilhada, Bahia, XI-1972, 980 m, M. Alverenga.

Notes: The above treatment was based on the male lectotype of *errans*, presumably from Brazil, and on the male holotype of *denticulatus* from Brazil.

Hylocurus vianai Schedl

Hylocurus vianai Schedl, 1952:457. Lectotype ♂; Tigre, Buenos Aires, Argentina; NHMW, Wien, present designation (References in Wood & Bright c1992:428)

Hylocurus intermedius Schedl, 1952:458. Lectotype ♀; Pilar, Argentina; NHMW, Wien, present designation (References in Wood & Bright c1992:426). *New synonymy*

Diagnosis: Distinguished from *obtusipennis* Schedl by the slightly larger body size; by the strongly reticulate (not rugose-reticulate) pronotum; by the more widely spaced, more slender interstitial setae; by the larger tubercles on the frons; and by the slightly larger interstitial tubercles on the declivity.

Male: Similar to female except frons shallowly impressed on area below upper level of eyes, with tubercles much smaller; interstitial setae on and near declivity longer and more slender.

Female: Length 1.9–2.2 mm, 2.8 times as long as wide; color dark reddish brown, vestiture pale. Frons convex almost to epistoma; surface reticulate and with several randomly placed, coarse tubercles; vestiture sparse, inconspicuous. Scape with many scattered setae (more than on male); club small, sutures 1 and 2 distinct, moderately procurved. Pronotum 1.0 times as long as wide; sides on basal half almost straight, feebly converging toward broadly rounded anterior margin, about four submarginal crenulations evident; surface strongly reticulate to feebly rugose-reticulate, anterior area asperate, a few scattered granules on disc; vestiture a mixture of slender and stout setae of moderate abundance. Elytra 1.75 times as long as wide, 1.75 times as long as pronotum; striae not impressed, punctures moderately large, shallow, distinct; interstriae slightly wider than striae, almost smooth, shining, somewhat irregular, punctures uniseriate, each about a fourth as large as those of striae, margins of punctures near declivity feebly tuberculate. Declivity steep, strongly convex; striae punctures slightly smaller than on disc; interstitial punctures replaced by small, pointed tubercles to apex (slightly smaller in male). Vestiture of slender, rather short striae hair; and interstitial rows of erect, stout bristles, each as long as distance between rows on declivity, slightly shorter on disc, each about 6 times as long as wide on disc, about 8 times on declivity (slightly longer on male).

Distribution: Argentina: Buenos Aires, X-1939, 46, M.J. Viana (type of *intermedius*); Buenos Aires, Tigre, X-1939, M.J. Viana (non-type of *intermedius* and lectotype, lectoallotype, and 1 paratype of *vianai*), same except VII-1948, 42 (1 paratype; 3 female and 1 male mounted together on separate paper points on one pin), same data except IV-1950, *Acacia negra* (1 male det. Schedl).

Hosts: *Acacia negra*.

Notes: The above treatment was based on the male “holotype,” on 1 male paratype, and on 2 other males of

vianai Schedl det. Schedl; on the female holotype of *intermedius* Schedl, on the allotype (also a female, not a male as labeled), on 2 female paratypes (one erroneously labeled as a male), and on 1 male and 3 females on 1 pin identified by Schedl. Schedl (1979:126–127) subsequent to the original description designated a “female holotype” and a “male allotype” (also a female, not a male), contrary to procedure specified in the International Code on Zoological Nomenclature. I here designate his “female holotype” as the lectotype of *Hylocurus intermedius* Schedl. The only male seen by me is the non-type specimen, cited above, from the type locality but taken on a subsequent date. I also designate the male syntype (Schedl’s “holotype”) as the lectotype of *Hylocurus vianai* Schedl, as indicated above. Because only 1 species is represented, I exercise the first revisor option and select *vianai* as the valid name for this species.

Hylocurus vagabundus Blandford

Hylocurus vagabundus Blandford, 1898:224. Holotype ♀; “Mexican” [actually Brazilian] tobacco refuse, intercepted at Paris; BMNH, London (References in Wood & Bright c1992:428)

Diagnosis: This species is not in the above key, although it keys to *vianai* Schedl. It is allied to *nodulus* Wood (1956:141), from Mexico to Costa Rica. The female lectotype was examined during this study, but unfortunately the females have poorly formed characters and cannot be distinguished. Several requests for paratype males, for lectoallotype selection, were not answered. A description of the holotype is presented here.

Male: Not available for comparison.

Female: Length 1.8 mm, 2.9 times as long as wide; color almost black. Frons convex and weakly rugose-reticulate above, transversely impressed, almost flat and smooth below upper level of eyes; vestiture on upper area very sparse, minute. Pronotum 1.16 times as long as wide; sides on basal two-thirds almost straight and converging very slightly toward rather narrowly rounded anterior margin; summit slightly anterior to middle of pronotum length; asperities rather coarse, close, confused, transverse rugae mark summit; disc weakly rugose-reticulate, median third with small laterally compressed tubercles to base, punctures obsolete; lateral areas obscurely punctured; vestiture not evident (abraded?). Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; disc occupying basal 68 percent of elytra length; discal striae not impressed, punctures in rows, rather strongly impressed; interstriae as wide as striae, punctures mostly obsolete except near declivity, most weakly subtuberculate. Declivity very steep, strongly convex; declivital interstriae 1 and 3 feebly elevated, each armed by a row of 6–8 small, pointed tubercles to their apex, 2 feebly impressed, unarmed except for about three small tubercles at base; interstriae 4–9 each armed by two or more small tubercles on or near base. Vestiture restricted to declivital interstriae, sparse, very short, each as long as

wide on 1–3, about four to six times as long as wide on 4 and 5.

Distribution: Intercepted at Paris in tobacco refuse from Brazil.

Notes: The above treatment was based on the female holotype. In 1983, Blandford's entire series was examined. Males differ from females in having interstitial nodules on the posterior half of the elytral disc. My memory, after 21 years, is that the nodules on male *vagabundus* are smaller and more regular in distribution than in *nodulus*. This observation requires confirmation.

Hylocurus longulus (Nunberg), n. comb.

Hylocurus longulus (Nunberg), 1956:135 (*Micracis*); Badenfurt, Brazil; IZW, Warsaw (References in Wood & Bright c1992:433)

Diagnosis: Apparently allied to *vianai* Schedl, but larger, except female pronotum 1.4 times as long as wide. Elytra more slender (1.9 times as long as wide). The short, oval eye and the tuberculate posterior face of the protibia require that this species must be transferred from *Micracis* to *Hylocurus*.

Female: Length 3.0 mm, 2.8 times as long as wide; color very dark reddish brown. Frons rather strongly convex; median third smooth, shining to slightly above upper level of eyes, lateral areas with numerous, close, rounded granules; glabrous above, with many short to moderately long setae on lower half. Pronotum 1.14 times as long as wide; sides almost straight and parallel on basal half, rather narrowly rounded in front; anterior margin armed by 6 very weak serrations; summit anterior to middle of pronotum length; anterior slope steep, with numerous small, confused asperities; posterior areas subshining, with many small rounded granules on median third, becoming obscurely reticulate on lateral areas; vestiture mostly abraded, of rather abundant, short, hairlike setae. Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures rather small, close, moderately deep, interior of some punctures obscurely reticulate; interstriae about as wide as striae, shining, not smooth, punctures small, about one-third as large as those of striae, anterior margin of most punctures weakly elevated. Declivity occupying 22 percent of elytra length; steep, convex, apical mucro moderately acute; surface obscurely reticulate, about as on disc except interstitial punctures replaced by closely spaced small tubercles, their height equal to less than their basal width, about one-third of tubercles on 1–8 mostly obsolete. Vestiture mostly restricted to posterior half of elytra length (abraded on anterior half?), consisting of minute strial hair, and interstitial rows of erect, stout, blunt setae spaced between rows by length of a seta and within a row by less than length of a seta.

Distribution: Brazil: Badenfurt, 1946, P. Kessel.

Notes: The above treatment was based on the female holotype.

Hylocurus brasiliensis Nunberg

Hylocurus brasiliensis Nunberg, 1956:208. Lectotype ♂; Rio Caraguata, Mato Grosso, Brazil; NHMW, Wien, replacement name, automatic (Synonymy and references in Wood & Bright c1992:423)

Hylocurus simplex Schedl, 1954:33. Lectotype ♂; Rio Caraguata, Mato Grosso, Brazil; NHMW, Wien, present designation, name preoccupied by Blandford 1898:222

Hylocurus rectus Schedl, 1958:144. Lectotype ♂, automatic; Rio Caraguata, Mato Grosso, Brazil; NHMW, Wien, unneeded replacement name

Diagnosis: Distinguished from *subgranulosus* Schedl by the smaller strial punctures in both sexes; by the reduced size and extent of nodules on male interstriae near the declivity; and by the much broader male interstitial scales near the base of the declivity.

Male: Length 1.9–2.0 mm, 2.8 times as long as wide; color reddish brown, vestiture pale. Frons of type not visible, concealed by pronotum. Antennal scape slender, slightly shorter than club, ornamented by a small tuft of about six long setae, club with sutures 1 and 2 clearly marked, strongly procurved, suture 1 attaining middle of club length. Pronotum 1.1 times as long as wide; summit slightly anterior to middle of pronotum length; sides weakly arcuate on posterior half then converging to broadly rounded anterior margin; anterior margin armed by six subcontiguous median serrations; surface finely rugose-reticulate; anterior slope rather coarsely asperate, several small granules on disc, posterolateral areas with a few shallow punctures; vestiture of stout bristles on asperate area, mostly abraded behind. Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures rather large, deep; interstriae very slightly narrower than striae, shining, punctures uniseriate, each about half as wide as those of striae on basal three-fourths of disc, replaced near base of declivity by small tubercles. Declivity strongly convex, steep; surface finely rugose-reticulate, 1 to 8 each armed by a row of small, pointed tubercles, those on 1, 3, and 7 extending to apex, those on 2, 4, and 6 mostly obsolete below middle. Vestiture mostly abraded on disc of type, on and near declivity consisting of minute strial hair and interstitial rows of erect scales, each scale about two to four times as long as wide, at base about two-thirds as long as distance between rows, smaller below to obsolete on lower half.

Female: Similar to male except frons convex above, impressed and shallowly concave on lower half; surface of frons rugose-reticulate, sparsely pubescent; anterior margin of pronotum unarmed by serrations; tubercles on disc near base of declivity smaller, less numerous; interstitial tubercles on declivity larger, usually continuing to apex on interstriae 2, 4, and 6; vestiture on declivity interstriae consisting of slender bristles.

Brazil: Mato Grosso, Rio Caraguata, 2-III-1953, F. Plaumann.

Notes: The above treatment was based on the 2 syntypes in the Schedl series at NHMW, Wien. Schedl

(1979:230) designated these syntypes as the “male holotype” and “female allotype” for this species subsequent to the original description. I here designate Schedl’s “holotype” as the male lectotype and his “allotype” as the female lectoallotype of *Hylocurus simplex* Schedl, a preoccupied name, as indicated above.

Hylocurus subgranulatus Schedl

Hylocurus subgranulatus Schedl, 1954:31. Lectotype ♀ Rio Caraguato, Mato Grosso, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:428)

Diagnosis: Discal interstriae of male as wide as striae, nodules at and near base of declivity moderately coarse, rather narrowly rounded, variable; declivital striae 1–3 with punctures equally coarse, rather strongly impressed; similar to but larger than *flechtmanni* Wood; female scape triangularly flattened and pubescent, frons pubescent.

Male: Length 2.5–2.7 mm, 2.7 times as long as wide; color rather dark reddish brown, vestiture pale. Frons transversely impressed on median half of lower half, median fourth of impressed area impunctate, smooth, shining, remaining area weakly rugose-reticulate except for numerous shining, rounded tubercles randomly placed on upper two-thirds, vestiture rather coarse, moderately abundant, of medium length, more abundant on epistoma; a small tuft of hair on scape. Pronotum 1.0 times as long as wide, summit at middle, asperate to well behind summit, a few punctures near base; vestiture a mixture of fine and moderately coarse, suberect setae of medium length. Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; striae moderately impressed, punctures rather coarse, deep, except very near base punctures increase in size only slightly from anterior half to base of declivity, deep; interstriae smooth, shining about as wide as striae, punctures deep, less than half as wide as those of striae, anterior margin of their base slightly elevated (not tuberculate). Declivity convex, steep, moderately abrupt, mucro rather short; surface reticulate; striae slightly impressed, punctures moderately large, rather deep; interstriae as wide as striae, each (usually obsolete on 2) with a row of subacutely pointed tubercles, slightly smaller than at base, continued on all interstriae to near base of mucro, 9 slightly elevated to junction with 3. Vestiture of fine, short, obscure strial hair and uniseriate rows of erect, flattened interstitial scales; each scale on disc and on lower declivity as long as distance between rows, some of those near base of declivity 1.5 times as long, longest setae about eight times as long as wide.

Female: Similar to male, except frons densely, broadly pubescent from epistoma to vertex; scape strongly, triangularly flattened, a conspicuous tuft of long hair near apex; discal interstitial nodules near declivity absent; declivital interstitial tubercles on 1 and 2 usually absent.

Distribution: Brazil: Rio Caraguata, Mato Grosso, 2-V-1953, F. Plaumann.

Notes: The above treatment was based on the 5 male and 5 female syntypes in the Schedl series at NHMW, Wien. Schedl (1979:241) subsequent to the original description designated a “female holotype” and a “male allotype” from this series, contrary to the International Code on Zoological Nomenclature. I here designate that “holotype” (syntype) as the female lectotype and the “allotype” as the male lectoallotype for *Hylocurus subgranulatus* Schedl, as indicated above.

Hylocurus flechtmanni Wood, n. sp.

Hylocurus flechtmanni Wood: Holotype ♂; Agudos, Duraflora, Sao Paulo, Brazil; MZUSP, Sao Paulo, designated below

Diagnosis: Distinguished from *subgranulatus* Schedl by the smaller size, by the much larger strial punctures at the base of the male declivity; by the larger interstitial nodules at the base of the male declivity; and by the much smaller, shallow punctures on striae 1 and 2 of the male declivity.

Male: Length 2.2–2.3 mm, 2.5 times as long as wide; color dark reddish brown. Frons transversely impressed from epistoma three-fourths distance toward upper level of eyes, surface of impressed area transversely etched and with sparse, minute granules, upper margin of impression broadly (transversely) subcarinate, upper area above carina closely, rather coarsely granulate to vertex; vestiture in impressed area rather abundant, coarse, moderately long, shorter and less abundant above carina. Pronotum 1.1 times as long as wide; as in *subgranulatus*. Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; striae weakly impressed, punctures on basal one-fifth small, larger behind (up to twice as large at base of declivity); interstriae smooth, shining, as wide as striae on basal one-fifth, about half as wide at base of declivity, each with two or three nodules (each about as high as wide) at base of declivity, anterior area undulating on interstitial crest as nodules decrease in size (cephalad). Declivity convex, steep, mucro short; surface mostly reticulate, striae more distinctly impressed than on disc, punctures on 1 and 2 of reduced size to apex; interstriae 1–9 each armed by a row of moderately coarse, pointed tubercles to their apices, decreasing gradually in size below nodules. Vestiture of short, fine, uniseriate strial hair, and rows of erect interstitial scales, each scale at base equal in length to two-thirds distance between rows, as long or slightly longer than distance between rows at base of declivity, decreasing to half this length on lower declivity, each scale almost six (base) to eight times as long as wide.

Distribution: Brazil (Sao Paulo).

Type material: The male holotype and 3 male paratypes were taken at Agudos, Duraflora, Sao Paulo, Brazil, 7-VII-1984, 23-XII-1986, ETOH trap in *Pinus oocarpa* stand (AG-T, C.A.H. Fletchmann). The holotype and 1 paratype are in MZUSP, Sao Paulo, 2 paratypes are in the U.S. National Museum, Washington.

Hylocurus obtusipennis Schedl

Hylocurus obtusipennis Schedl, 1976:72. Holotype ♀; Encruzilhada, 980 m, Bahia, Brazil; NHMW, Wien (References in Wood & Bright c1992:426)

Diagnosis: Distinguished from other South American *Hylocurus* by the small size; by the obscure sexual dimorphism, female frons with transverse pair of tubercles at center of frons; and by the simple elytral sculpture.

Male: Length 1.8–1.9 mm, 2.6 times as long as wide; color almost black, vestiture pale. Frons essentially convex from epistoma to upper level of eyes except median half somewhat flattened; surface rugose-reticulate, punctures not evident, sparse, fine granules uniformly distributed; setae coarse, rather sparse, uniformly distributed; antennal club small, subcircular; sutures moderately procurved, 1 extending one-third, 2 two-thirds club length from base. Pronotum 1.0 times as long as wide; summit at middle; surface rugose-reticulate, anterior half also asperate; granules behind summit small; anterior margin unarmed; vestiture a mixture of slender and slightly stout, moderately long setae about uniformly distributed. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures moderately impressed, those near base rather small, gradually increasing in size by one-third at base of declivity; some striae punctures at base of declivity with a small internal elevation giving an obscure occulate appearance; interstriae at base slightly wider than striae, slightly narrower than striae at base of declivity, surface smooth, punctures small, close, their anterior margin slightly elevated (not granulate). Declivity convex, steep; weakly rugose-reticulate on lower third; mucro short; all striae extend to their usual apex; interstriae narrower than striae, each with a row of small, blunt tubercles on basal two-thirds, 9 only slightly elevated (as in female). Vestiture of uniseriate rows of fine, short striae hair, and erect scales, each scale two-thirds as long as distance between rows and almost four times as long as wide, distinctly shorter on basal one-third of disc, confused on 9 at base of declivity.

Female: Length 1.7–1.8 mm, 2.5 times as long as wide. Frons broadly convex; a transverse pair of moderately coarse tubercles at middle; largely concealed by pronotum in specimens at hand, apparently rugose-reticulate, vestiture sparse, short. Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures rather small, clearly impressed; interstriae slightly wider than striae, shining, irregular, punctures about two-thirds as large as those of striae, impressed, not tuberculate toward declivity. Declivity convex, steep, rugose-reticulate on lower two-thirds; striae 1 and 2 with punctures small, distinct; interstriae 1 and 2 weakly elevated and armed by a row of pointed tubercles, tubercles on 1 slightly smaller, becoming obsolete before apex, one to three tubercles near apex of 4 to 9, 9 weakly elevated to junction with 3. Vestiture of uniseriate rows of minute striae hair and erect inter-

striae scales, each scale about two-thirds as long as distance between rows, each about six times as long as wide on declivity.

Distribution: Brazil: Encruzilhada, Bahia, XI-1972, 980 m, M. Alvarenga (type); Pedra Azul, M. Gerais, 700 m, XI-1972, Seabra & Oliveira; Sao Paulo, Botucatu, Duratex SA, ETOH trap at patio de serraria (sawmill), *Pinus-Eucalyptus*, C. Fletchmann; “AG-DC, AG-DF” (presumably Sao Paulo state).

Notes: The above treatment was based on the female holotype of *obtusipennis* Schedl from M. Gerais, Brazil, and on 2 males and 6 females from Brazil (Sao Paulo).

Hylocurus giganteus (Schedl)

Plate LXII

Hylocurus giganteus (Schedl), 1950:152 (*Micracis*). Syntypes, sex?; Nova Teutonia, Santa Catarina; NHMW, Wien, and Plaumann Collection (References in Wood & Bright c1992:425)

Hylocurus pseudoimpar Schedl, 1954:30. Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:427). *New synonymy*

Hylocurus interruptus Schedl, 1959:548. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:426). *New synonymy*

Diagnosis: Distinguished from *impar* Schedl by the dull, rugose-reticulate elytral declivity; by the wider discal interstriae; and by the transverse male frontal carina.

Male: Length 3.2–3.5 mm, 2.8 times as long as wide; color reddish brown. Lower third of frons moderately, transversely impressed, impressed area more finely sculptured, with moderately abundant hair; upper margin of impression forming a transverse carina on median fifth; area above carina broadly convex, surface rugose-reticulate, moderately, uniformly granulate, low granules obscurely subvulcanate; vestiture on convex area erect, rather short, moderately abundant, most rather coarse; antennal scape short, slightly flattened, with moderately abundant hair, suture 1 attaining middle of club, narrowly, strongly procurved. Pronotum 1.06 times as long as wide; about as in preceding species; anterior margin armed by six serrations. Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; striae weakly impressed at base, moderately toward base of declivity, punctures rather small, deep; interstriae twice as wide as striae at base, about 1.5 times as wide at base of declivity, surface smooth, shining, punctures at least half as large as those of striae, their anterior margins slightly to strongly elevated, forming about three moderately large nodules on each on interstriae 1–6 at base of declivity. Declivity broadly convex, steep, mucro projecting moderately; surface rugose-reticulate; interstriae 2, 4, and 6 unarmed from base to their apex, 1 with a row of small tubercles decreasing in size from base, minute by base of mucro, 3 and 7 each with a sparse row of four moderately coarse tubercles, crest of 9 moderately elevated, ending gradually before level of 3. Vestiture restricted to less than posterior fourth, consisting of uniseriate rows of

minute strial hair and erect interstitial bristles, longest bristles at base of declivity, up to 1.5 times as long as distance between rows.

Female: Similar to male except frons without a carina, central half weakly subconcave and densely pubescent to well above upper level of eyes; scape with dorsal apical angle greatly extended (process longer than remainder of scape), tuft of hair greatly increased and extended; elytral nodules half as large, declivital tubercles smaller.

Distribution: Brazil: Nova Teutonia, Santa Catarina, IV-1941, F. Plaumann.

Notes: The above treatment was based on 1 female and 2 male paratypes of *Micracis giganteus* Schedl, on 1 female paratype of *interruptus* Schedl, and on 10 syntypes of *pseudoimpar* Schedl from Brazil. The syntypic series of *pseudoimpar* in NHMW, Wien, consists of 5 males of *robustus*, the first of which was, subsequent to the original description, labeled (Schedl 1979:201) as the "allotype" of *pseudoimpar*; the second and third specimens were labeled as "paratypes," the fourth and fifth (mounted on 1 pin) are non-types of *giganteus*; the 5 females in this series include 2 female syntypes of *giganteus*, the first was labeled "holotype," the second "paratype," the third and fourth specimens are female non-types of *giganteus*, the fifth is a male non-type. I here designate Schedl's "holotype" (syntype) as the female lectotype of *Hylocurus pseudoimpar* Schedl. Schedl's "allotype" was misidentified and has no status as a type. The species is, quite clearly, a *Hylocurus*, not a *Micracis*, where Schedl originally placed it.

Hylocurus impar Schedl

Plate LXII

Hylocurus impar Schedl, 1939:723. Holotype ♂; Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:425)

Diagnosis: Distinguished by the smooth, shining elytral declivity; by the narrower discal interstriae; and by the absence of a transverse male frontal carina.

Male: Length 2.7–2.9 mm, 2.6 times as long as wide; color dark reddish brown. Frons broadly, evenly convex, central area reticulate, impunctate and without tubercles, lateral and dorsal areas with small, rather numerous tubercles (no carina); vestiture short, sparse, confined to lateral and dorsal areas; antennal scape not flattened, setae sparse, club with suture 1 rather broadly procurved, not attaining middle of club length. Pronotum about as in *giganteus* Schedl. Elytra about as in *giganteus* except strial punctures much larger, deeper, discal interstriae as wide as striae, nodules narrower, higher. Declivity convex, steep, basic sculpture as in *giganteus* except surface smooth, punctures deeper, tubercles on 1–3 smaller, those on 4–9 much larger (rounded nodules), crest of costal margin at declivity undulating. Vestiture as in *giganteus* except interstitial setae more slender, almost hairlike, conspicuously longer.

Female: Similar to male except scape slightly flattened; tubercles on frons smaller, less numerous; nod-

ules on and near base of declivity and on declivity much smaller; undulation on costal margin on declivity obscure; pronotum 1.12 times as long as wide.

Distribution: Brazil: Rondon, Parana, 24°38'B, 54°07'L, 1950s, F. Plaumann; Nova Teutonia, Santa Catarina, X-1956, VII-1957, F. Plaumann.

Notes: The above treatment was based on 6 males and 2 females from Brazil. I compared 1 male directly to the male holotype.

Hylocurus interpositus Schedl

Hylocurus interpositus Schedl, 1976:71. Holotype ♂?; Encruzilhada, 930 m, Bahia, Brazil; NHMW, Wien (References in Wood & Bright c1992:426)

Diagnosis: Distinguished from *impar* Schedl by the smaller, more slender body; by the scalelike interstitial setae; by the much smaller, shallow punctures on the discal striae; and by other characters cited below.

Male (?): Length 2.3 mm, 3.1 times as long as wide; color very dark brown, vestiture pale. Frons not visible on type, concealed by pronotum. Scape triangularly flattened, almost as wide apically as long, a tuft of long hair (about 10 setae) at dorsal apical angle, another tuft of shorter setae (about 10) on dorsal margin of basal half; club as long as scape and funicle combined, elongate-oval; sutures obscure, almost obsolete, 1 strongly procurved, attaining a point slightly beyond middle. Pronotum 1.2 times as long as wide; sides on basal half almost straight, parallel, unarmed anterior margin broadly rounded; summit distinctly in front of middle, anterior slope rather coarsely, closely asperate; surface strongly reticulate, several rounded tubercles on disc from summit to base, punctures not evident in lateral areas; vestiture of sparse short bristles in asperate area, a few stout setae on posterior half. Elytra 2.0 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures small, shallow; interstriae twice as wide as striae on basal two-thirds of disc, slightly wider than striae behind, surface shining, minutely irregular (not smooth), punctures uniseriate, smaller than those of striae, except replaced near declivity by a row of six or more small, rounded nodules on 1–5. Declivity steep, convex; interstriae 1–9 each with a uniseriate row of small, rounded tubercles to near apex, 9 rather weakly elevated to junction with 3; mucro rather short. Vestiture of minute strial hair on declivity, and of uniseriate rows of erect interstitial scales from base to apex, each scale about two to four times as long as wide, spaced within a row by length of a scale, and between rows by two-thirds length of a scale.

Female (?): Not seen. Scape of holotype suggests it may be a female, not a male.

Distribution: Brazil: Encruzilhada, Bahia, XI-1972, 980 m, M. Alvarenga.

Notes: The above treatment was based on the holotype, from Brazil, that is presumed to be a male.

Hylocurus pilosus Schedl

Hylocurus pilosus Schedl, 1950:151. Lectotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, designated by Schedl 1979:194 (References in Wood & Bright c1992:426)

Diagnosis: Distinguished from *robustus* Schedl by the smaller body size; by the normal, acute terminal mucro of the elytra; by the smaller, less numerous interstitial nodules at the base of the declivity; and by the more uniformly short pubescence of the elytral declivity.

Male: Length 2.4–2.5 mm, 2.5 times as long as wide; color very dark brown, vestiture pale. Frons broadly convex on upper half to vertex, surface rugose-reticulate and armed by more than 20 coarse, confused tubercles; lower half rather strongly, transversely impressed; sculpture fine, almost smooth in median area; vestiture sparse, mostly abraded on type. Antennal scape club-shaped, not flattened, setae sparse, short. Pronotum 0.90 times as long as wide; sides moderately arcuate, converging toward broadly rounded anterior margin; anterior margin armed by six coarse serrations; surface rugose-reticulate; summit at middle, anterior slope rather coarsely asperate, several granules behind summit, sparse, shallow punctures on lateral areas. Elytra 1.8 times as long as wide, 1.9 times as long as pronotum; striae not impressed, punctures rather coarse, deep; interstriae as wide as striae at base, slightly narrower near declivity, shining, irregular, punctures obscurely uniseriate on basal half (each about half as wide as a striae puncture), replaced by rounded nodules on posterior third of disc, about six moderate nodules each on 1–3. Declivity steep, broadly convex; surface rugose reticulate; striae punctures small, obscure on lower half, interstriae 1–3 feebly elevated, a row of very small granules on upper two-thirds of 3, a few at base of 1; terminal mucro more acutely pointed, regular (obscurely resembling *robustus*). Vestiture of uniseriate interstitial setae, short and sparse on disc; longer, slender on base of declivity, of almost uniform length, longest setae almost equal in length to distance between rows.

Female: Similar to male except frons more finely sculptured; sparse tubercles small, impression not as abrupt or as deep; striae punctures smaller, interstriae without nodules, sparse tubercles usually present near base of declivity.

Distribution: Brazil: Nova Teutonia, Santa Catarina, VIII-1941, F. Plaumann.

Notes: The above treatment was based on the male lectotype, the female lectoallotype, and 1 male and 1 female paratype in NHMW, Wien.

Hylocurus robustus Schedl

Hylocurus robustus Schedl, 1952:456. Lectotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:427)

Diagnosis: Distinguished from *impar* Schedl by the coarse tubercles on the upper frons; by the smaller

punctures on the discal striae; by the much smaller interstitial nodules near the base of the declivity; and by the rugose-reticulate elytral declivity.

Male: Length 2.8–3.0 mm, 2.5 times as long as wide; color almost black, vestiture pale. Median half of lower half of frons transversely impressed, transversely etched, granules minute or absent; upper half to well above upper level of eyes coarsely, closely granulate; vestiture mostly erect, rather coarse above, finer below; scape not flattened, club with suture 1 rather broadly procurved, not attaining middle of club. Pronotum similar to *impar*. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; striae not impressed except near declivity, punctures rather small, distinct; interstriae twice as wide as striae, except 1.5 times as wide at base of declivity, punctures rather small, each with about three or four rather small nodules at base of declivity. Declivity broadly convex, steep; surface rugose-reticulate; striae 1–4 with punctures small, rather obscure; interstriae 1, 2, and 4 each with a row of granules, granules minute to obsolete, 3 with small tubercles on upper two-thirds moderately confused, pointed, small tubercles on 4–8 at least near base, 9 weakly elevated and unarmed by tubercles. Vestiture near and on declivity erect, rather coarse, blunt, longest setae at base 1.5 times as long as distance between rows, shorter on basal half (1.0 times as long as distance between rows).

Female: Similar to male except tubercles on upper frons half as large, nodules at base of declivity less than half as large; tubercles on declivity smaller; elytral vestiture more slender, extending to near base of disc.

Distribution: Argentina to Brazil.

Argentina: Misiones.

Brazil: Nova Teutonia, Santa Catarina, VIII-1941, F. Plaumann.

Notes: The above treatment was based on 7 male and 5 female syntypes from Brazil. Schedl (1979:212), subsequent to the original description, designated a “female holotype” and a “male allotype” from these syntypes, contrary to procedure designated by the International Code on Zoological Nomenclature. I here designate Schedl’s “allotype” as the male lectotype and his “holotype” as the female lectoallotype of *Hylocurus robustus* Schedl. The sexes were changed because the most diagnostic characters are on the male. The type series of *H. pseudoimpar* is composit and contains specimens of *robustus* (see above under *H. giganteus*).

Hylocurus verrucosus Wood

Plate LXIII

Hylocurus verrucosus Wood, 1971:28. Holotype ♂; 9 km S Barrancas, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:428)

Diagnosis: Distinguished by the small size; by the short transverse carina in both sexes; and by the elevation of declivital interstriae 9 ending in a pointed spine.

Male: Length 1.4–1.9 mm, 2.6 times as long as wide; color dark reddish brown, vestiture pale. Frons broadly

convex from epistoma to vertex; surface rugose-reticulate, with small granules mostly on upper half; a short transverse carina on median one-fifth to one-tenth slightly below upper level of eyes; vestiture of sparse hair; scape not flattened, club small, sutures broadly procurved, 1 and 2 dividing club into about equal thirds. Pronotum 1.1 times as long as wide; sculpture as in preceding species. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; striae not impressed on disc except weakly near base of declivity, punctures small on basal half, distinctly larger at base of declivity (1.5 times as large); interstriae almost twice as wide as striae on basal half, only slightly wider at base of declivity, surface smooth, punctures about half as large as those of striae, each with three to four rounded nodules at base of declivity, each nodule as wide as its interstriae, as high as wide. Declivity convex, steep; surface rugose-reticulate; basal third of interstriae 1 and 3 each with three or four small, pointed denticles; striae punctures small to almost obsolete; elevated basal part of interstriae 9 ending behind in a pointed spine. Vestiture of minute striae hair on and near declivity, and erect interstitial scales; some scales attain base, much shorter on basal half of disc, longest on and near declivity, longest scales 1.3 times as long as distance between rows.

Female: Similar to male except interstitial nodules at base of declivity small to almost obsolete, interstitial scales more slender, slightly shorter, spine at apex of elevation on declivital interstriae 9 smaller.

Distribution: Venezuela: 9 km S Barrancas, Barinas, 5-XI-1969, 150 m, *Inga*, SLW; Ocomare, Aragua, 1967, *Theobroma cacao*, B. Mendoza.

Biology: Specimens were removed from broken branches 2–5 cm in diameter. Two females were usually found with 1 male in a gallery system. The galleries were entirely typical of the genus.

Notes: The above treatment was based on the type series of 35 specimens and on 1 other specimen, all from Venezuela.

Hylocurus plaumanni Wood, n. sp.

Hylocurus plaumanni Wood: Holotype ♂; Rondon, Parana, Brazil; USNM, Washington, designated below

Diagnosis: Distinguished from *verrucosus* Wood by the much longer transverse frontal carina in both sexes; by the wider male interstitial nodules near the base of the declivity; by the larger antennal club; and by the slightly larger size.

Male: Length 2.1–2.4 mm, 2.7 times as long as wide; color dark reddish brown. Frons broadly convex, a transverse carina on median half slightly below upper level of eyes; a weak, transverse impression below carina, upper area rugose-reticulate between rugae, moderately rugose elsewhere; vestiture obsolete, not clearly evident; middle half of suture 1 on antennal club essentially obsolete. Pronotum 1.1 times as long as wide, about as in preceding species. Elytra 1.6 times as long as wide, 1.5

times as long as pronotum; striae not impressed on basal third of disc, slightly impressed at base of declivity, punctures small, distinct, spaces between punctures subacute near declivity; interstriae almost twice as wide as striae throughout, punctures about half as large as those of striae, their anterior margins weakly elevated at base, strongly toward declivity, becoming moderately large nodules on posterior half, about six nodules on each before base of declivity. Declivity very broadly convex, irregularly flattened, very steep; mucro obtuse, rather short; striae punctures obscure to obsolete; interstriae 1 feebly elevated, one small tubercle on its basal third, 2 slightly impressed, 3 weakly elevated to middle of declivity, its basal half armed by about four small, pointed tubercles, last one largest, 4–8 each with one or two tubercles or small nodules near base, 9 with crest modestly elevated on about basal third and ending in a small, pointed spine, crest of basal area with small, rounded, confused tubercles. Vestiture largely confined to nodulate area, of minute striae hair and erect interstitial bristles, each bristle rather stout, equal in length to distance between rows.

Female: Similar to male except nodules of posterior third of elytral disc very small, tubercles on upper declivity reduced to absent, erect interstitial bristles more slender, slightly shorter.

Distribution: Brazil (Parana)

Type material: The male holotype, female allotype, and 8 paratypes were taken at Rondon, Parana, Brazil, 1950s, 24°38'B, 54°07'L, 500 m, F. Plaumann. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Hylocurus discifer Eichhoff

Hylocurus discifer Eichhoff, 1878:300. Holotype ♂; Venezuela; Hamburg Museum, lost

Hylocurus bidentatus Schedl, 1950:149. Lectotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:423). *New synonymy*

Diagnosis: Distinguished by the small size; by the smooth, shining elytral surfaces (without interstitial nodules); by the densely pubescent female frons; and by the elytral declivity. Possibly allied to *singularis* Wood and *villifrons* Wood.

Male: Frons strongly, extensively pubescent as in female; scape club-shaped, with a small tuft of hair; elytral declivity obliquely truncate and armed by a circumdeclivital row of interstitial spines, spines rather small, projecting only slightly, interstriae 3 on face near middle of declivity length armed by two spines.

Female: Length 1.8–2.0 mm, 2.7 times as long as wide; color dark reddish brown. Frons apparently flattened (or weakly concave) from level of antennal insertion to vertex, densely covered by a brush of reddish yellow erect setae on median three-fourths from level of antennal insertion almost to vertex; scape club-shaped, ornamented by a rather large brush of long, yellow setae, club small, sutures 1 and 2 broadly procurved, 1 not

attaining middle of club. Pronotum 1.1 times as long as wide, about as in preceding species, except anterior margin only feebly serrate. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures rather large, deep; interstriae as wide as striae, smooth, brightly shining, surface not undulating, punctures uniseriate, each about one-third as large as those of striae. Declivity broadly convex, steep, mucro moderate, subacute; surfaces shining; striae punctures small, rather deep; interstriae 1 feebly elevated, with a row of small punctures, unarmed, 2 moderately impressed, very narrow (half as wide as striae), without punctures or tubercles, 3 joins 7, both feebly elevated, 3 with a row of about five small tubercles, last one largest, 9 rather weakly elevated, gradually declining behind, crest with a row of small tubercles. Vestiture confined to declivity, of rows of minute striae hair and rows of erect, slender bristles, each bristle slightly longer than distance between rows.

Distribution: Venezuela to Brazil.

Brazil: Nova Teutonia, Santa Catarina, IV-1941 (type series), X-1956, F Plaumann.

Venezuela: "Venezuela." (male holotype of *discifer*, and a Chevrolat male).

Notes: The above treatment was based on 4 male syntypes and 5 female syntypes of *bidentatus* Schedl, and on 1 other female from Brazil. Schedl's (1979:39) designations subsequent to the original description of a "female holotype" and "male allotype" are not valid under the International Code on Zoological Nomenclature. I here designate Schedl's syntype (his "allotype") as the male lectotype of *Hylocurus bidentatus* Schedl. His syntype that he labeled as the holotype is designated as the lectoallotype of this species. Because the sexes were reversed and the male has the most diagnostic characters for this species, the male was selected as the lectotype. Two males in the BMNH, London, identified by Sampson as *discifer* Eichhoff, are of this species. Because these 2 specimens from Venezuela fit the description of *discifer*, and because Sampson probably saw the Eichhoff type, Eichhoff's name is used for this species. It is presumed that these Sampson males came from Colonia Tovar, Aragua, taken by Dr. Moritz, near his home. It is entirely possible that these were part of the original Eichhoff series.

Hylocurus alternatus Eggers

Hylocurus alternatus Eggers, 1951:153. Holotype ♂; Venezuela; NHMW, Wien (References in Wood and Bright c1992:422)

Diagnosis: Distinguished from the allied *inaequalis* Wood by the smaller size; by the bluntly rounded apex of each interstitial spine in the male circumdeclivital ring; by the much more acutely pointed terminal mucro; and by the other characters described below (Wood 1982:613 distinguishes *inaequalis* and *alternus* Wood).

Male: Length 1.7–1.9 mm, 2.3 times as long as wide; color dark brown. Frons not visible on type or cotype.

Antennal scape short, not flattened; club smaller than in *inaequalis*, subcircular in outline, very slightly longer than wide, sutures 1 and 2 weakly procurved, dividing club into equal thirds, sutures devoid of setae on central third of club width. Pronotum 1.1 times as long as wide; sides almost straight and parallel on more than basal half, rather broadly rounded in front, anterior margin armed by eight small serrations; anterior slope closely, rather coarsely asperate, small asperities continue half distance from summit to base; basal fourth mostly reticulate, punctures moderately coarse. Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; striae weakly impressed at base, rather strongly impressed by base of declivity, punctures deep; interstriae smooth, shining, slightly wider than striae, increasingly convex on posterior third, each ending in a projecting spine, those on even-numbered interstriae conspicuously shorter, projecting only slightly, projecting more conspicuously (equally) on odd-numbered interstriae, apex of all spines bluntly rounded. Declivity very steep, slightly convex within circumdeclivital row of spines; striae not impressed, punctures decreasing in size from base, 1 and 2 extend to base of mucro, 3–8 distinct on basal third, confused below; no tubercles immediately below major spines, 3 armed near middle by two small spines, apex of 9 bluntly projecting about one-fourth distance toward apex of mucro; mucro rather slender (about 60 degrees as seen from dorsal aspect); all surfaces shining. Vestiture restricted to declivity (including ends of spines); very short, sparse on face of declivity

Distribution: Venezuela: "Venezuela, type."

Hosts: The closely allied *inaequalis* breeds in *Acacia*, *Inga*, and similar Leguminosae.

Biology: Probably breeds in the xylem of cut, broken, or unthrifty stems about 3–10 cm in diameter.

Notes: The above treatment was based on the male holotype and 1 male cotype from Venezuela; both specimens were examined.

Hylocurus colombianus Wood, n. sp.

Hylocurus colombianus Wood: Holotype ♂; Honduras, Rio Negro, Santander Sur, Colombia; USNM, Washington, designated below

Diagnosis: Rather closely allied to *acutedentatus* Schedl. Remotely allied to *trispinatus* Schedl, except elytral declivity more strongly convex; and by the very different sculpture of the declivity, especially the deep, confused punctures.

Male: Length 2.0–2.3 mm, 2.9 times as long as wide; color dark brown, almost black. Frons broadly convex from epistoma to vertex, a small transverse carina on median fifth slightly below upper level of eyes; surface rugose-reticulate, median area on lower two-thirds with obscure, small punctures, lateral areas and above with small, subtuberculate granules; vestiture not evident; antennal scape club-shaped, with about six setae, club with middle two-thirds of suture 1 obsolete. Pronotum 1.1 times as long as wide; about as in preceding

species. Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures small, deep; interstriae very slightly wider than striae, smooth, shining on basal two-thirds of disc, punctures very small, uniseriate, on posterior fourth each with about three to four small nodules. Declivity broadly convex, steep, mucro rather long, acute; striae and interstriae with punctures confused, punctures rather small, deep; position of basal half of interstriae 3 feebly elevated, with one pointed tubercle near middle of declivity, basal third of 9 modestly elevated and terminating in a small spine. Vestiture confined to and near declivity, of rows of minute strial hair, and rows of erect, slender, interstitial setae, each seta at base of declivity about as long as distance between rows.

Female: Similar to male except nodules on and near base of declivity much smaller, some indistinct, and crest of declivital interstriae 9 not as high.

Distribution: Colombia.

Type material: The male holotype, female allotype, and 9 paratypes were taken at Honduras, Rio Negro, Santander Sur, Colombia, 19, 26-VI-1959, guamo seco, A. Benavides. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

Biology: Boring in recently cut tree seedlings.

Hylocurus acutedentatus Schedl

Hylocurus acutedentatus Schedl, 1978:300. Holotype ♂; Encruzilhada, Bahia, Brazil, 980 m; NHMW, Wien (References in Wood & Bright c1992:422)

Diagnosis: Distinguished from *colombianus* Wood by the smaller size; by the smaller nodules on the male discal interstriae near the declivity; by the much longer spine on declivital interstriae 3; and by other characters listed below.

Male: Length 2.7 mm, 2.9 times as long as wide; color dark reddish brown. Frons broadly convex, rather coarsely, closely tuberculate, a low transverse carina near middle. Antenna as in *colombianus*. Pronotum 1.1 times as long as wide, about as in *colombianus*. Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; striae rather weakly impressed, punctures strongly impressed, rather small at base, gradually increasing to three times as large at base of declivity; interstriae smooth, shining, punctures about two-thirds as large as on adjacent striae, uniseriate, replaced on posterior fourth by about three to five coarse, rounded nodules before declivity, each nodule almost as high as wide. Declivity steep, weakly convex, mucro obtuse, rather short; lateral surfaces smooth, shining, interstriae 1 strongly reticulate; striae 1 and 2 with punctures small, partly confused on lower half; 3 distinctly elevated slightly above middle and armed by one large, slender, pointed spine (twice as long as its basal width); lateral areas coarsely, deeply, closely punctured; interstriae 1 at base with a small pointed tubercle; 9 moderately elevated, ending abruptly. Vestiture restricted to and near declivity, consisting of

small strial hair and longer, erect interstitial bristles (mostly in uniseriate rows); those at base blunt, each slightly longer than distance between rows, mostly half as long on face of declivity.

Distribution: Brazil: Encruzilhada, Bahia, XI-1972, 980 m, M. Alvarenga.

Notes: The above treatment was based on the male holotype from Brazil.

Hylocurus trispinatus Schedl

Hylocurus trispinatus Schedl, 1978:301. Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:428)

Diagnosis: Male distinguished by having declivital interstriae 9 rather strongly elevated on its basal half and ending in a rather large, bluntly pointed, projecting spine; by the posterior elytral disc with interstriae each armed by four or five coarse, rounded nodules; and by other characters described below.

Male: Length 2.0–2.1 mm, 2.6 times as long as wide; color very dark brown. Frons broadly convex, surface moderately punctate-rugose, rugosities slightly below upper level of eyes forming an irregular, transverse, subcarinate row on more than median half; vestiture short, sparse, inconspicuous; antennal club subcircular, suture 1 feebly, 2 moderately procurved, middle third of suture 1 glabrous. Pronotum 1.03 times as long as wide; sculpture as in allied species. Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; striae weakly impressed, punctures rather coarse, deep; interstriae slightly wider than striae, surface on basal half of disc smooth, shining, uniseriate punctures less than half as wide as those of striae, posterior half armed by about three to five coarse, acutely rounded uniseriate nodules. Declivity very steep, broadly convex; from dorsal aspect, terminal mucro moderately, subacutely produced; basal half of interstriae 9 elevated and moderately produced into a projecting spine (ending well before level of apex of mucro); face of declivity smooth, shining, strial punctures moderately coarse, deep to strial apices; interstriae 1 with one to three small tubercles on basal third, 3 with one to three small tubercles near middle on basal half, others unarmed. Vestiture restricted to posterior half of elytra, consisting of minute strial hair and interstitial rows of rather coarse, erect bristles each slightly longer than distance between rows on posterior disc, slightly shorter and less abundant on declivity.

Distribution: Brazil: Nova Teutonia, Santa Catarina, 27°11' B, 52°23' L, XI-1963, 300–500 m, F. Plaumann; Agudos, Duraflora SA, Parana, 8-V-1984, ethanol trap in pine stand, C.A.H. Flechtmann.

Biology: Attracted to ethanol trap.

Notes: The above treatment was based on 2 males from Brazil. The Nova Teutonia male was compared by me directly to the male holotype, which is also from Nova Teutonia.

Hylocurus nodifer Wood, n. sp.

Hylocurus nodifer Wood: Holotype ♂; Cardinamarca, Finca Belle Vista near Sasaima, Colombia; USNM, Washington, designated below

Diagnosis: Distinguished from *trispinatus* Schedl by the absence of a projecting spine at the apex of interstriae 9; and by the smaller, less numerous granules or nodules on the disc at and near the margin of the declivity. It is presumed that the male and female included here are of the same species.

Male: Length 1.8–2.0 mm, 2.4 times as long as wide; color very dark brown, elytra almost black. Frons similar to *trispinatus*, except transverse carina more definite, more strongly elevated, transverse impression below carina slightly deeper; row of setae complete on suture 1 of antennal club. Pronotum 1.1 times as long as wide, about as in *trispinatus*, except anterior margin armed by 2 coarse serrations. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; disc about as in *trispinatus*, except striae not impressed, interstitial nodules restricted to posterior fourth of disc, nodules not as high, less acutely rounded, about two to four nodules on each interstriae. Declivity not as steep and more distinctly, evenly convex than in *trispinatus*; face of declivity similar to *trispinatus*, interstriae 1 with one or two small granules near base, 3 with small, indistinct nodules on upper fourth, a row of small tubercles continuing to middle of declivity length, 9 weakly elevated on basal half, armed by several tubercles of medium size. Vestiture similar to *trispinatus*, more regular and slightly more numerous on face of declivity.

Female: Similar to male except serrations on anterior margin of pronotum indefinite; striae punctures on disc smaller; not as deep, interstitial nodules reduced to rather small tubercles, declivital base less abrupt, face more strongly convex, as in male except tubercles smaller, vestiture finer (almost hairlike), longer.

Distribution: Colombia.

Type material: The male holotype and female allotype were taken at Cundinamarca, Finca Bella Vista near Sasaima, Colombia, 25-V-1965 (male), 6-VI-1965 (female), P.R. Craig. The holotype and allotype are in the U.S. National Museum, Washington.

Notes: The above treatment was based on 1 male and 1 female from the same locality in Colombia. They are probably of the same species, but confirmation is needed.

Hylocurus singularis Wood

Plate LXIII

Hylocurus singularis Wood, 1971:31. Holotype ♀; 8 km SW Bumbum, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:428)

Diagnosis: Distinguished from *villifrons* Wood by the presence of a conspicuous transverse carina on the male frons; by the female frons being ornamented by a dense brush of setae; by the presence of tubercles only

on odd-numbered declivital interstriae; and by the longer, more slender declivital setae.

Male: Length 2.0–2.4 mm, 2.9 (female 3.0) times as long as wide; color dark reddish brown. Frons broadly convex, a conspicuous transverse carina on median half slightly below upper level of eyes, surface partly rugose-reticulate, punctures below carina small, obscure, those above coarse, close, rather deep; vestiture sparse, short, moderately coarse; antennal scape almost as short as pedicel, suture 1 moderately procurved, almost attaining middle of club length. Pronotum 1.1 times as long as wide; about as in allied species, anterior margin armed by 6 serrations. Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; striae very weakly impressed, punctures rather coarse, deep (interiors of most reticulate), interstriae as wide as striae, smooth, shining, punctures uniseriate, very small (one-fourth as wide as those of striae). Declivity steep, convex; surface rugose-reticulate; all interstriae armed by uniseriate, rather small, pointed tubercles on less than basal half, tubercles continue on 1 and 3 to near apex, 9 acutely elevated and joining costal margin well before suture; base of declivity with interstriae 3 briefly, longitudinally costate, others with two to four subcostate tubercles. Vestiture of rows of stout, erect, interstitial setae, longest equal in length to distance between rows.

Female: Similar to male except frons broadly, shallowly concave from epistoma to vertex and ornamented by abundant setae of moderate, uniform length; scape more strongly flattened, with a small tuft of setae; anterior margin of pronotum unarmed by serrations; tubercles on declivity smaller, rounded, carinae absent; declivital setae more slender, slightly longer.

Distribution: Venezuela: 8 km SW Bumbum, Barinas, 11-II-1970, 150 m, No. 313, tree seedling, SLW.

Hosts: Tree seedling that resembled guava.

Biology: Boring in wood of small stems.

Notes: The above treatment was based on the type series of 29 specimens from Venezuela.

Hylocurus villifrons Wood

Plate LXIV

Hylocurus villifrons Wood, 1971:30–31. Holotype ♀; Rancho Grande, Pittier National Park, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:429)

Diagnosis: Distinguished from *singularis* Wood by the absence of a male transverse frontal carina; by the flattened, pubescent female frons; by the smooth, shining elytral declivity, with all rows of interstitial tubercles continuing to their apex.

Male: Length 2.1–2.5 mm, 2.9 (female 3.2) times as long as wide; color very dark reddish brown. Frons with upper third to vertex smooth, shining, coarsely, very closely, deeply punctured; lower two-thirds partly reticulate, a few small, shallow punctures, median area from epistoma to level of antennal insertion smooth, shining;

vestiture sparse above, moderate below; antenna similar to *singularis*. Pronotum and elytral disc as in *singularis*, base of declivity more abrupt, rows of fine tubercles extend to their apex on all interstriae; interstriae 1–6 at base of declivity each armed by one to three small tubercles, 6–8 each with a short, longitudinal carina. Declivity somewhat abrupt, very broadly convex, steep; striae weakly impressed, punctures shallow, rather obscure; interstriae feebly convex, shining, each with a row of small, rounded tubercles, 9 acutely elevated, its costa curving to join costal margin; rugose-reticulate on and near mucro. Vestiture confined to declivity, interstitial setae short, stout, moderately abundant, confused at least on 1–3, longest setae about equal in length to width of an interstriae.

Female: Similar to male except frons flat (feebly concave?), densely pubescent, longest setae on vertex extending to middle of frons; anterior margin of pronotum not serrate; base of elytral declivity rounded, tubercles smaller; setae on declivity mostly uniseriate, more slender, less numerous.

Distribution: Venezuela: Rancho Grande, Pittier National Park, Aragua, 9-VI-1970, 1100 m, No. 432 (Guttiferae), No. 409 (Meleaceae), SLW; El Laurel Experimental Farm 12 km SW Caracas, 1-V-1970, SLW; Colonia Tovar, Aragua, 4-V-1970, 1700 m, No. 499, tree branch, SLW.

Hosts: Guttiferae sp., Meleaceae sp., tree tranches.

Biology: Specimens were removed from the wood of stems 2–5 cm in diameter. The galleries were similar to other members of the genus.

Notes: The above treatment was based on the type series of 78 specimens from Venezuela.

Hylocurus woytkowskii Wood, n. sp.

Hylocurus woytkowskii Wood: Holotype ♂; Almirante, Dep. San Martin, Peru; USNM, Washington, designated below

Diagnosis: Distinguished from *spinifex* Blandford by having the antennal insertion in the usual, lateral position near the eye; by the rugose-reticulate elytral declivity; and by the very different, shorter male elytral spines.

Male: Length 2.6 mm, 2.8 times as long as wide; color dark reddish brown. Frons largely concealed on available specimen by pronotum, apparently very similar to male *villifrons* Wood; antenna as in *villifrons*. Pronotum 1.06 times as long as wide; as in *villifrons*. Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; striae weakly impressed on basal half, stronger near declivity, punctures rather small at base, almost twice as large at base of declivity, interiors of punctures reticulate near declivity; interstriae smooth, shining on basal half (punctures minute to obsolete), 2, 4, and 6 strongly costate on posterior third, ending abruptly at declivity margin in a slightly projecting, pointed spine, odd-numbered interstriae on posterior third each armed by a row of about six, pointed tubercles (not as high as costae). Declivity abrupt at base,

broadly convex, steep, entire declivity rugose-reticulate; face with stria punctures minute to obsolete, interstriae 1 and 3 each with a row of fine tubercles to base of mucro, 2, 4, 5, and 7 each with one to four similar tubercles on basal fourth. Vestiture mostly abraded or obsolete, a few short setae on face, a few slightly longer setae at basal margin of declivity.

Distribution: Peru.

Type material: The male holotype was taken at Almirante, Dep. San Martin, Peru, 12-XII 1936, 1900 m, No. 3737, subtropical forest, F. Woytkowski. The holotype is in the U.S. National Museum, Washington.

Hylocurus spinifex Blandford

Hylocurus spinifex Blandford, 1904:225. Lectotype ♂; "Mexican" [actually Brazilian] tobacco refuse intercepted at Paris; BMNH, London; designated by Wood 1982:636 (References in Wood & Bright c1992:428)

Diagnosis: The male is distinguished by the strong mesad displacement of the antennal insertions; by the size and arrangement of spines on the elytral declivity; and by other characters described below.

Male: Length 2.0 mm, 2.6 times as long as wide; color very dark reddish brown, almost black. Frons convex, antennal insertions strongly displaced dorsad (to midway between epistoma and upper level of eyes) and mesad (separated by a distance equal to less than length of scape); epistomal margin with a small, median tubercle, lower third of frons weakly convex, smooth, shining, with fine punctures, upper two-thirds very coarsely, closely, rugosely punctured; vestiture of sparse, fine, short hair; antennal club not visible on specimens at hand. Pronotum 1.0 times as long as wide; summit anterior to middle of pronotum length, anterior slope strongly declivous, asperities coarse, close; area behind summit mostly smooth, punctured. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; striae not impressed except weakly near declivity, punctures small, gradually increasing to twice as large before base of declivity; interstriae at base almost twice as wide as striae, only slightly wider than interstriae at base of declivity, surface shining, punctures small, uniseriate, rather widely spaced. Declivity truncate, circumdeclivital row of acutely pointed spines on basal margin; 1 unarmed, 2, 4, and 5 each with one moderately coarse spine, 3 with a very large, laterally compressed spine on its base, curved slightly ventrad, 7 with a coarse, pointed spine, 8 with a small spine, 9 with a coarse spine (about equal to 7), costal margin with a small spine about in line with interstriae 4, broadly, shallowly emarginate to suture between these two spines; 2 with a moderately large spine just before apex; face of declivity smooth, shining, striae 1–9 extending onto face in rows. Sparse, short setae on spines and face of declivity.

Distribution: Brazil: Labeled "Mexico tobacco," recovered from tobacco crate refuse in Paris that was thought to have originated in Mexico; however, these

species are now known to have come from Brazil (Wood 1982:399).

Notes: The above treatment was based on the male lectotype and on 1 male lectoparatype.

Hylocurus retusipennis Blandford

Hylocurus retusipennis Blandford, 1898:223. Holotype ♂; "Mexican" [actually Brazilian] tobacco refuse intercepted at Paris; BMNH, London (References in Wood & Bright c1992:427)

Hylocurus dubius Schedl, 1959:547. Lectotype ♂; Rondon, Parana, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:424). *New synonymy*

Diagnosis: Male with a circumdeclivital ring of interstitial spines of equal length, crest of 9 separated from costal margin by a narrow cleft (on striae 9); antennal club small, subcircular, sutures 1 and 2 very weakly procurved, dividing club into equal thirds; transverse frontal carina obscure (male) to obsolete (female).

Male: Length 1.9–2.1 mm, 2.8 times as long as wide; color very dark brown. Frons with a weak transverse impression from epistoma to a weak transverse crest just below upper level of eyes, broadly convex above crest, surface subreticulate and moderately punctate-granulate above crest, mostly smooth below, with small, distinct punctures; vestiture sparse, rather short above, longer toward epistoma; antennal scape short, slightly longer than pedicel, club small, subcircular; sutures 1 and 2 weakly procurved, row of setae on 1 absent on middle third. Pronotum 1.1 times as long as wide; sculpture about as in other members of this genus. Elytra 1.6 times as long as wide; 1.5 times as long as pronotum; striae weakly impressed on basal third, moderately near declivity; interstriae slightly wider than striae, weakly convex except moderately near declivity, surface smooth, shining, punctures in sparse uniseriate rows, each less than one-third as large as those of striae; discal interstriae ending in a circumdeclivital row of short, blunt spines of equal length. Declivity descending abruptly, broadly, rather weakly convex; mucro moderate, obtuse; striae 1 and 2 clearly, rather finely punctured to base of mucro, striae in lateral areas obscure, punctures coarse, deep near circumdeclivital spines, much smaller near base of mucro; middle of 1 armed by one to three small, pointed denticles, a larger denticle at junction of 3 and 5; crest of 9 moderately elevated, separated from costa. Vestiture of stout, short setae arising in a transverse row from apices of circumdeclivital spines and from middle half of declivital interstriae 1 and 3.

Female: Similar to male, except frons uniformly convex, smooth, shining, minutely (moderately close) punctured, sparsely pubescent; anterior margin of pronotum not serrate; circumdeclivital ring of spines absent, crest of 9 rather weakly elevated, armed by a crest of rounded tubercles, other small tubercles at base of declivity.

Distribution: Brazil: Rondon, Parana, 24°38' B, 50°07' L, 1950s, 500 m, F. Plaumann.

Notes: The above treatment was based on 6 males and 12 females from Brazil. Blandford's series of *retusi-*

pennis was compared to my specimens. Schedl's syntypic series of 3 males and 3 females of *dubius* was examined and compared directly to my material. Only one species is represented by this material. Schedl's (1979:85) designation of a "holotype" and an "allotype" for *dubius* Schedl was not valid under the International Code on Zoological Nomenclature. For this reason, I here designate that syntype ("holotype") as the male lectotype of *Hylocurus dubius* Schedl, as indicated above, and his "allotype" as the lectoallotype of this species.

Hylocurus elegans Eichhoff

Plate LX

Hylocurus elegans Eichhoff, 1872:134. Holotype ♂; Teapa, Tabasco, Mexico; IRSNB, Brussels (References in Wood & Bright c1992:424)

Diagnosis: Distinguished from *retusipennis* Blandford by the smaller size; by the presence of a transverse frontal carina in the male, a dense tuft of hair in the female; by the crest of declivital interstriae 9 joining the costal margin; and by other characters described below.

Male: Length 1.3–1.5 mm, 2.2 times as long as wide; color moderately dark reddish brown. Frons with a subacute transverse carina on more than median half, distinctly, transversely impressed and reticulate below carina, broadly, finely granulate-rugose above; vestiture sparse, short above, a few much longer setae near epistoma; antennal scape slender, three times as long as pedicel, club subcircular, sutures 1 and 2 almost obsolete except at margins. Pronotum 1.2 times as long as wide; similar to *retusipennis* except anterior margin more coarsely serrate. Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; striae not impressed except weakly near base of declivity, punctures deep, small on basal third, twice as large toward base of declivity; interstriae wider than striae at base, narrower at base of declivity, surface smooth, shining, punctures less than one-third as large as those of striae, each ending in a blunt spine of equal length, most spines not projecting. Declivity abrupt, very steep, broadly, moderately convex; striae 1 and 2 distinct to base of mucro, others obscure, punctures small except larger near circumdeclivital spines; interstriae 1 with three or more tubercles near middle, 2 rather strongly constricted, 3 usually with one to three small, pointed tubercles; crest of interstriae 9 acutely elevated and joining costal margin. Vestiture on and near declivity of short, stout setae on all interstriae.

Female: Similar to male except frons almost flat to vertex, area above eyes densely pubescent except narrowly glabrous on median line, setae moderately long, of almost uniform length; anterior margin of pronotum not serrate; striae punctures only slightly larger near declivity, circumdeclivital ring of spines absent; face of declivity more strongly convex, sculpture finer, setae more slender, slightly longer.

Distribution: Mexico (Nayarit to Veracruz) to Colombia.

Colombia: Caicedonia, Valle de Cauca, 20-30-V-1959, ramas secas de guamo bejuco, J. Restrepo; El Bosque at Caicedonia, Valle de Cauca, VI-1959, ramas de cafe, J.H. Lasso.

Hosts: *Acacia* sp., *Inga* sp., *Coffea arabica*, woody lianas.

Biology: Galleries were made in the wood of stems 2–5 cm in diameter. The habits and behavior resemble other species of this genus.

Notes: The above treatment was based on 12 specimens from Colombia and on more than 200 others from Mexico and Central America.

Hylocurus declivis Wood, n. sp.

Holocurus declivis Wood: Holotype ♂; Colonia Tovar, Aragua, Venezuela; USNM, Washington, designated below

Diagnosis: Male elytral declivity more uniformly convex, without a peripheral subconcave impression inside of the circumdeclivital ring; circumdeclivital ring poorly formed, not projecting, spines not pointed; antennal club conspicuously longer than wide, sutures strongly procurved, 1 attaining middle of club.

Male: Length 2.8–3.1 mm, 3.1 times as long as wide; color medium reddish brown. Frons broadly, evenly convex from epistoma to vertex; surface rugose-reticulate except near epistoma; central half with about 20 shining tubercles; vestiture short, sparse, inconspicuous; antennal scape about three times as long as pedicel, slightly flattened, ornamented by about a dozen long setae, club 1.5 times as long as wide, sutures strongly procurved, 1 extending slightly beyond middle of club. Pronotum 1.1 times as long as wide; similar to allied species; anterior margin armed by a median pair of rather large serrations and two to four small lateral serrations. Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; striae not impressed on basal half, moderately impressed at and near base of declivity, punctures rather small, moderately impressed; interstriae twice as wide as striae, surface almost smooth, shining, punctures uniseriate, small, less than half as large as those of striae. Declivity abrupt, steep, rather weakly convex; basal margin armed by a circumdeclivital ring of equal interstitial elevations (one on each interstriae), nodule (spine) moderately high, blunt, not projecting as a spine; striae 1–3 narrowly, distinctly impressed and punctured to base of mucro, 4–8 impressed and punctured only near base, 9 subacutely costate, costa joining costal margin and continuing to suture; interstriae 1 slightly elevated and armed on lower half by a row of about six small tubercles, 2–8 each with a row of small punctures; area on and near mucro rugose-reticulate. Vestiture near and on declivity consisting of interstitial setae, each seta equal in length to half distance between rows, uniseriate, except confused on 1 and near circumdeclivital ring.

Distribution: Venezuela (Aragua).

Type material: The male holotype and 2 male paratypes were taken at Colonia Tovar, Aragua, Venezuela, 4-V-1970, 1700 m, No. 487, Melastomaceae branches, SLW. The holotype and paratypes are in the U.S. National Museum, Washington.

Biology: Males were beginning entrance tunnels in cut stems 3 cm in diameter.

Hylocurus inaequidens Wood, n. sp.

Hylocurus inaequidens Wood: Holotype ♂; Telemaco Borba, Parana, Brazil; MZUSP, Sao Paulo, designated below

Diagnosis: Remotely allied to *declivis* Wood. The male is distinguished by the dark reddish brown color; by the very different arrangement of larger spines in the circumdeclivital ring; by the absence of setae on the declivity face; and by other characters described below.

Male: Length 3.0 mm, 3.0 times as long as wide; color dark reddish brown. Frons rather strongly convex eye to eye, from epistoma to vertex; surface rugose-reticulate from epistoma to vertex; rather numerous punctures replaced by shining, rounded tubercles, some punctures on peripheral areas; glabrous except for moderate epistomal brush; antennal club 1.7 times as long as wide, about 4.0 times as long as scape, outline oval, sutures 1 and 2 strongly procurved, 1 attaining slightly more than basal third, 2 about two-thirds of club length. Pronotum 1.1 times as long as wide; widest slightly behind middle of pronotum length, rather strongly arcuate on basal half, weakly constricted on anterior half, rather narrowly rounded in front; anterior margin armed at median line by a pair of moderately large serrations; summit at middle of pronotum length, anterior slope steep, rugose-reticulate to base; asperities rather small, close, confused, continued at and behind summit to base, with many transverse rugae; sparse short setae on and near anterior and lateral margins. Elytra 1.9 times as long as wide, 1.6 times as long as pronotum; disc occupying basal 67 percent of elytra length; disc smooth, brightly shining; striae not impressed, punctures moderately large, deep; interstriae as wide as striae, obscure punctures on 1 and base of 2. Declivity obliquely truncate, face moderately convex, with a circumdeclivital ring of spines at base; spines on interstriae 1, 2, 4, 6, and 8 comparatively small, tapered and acutely pointed, those on 3 very large, similarly pointed, 9 continued as a subacutely elevated costa to submucronate apex of suture; face with striae extending almost to costa, obscured in lateral areas on type, punctures small, shallow; sutural interstriae armed by 2 to 4 small tubercles, 3 sometimes with one or two minute tubercles; declivity glabrous.

Distribution: Brazil (Parana).

Type material: The male holotype (10-X-2003) and 1 male paratype (26-IX-2003) were taken at Telemaco Borba, Parana, Brazil, Klabin Papel e Celulose, ethanol baited intercept trap, *Pinus taeda* stand, C.A.H. Flechtmann. The holotype is in the Museum de Zoologia,

Universidade de Sao Paulo, Sao Paulo. The paratype is in USM, Washington.

Hylocurus aequalis Wood, n. sp.

Hylocurus aequalis Wood: Holotype ♂; Recanto Champagnat, Itaara, Rio Grande do Sul, Brazil; Museu de Zoologia, Universidade de Sao Paulo, Sao Paulo, designated below

Diagnosis: Distinguished from *declivis* Wood by the slightly smaller size; by the dark reddish brown color; by the spines in the circumdeclivital ring being distinctly larger, projecting slightly; by the finer longer setae on the face of the declivity; and by the very different male frons as described below.

Male: Length 2.3–2.6 mm, about 3.7 times as long as wide; color dark reddish brown. Frons rather strongly convex eye to eye from epistoma to vertex, surface rugose-punctate on central three-fourths, without any shining tubercles; vestiture rather coarse, moderately long, rather numerous to epistomal brush; antennal club oval, 1.2 times as long as wide, sutures 1 and 2 indicated by rows of setae, 1 almost attaining middle of club length, 2 three-fourths of club length. Pronotum 1.1 times as long as wide, widest on basal half, sides on basal half weakly arcuate, rather narrowly rounded in front; anterior margin armed by 12 rather slender serrations of moderate size; summit at middle of pronotum length; surface rugose-reticulate from anterior margin to base (including spaces between asperities); anterior slope steep, asperities rather small, close, confused; posterior areas with a moderate number of small, shining tubercles from summit to base of pronotum, punctures not evident. Elytra about 1.8 times as long as wide (elytra spread on all specimens at hand), 1.7 times as long as pronotum; disc occupying basal 75 percent of elytra length; disc almost smooth, shining, striae not impressed, punctures small, rather deep; interstriae almost twice as wide as striae, punctures minute, uniseriate. Declivity very steep, obliquely truncate, with circumdeclivital row of seven blunt spines, row 8 extending to suture below as a subacute costa; each spine on basal row of equal length, blunt, projecting moderately (conspicuously more than on *declivis*); apical mucro poorly formed; face of declivity rather weakly convex laterally, more distinctly on median area; punctures on striae 1–3 mostly in stria rows, mostly confused on lateral areas; surface between punctures mostly smooth, reticulate from suture to striae 2. Vestiture of moderately numerous slender hairlike setae of moderate length, uniformly distributed.

Distribution: Brazil (Rio Grande do Sul).

Type material: The male holotype and 2 male paratypes were taken at Recanto Champagnat, Itaara, Rio Grande do Sul, Brazil, 7-IX-1982, ethanol intercept trap in *Eucalyptus grandis* stand, T.E.F. Silva. The holotype and 1 paratype are in the Museum de Zoologia, Universidade de Sao Paulo, Sao Paulo, 1 paratype is in the U.S. National Museum, Washington.

Hylocurus dimorphus (Schedl)

Plate LIX

Hylocurus dimorphus (Schedl), 1939:724 (*Micracis*). Syntypes ♂ ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, and Plaumann Collection (Synonymy and references in Wood & Bright c1992:424)
Hylocurus acuminatus Schedl, 1950:148. Holotype ♂; Santa Catarina, Brazil; NHMW, Wien

Diagnosis: Distinguished from *declivis* Wood by the distinctly projecting spines of the circumdeclivital ring; by the concave peripheral impression just inside of the circumdeclivital ring; and by the very unique female antenna.

Male: Length 2.4–2.8 mm, 3.0 times as long as wide; color very dark reddish brown. Frons broadly convex, upper two-thirds rather coarsely punctate-subrugose, lower third more finely sculptured; vestiture of sparse, short, rather stout setae, longer on epistoma; antennal scape short (twice as long as pedicel), not flattened; club 1.2 times as long as wide, sutures strongly procurved, suture 1 attaining middle of club. Pronotum 1.14 times as long as wide; similar to allied species; anterior margin armed by eight serrations. Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; striae not impressed except moderately between spines at margin of declivity, punctures rather small, moderately impressed; interstriae slightly less than twice as wide as striae, almost smooth, shining, punctures uniseriate, each almost half as wide as those of striae; interstriae 1–8 each ending in a large, blunt, moderately projecting spine. Declivity abrupt, very steep; central half convex, peripheral third moderately concave; interstriae 9 subacutely costate, joining costal margin and continuing to suture; interstriae 1 and 2 rugose-reticulate on lower two-thirds, striae indicated on peripheral third, confused or obsolete elsewhere; interstriae 1 and 2 armed by a row of fine granules on middle half. Vestiture of rows of fine, short stria hair and longer interstitial setae, plus a row of similar setae on circumdeclivital spines.

Female: Similar to male except frons subconcave from epistoma to vertex, densely, minutely punctured, a subacute transverse carina on vertex; antennal scape flattened, dorsal apical angle extended, with 1 reddish and 2 yellow tufts of long hair; anterior margin of pronotum unarmed; circumdeclivital ring absent, base of declivity rounded, face convex, all striae normal; interstriae rugose-reticulate, each with a row of fine, rounded tubercles.

Distribution: Brazil: Rondon, Parana, 1950s, 500 m, 24°38'B, 54°07'L, F. Plaumann; Nova Teutonia, Santa Catarina, II-1937, F. Plaumann.

Notes: The above treatment was based on 1 male paratype and 1 female paratype and on 6 male and 6 female other specimens, all from Brazil.

Hylocurus flagellatus Wood

Plate LXI

Hylocurus flagellatus Wood, 1971:32. Holotype ♀; Rancho Grande, Pittier National Park, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:425)

Diagnosis: Distinguished from *dimorphus* (Schedl) by the abundant scalelike setae on the elytral declivity; by the radically different female frons and antennal scape; and by the emarginate anterior margin of the female pronotum.

Male: Length 1.9–2.5 mm, 2.8 (female 3.3) times as long as wide; color very dark reddish brown. Frons broadly convex and rugose-reticulate above level of antennal insertion, a moderate transverse impression between epistoma and level of antennal insertion, more finely sculptured in impressed area; antenna as in male *dimorphus*. Pronotum 1.06 times as long as wide; about as in *dimorphus*. Elytra 1.8 times as long as wide, 1.5 times as long as pronotum; striae not impressed except moderately at base of declivity, punctures small, moderately deep; interstriae very slightly wider than striae, surface smooth, uneven in most specimens, obscurely reticulate in one male, punctures small, obscure; interstriae ending at base of declivity in a circumdeclivital ring of spines of equal length, each forming a blunt, weakly projecting spine. Declivital margin abrupt, face very steep, costa of interstriae 9 meeting costal margin at level of interstriae 1; face almost flat except slightly elevated toward suture on lower two-thirds; striae not visible except at base; surface rather densely covered by numerous, confused, white scales, each scale flattened, about one and one-half to two times as long as wide. Vestiture on elytral disc mostly abraded, consisting of sparse, uniseriate rows of erect, short interstitial setae.

Female: Remotely resembling male, body much more slender; frons deeply concave on more than median half from epistoma to vertex, concavity reticulate, setae of sparse, short recumbent hair except vertex bearing a large, long, projecting, penicellate tuft (capable of attaining level of antennal insertions); scape twice as long as pedicel, very broadly flattened (wider than long), bearing a large tuft of rather long, yellow hair on dorsal half, ventral half bearing two slender reddish tufts, anterior one consisting of about two to four curved setae twice as long as club, posterior tuft consisting of more than six similar exceedingly long setae extending beyond base of pronotum; club about as in *dimorphus*; pronotum 1.25 times as long as wide, anterior margin not serrate, shallowly emarginate on median one-sixth (to accommodate tuft of setae on vertex); circumdeclivital row of spines absent, base of declivity rounded, declivity more distinctly convex; declivital scales slightly less abundant, some setae at base of declivity slender; interstriae 9 not curved to meet costal margin.

Distribution: Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 431, *Nectandra*, SLW.

Biology: Boring in the wood of dying branches 2–4 cm in diameter.

Notes: The above treatment was based on the type series of 3 males and 5 females from Venezuela.

GENUS *MICRACISELLA* BLACKMAN

Micracisella blackman, 1928:192. Type-species: *Micracis opacicollis* LeConte, automatic, replacement name (Synonymy and references in Wood & Bright c1992:429)

Pseudomicracis Blackman, 1920:20. Type-species: *Micracis opacicollis* LeConte, original designation, preoccupied by Eggers 1920

Diagnosis: Distinguished from *Micracis* by the shallowly emarginate, more elongate eye; by the less strongly flattened protibia, with at least 1–5 apical denticles on the lateral margin; by the less strongly expanded antennal scape, the club wider and sutures more broadly procurved; and by the monogynous and myelophagous habits.

Description: Small species 1.2–2.5 mm, 2.8–3.2 times as long as wide; frons sexually dimorphic, female convex to shallowly concave, male less strongly impressed; eye shallowly emarginate; scape not flattened, usually ornamented by hair, club broadly oval; elytra elongate, rather weakly striate; protibiae moderately flattened, apical margin ornamented by 5-socketed denticles, at least 1 of these on lateral margin.

Distribution: Wood & Bright (c1992:429–431) list 20 species from North and Central America. One of these species also occurs in Colombia.

Micracisella nigra Wood

Micracisella nigra Wood, 1956:232. Holotype ♀; La Ceiba, Atlantida, Honduras; USNM, Washington (References in Wood & Bright c1992:430)

Diagnosis: Distinguished by the generic characters given above. Allied to *nigrella* Wood (Honduras), distinguished by the convex frons in both sexes that is impunctate and glabrous except near eyes; by the more coarsely faceted eyes, the eyes separated above by less than 1.5 times the width of an eye.

Male: Length 1.5–1.7 mm (1.3–1.5 mm in Guatemala), 2.8 times as long as wide; color black. Frons convex, median third on lower half feebly impressed, a slight transverse crest indicated at middle of area below upper level of eyes; surface very finely rugose-reticulate except almost smooth in impressed area; vestiture sparse, short, of stout setae mostly on epistoma and lateral areas; scape twice as long as pedicel, cylindrical, club subcircular; sutures 1 and 2 moderately procurved, clearly marked by rows of setae, 1 almost attaining middle of club. Pronotum 1.05 times as long as wide; summit at middle, anterior slope rather finely asperate, anterior margin armed by four to six small serrations, posterior area finely reticulate, punctures minute to obsolete, vestiture minute, obscure, mostly in asperate area. Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures minute; interstriae subreticulate, more than twice as wide as striae, punctures minute to obsolete, mostly on posterior half of disc. Declivity convex, steep; striae slightly impressed, punctures minute; interstriae each with a row of small, rounded granules; mucro weakly indicated, almost obsolete. Vestiture mostly on and near declivity, consisting of interstitial rows of erect, white scales, each scale about three times as long as wide and slightly shorter than distance between rows; setae on interstriae 1 and 2 sometimes extending to middle of disc.

Female: Similar to male except frons uniformly, more strongly convex, smooth; scape slightly flattened, bearing a small tuft of long hair; anterior margin of pronotum armed by two to four small serrations; declivity with small areas rugose-reticulate near mucro.

Distribution: Mexico (Campeche) and Honduras to Colombia.

Colombia: El Bosque, Caicedonia, Valle de Cauca, 19-VII-1959, guamo verde, J. Restrepo.

Hosts: *Lonchocarpus castillo* (in Campeche, Mexico); guamo verde (in Colombia).

Biology: Boring in the pith of very small stems; the species is monogynous.

Notes: The above treatment was based on 13 specimens from Mexico and Central America and 5 from Colombia.

GENUS *MICRACIS* LeCONTE

Micracis LeConte, 1868:164. Type-species: *Micracis suturalis* LeConte, subsequent designation by Hopkins 1914:125 (References in Wood & Bright c1992:431–434)

Diagnosis: Distinguished from *Micracisella* by the much more broadly flattened protibia, with all 5-socketed

denticles on the apical margin; by the more elongate antennal club, with the sutures much more strongly procurved; and by the more broadly oval eye, with the anterior margin entire.

Description: Length 1.6–3.8 mm, female very slightly larger than male; male 2.6–3.0, female 3.0–3.5 times as long as wide; color yellowish brown to dark reddish brown. Frons dimorphic, male convex, female broadly impressed and shallowly to strongly concave from epistoma to vertex, sculpture conservative. Eye entire, elongate-oval. Antennal scape rather short, flattened at least in female; club elongate-oval, sutures 1 and 2 strongly flattened. Pronotum longer than wide, summit anterior to middle, anterior slope asperate, anterior margin serrate. Elytra with striae weakly impressed, sculpture conservative in South American species.

Distribution: Wood & Bright (c1992:431–434) record 25 species, 19 from North and Central America, 1 from Cuba, and 5 from South America.

Biology: The species are bigynous and xylophagous. They usually infest unthrifty, injured, or broken branches less than 5 cm in diameter. At least 2 tropical species were taken from the lower bole of standing trees of moderate size (30–50 cm in diameter).

Key to the Species of *Micracis*

- 1. Antennal scape wider than long in both sexes; frons more broadly, much more strongly impressed, extending from epistoma to middle of frons in male, to upper level of eyes in female; male declivity with basal margin rounded, never rugose reticulate; elytral setae slender, in uniseriate stria and interstria rows on disc, longer, more abundant, mostly confused on declivity; Venezuela (Merida); 1.4–2.0 mm ***exilis* Wood**
- Antennal scape longer than wide in both sexes; frons convex, a few species with a weak, transverse impression on lower fourth; elytral declivity much steeper, more broadly convex, obliquely truncate in some species; larger species **2**
- 2(1). Male declivital interstriae 1, 3, 5, 7, and 9 each armed by two or more moderately coarse tubercles, those on 1 and 3 extend below middle, 9 ends almost at 3, those on 2, 4, 6, and 8 with smaller tubercles at and anterior to base; declivital surface rugose reticulate; interstria setae uniseriate, rather slender (each at least eight times as long as wide); Venezuela (Caracas); 2.3 mm ***sentus* Wood**
- Male declivity descending rather abruptly at base, interstriae 1–7 about equal, sometimes forming a circumdeclivital ring of tubercles in male; declivital setae often shorter, stouter, at least in male **3**
- 3(2). A very small species; surface of elytra shining; declivity in both sexes steep, convex; female interstriae 1–7 with rows of small tubercles, female without a circumdeclivital ring of spines; in either sex; male interstriae 1–7 about as in female; Brazil (Parana); 1.4–1.6 mm ***minulus* Wood**
- Larger species; body much more slender; male declivity with a weak or strongly developed circumdeclivital ring of tubercles **4**
- 4(3). Surfaces of elytral declivity smooth, shining; area within circumdeclivital ring more strongly flattened, tubercles on interstriae 1 rather coarse, extending almost to base of mucro; stuture 1 on antennal club extending slightly beyond middle (male) or well beyond middle (female); body color very dark brown; male frons with a moderate median tubercle at level of antennal insertion; Venezuela (Merida); tree seedling; 3.3–3.8 mm ***vitulus* Wood**

- Surfaces of elytral declivity dull, rugose-reticulate; circumdeclivital ring of tubercles at base of declivity poorly formed, area within ring much more strongly convex, tubercles on interstriae 1 small to obsolete; male frons armed by a coarse median tubercle slightly below middle of frons; body color rather reddish brown; Colombia (La Palma); cut branches; 2.5–2.6 mm
 *tropicus* Wood

Micracis exilis Wood

Micracis exilis Wood, 1971:27. Holotype ♀; 9 km S Barrancas, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:432)

Diagnosis: Scape wider than long in both sexes; frons more strongly impressed than in other South American species; basal margin of male declivity rounded (not at all truncate).

Male: Length 1.4–2.0 mm, 2.9 (female 3.1) times as long as wide; color yellowish brown, vestiture pale. Frons broadly convex from upper third of area below upper level of eyes to vertex, surface rugose-reticulate, with rather numerous fine granules uniformly distributed; lower two-thirds moderately, transversely impressed, surface subreticulate (slightly rugose); vestiture coarse, moderately abundant, uniformly distributed, moderately long; scape flattened, as wide as long, twice as long as pedicel, with a small brush of hair; club 1.1 times as long as wide, sutures 1 and 2 strongly procurved, marked by rows of setae, 1 not attaining middle of club length. Pronotum 1.15 times as long as wide; summit slightly anterior to middle, anterior slope rather coarsely asperate, anterior margin armed by six to eight rather coarse serrations, posterior area reticulate, small, sparse granules behind summit almost to basal margin; vestiture short, sparse. Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures very small, weakly impressed; interstriae about four times as wide as striae, shining, almost smooth, punctures very small. Declivity steep, broadly convex; surface much as on disc except interstriae with a few small, rounded granules. Vestiture largely confined to declivity, consisting of very small strial hair and larger, suberect, slender interstitial setae of moderate length.

Female: Similar to male except more slender; frons transversely impressed, shallowly concave from epistoma to upper level of eyes, ornamented by long hair; scape triangularly expanded, wider than long, ornamented by long hair; anterior margin of pronotum unarmed; elytral vestiture slightly shorter, less abundant.

Distribution: Venezuela: 20 km SW El Vigia, Merida, 10-XII-1969, 50 m, No. 186, tree twigs, SLW; 9 km S Barrancas, Barinas, 2-XII-1969, 150 m, No. 163, Espinito de Sabana, SLW.

Biology: Boring in wood of small branches of shrub; galleries resemble those of other members of this genus.

Notes: The above treatment was based on the type series of 9 males and 4 females from Venezuela.

Micracis sentus Wood

Plate LXV

Micracis sentus Wood, 1971:28. Holotype ♀; El Laurel Experimental Farm 12 km SW Caracas, Venezuela; USNM, Washington (References in Wood & Bright c1992:433)

Diagnosis: Male elytral declivity subtruncate, odd-numbered interstriae each armed by two or more coarse tubercles, those on 1 and 3 extend below middle of declivity.

Male: Length 2.3 mm, 2.7 times as long as wide; color reddish brown. Frons broadly convex from epistoma to vertex, surface rugose, a moderately large median tubercle at level of antennal insertions; vestiture sparse, inconspicuous, abraded; scape cylindrical, club oval, somewhat resembling *exilis* Wood. Pronotum 1.03 times as long as wide; resembling male *exilis* except more coarsely sculptured, anterior margin armed by 10 coarse serrations. Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; striae not impressed except moderately at base of declivity, punctures moderately large, deep; interstriae slightly wider than striae, surface smooth, shining, punctures small, shallow, becoming tuberculate toward base of declivity. Base of declivity rounded, face broadly convex; at base interstriae 1, 3, 5, and 7 each armed by a row of three coarse, pointed tubercles, 2, 4, and 6 each with two slightly smaller tubercles; face reticulate-granulate, 2 and 4 unarmed, 1 and 3 each with two or three smaller tubercles on lower half, 9 weakly elevated on basal half, its crest with three small tubercles. Vestiture of rows of minute strial hair; and rows of erect interstitial scales from middle of disc to base of declivity, each scale almost as long as distance between rows, about four to six times as long as wide, face of declivity with a short bristle at each tubercle.

Distribution: Venezuela: El Laurel Experimental Farm 12 km SW Caracas, Aragua, 1-V 1970, 1300 m, No. 460, tree limb, SLW.

Biology: One male just beginning to bore into the wood.

Notes: The above treatment was based on 1 male from Venezuela.

Micracis vitulus Wood

Plates LXV, LXVI

Micracis vitulus Wood, 1971:27. Holotype ♀; La Carbonera Experimental Forest 50 km NW Merida, Merida, Venezuela; USNM, Washington (References in Wood & Bright c1992:434)

Diagnosis: Male declivity with a circumdeclivital ring of interstitial spines of equal length; surface of declivity smooth, shining.

Male: Length 3.2–3.8 mm, 3.2 (female 3.6) times as long as wide; color very dark reddish brown. Frons broadly convex above, shallowly, transversely impressed from epistoma to level of antennal insertions; surface rugose-reticulate, with a few granules above, finer below; antenna resembling *sentus* Wood. Pronotum 1.1 times as long as wide; resembling *sentus*, except more finely sculptured. Elytra 2.1 times as long as wide, 1.9 times as long as pronotum; striae not impressed, except weakly near base of declivity, punctures rather deep, small on basal half, slightly larger near base of declivity; interstriae narrower than striae, smooth, shining, punctures minute to obsolete; each discal interstriae ending in a short, blunt spine, those on 1 and 2 not projecting, 3–5 projecting slightly. Base of declivity abrupt, with a circumdeclivital ring of spines; very steep, very broadly convex; striae impressed, punctures coarse, deep; surfaces shining, interstriae 1 elevated on lower half, with a row of fine tubercles, 3 with similar tubercles, others irregular, not clearly tuberculate. Vestiture of stout hair on declivity, a confused row on suture of face and on circumdeclivital ring, uniseriate on other interstriae of face.

Female: Similar to male except frons broadly convex, smooth; antennal scape slightly flattened, ornamented by a large tuft of hair; sutures of antennal club more strongly procurved; circumdeclivital ring very weakly indicated, face similar to male.

Distribution: Venezuela: La Carbonera Experimental Forest 50 km NW Merida, Merida, 10 XI-1969, 2500 m, No. 128, tree seedling, SLW.

Biology: Boring in the wood of a stem 2–5 cm in diameter, in galleries typical of this genus.

Notes: The above treatment was based on the type series of 15 specimens from Venezuela.

Micracis minimus Wood, n. sp.

Micracis minimus Wood: Holotype ♀; Telemaco Borba, Parana, Brazil; MZUSP, Sao Paulo, designated below

Diagnosis: Distinguished from other South American members of this genus by the small body size; by the simple declivity in both sexes; and by other characters described below.

Male: Length 1.3 mm, about 2.2 times as long as wide (female 1.4–1.6 mm, 2.5 times as long as wide); color yellowish brown. Frons moderately convex; surface rugose-reticulate, a very small, obscure puncture on or near upper third; vestiture very sparse, mostly abraded, epistomal fringe moderately abundant; antennal scape twice as long as on female; club oval, slightly longer than wide, smooth, shining, with a peripheral fringe of minute setae, sutures not evident. Pronotum 0.90 times as long as wide; widest at base, sides on basal half weakly arcuate and converging slightly, narrowly rounded in front; anterior margin with six low, obscure serrations; summit at middle of pronotum length; anterior slope steep, asperities rather coarse, close, confused, small subasperate rugosities continuing to base on median area;

moderately numerous stout setae on asperate area, scales intermixed with very short, slender setae behind. Elytra about 1.3 times as long as wide (spread on allotype); disc occupying about 75 percent of elytra length; moderately mucronate at suture apex; disc with striae not impressed, punctures small at base, slightly larger toward base of declivity; interstriae smooth, brightly shining, about as wide as striae, punctures small, uniseriate, about one-third as large as those of striae. Declivity very steep, broadly convex; striae 1–3 about as on disc except punctures slightly smaller; lateral striae in normal pattern; sutural interstriae very narrow, 2 and 3 slightly wider, 2 and 3 each with a row of closely spaced tubercles from base to apex, 4–8 with similar tubercles; no indication of circumdeclivital spines; ventrolateral crest subacutely elevated from mucro to interstriae 8. Vestiture of minute strial hairlike setae; interstitial scales in rows on disc and on declivital interstriae 1 and 2, on 3–7 with scales on upper areas only, replaced by minute hairlike setae on lower half.

Female: Frons similar to male except more strongly convex; antennal scape half as long, with a small tuft of hair, club large, obovate, sutures 1 and 2 clearly marked by rows of setae, very strongly procurved, 1 almost attaining middle of club length, 2 about three-fourths of club length. Pronotum resembling male except posterior areas not rugose, densely micropunctate; elytral disc similar to male, strial punctures slightly larger. Declivity more narrowly convex than on male, strial punctures smaller, not as deep, interstitial tubercles more slender, pointed, not as widely but more regularly placed and extending to apex on all interstriae; ventrolateral crest rounded, not elevated.

Distribution: Brazil (Parana).

Type material: The female holotype (7-IX-2000), male allotype (22-XI-1999), and 3 female paratypes (10-XI-2000, 19-X-2001, 15-III-2003) were taken at Telemaco Borba, Parana, Brazil, Klabin Papel e Cellulose forest from ethanol baited funnel traps in a *Pinus taeda* stand, C.A.H. Flechtmann. One female paratype is from UFRRJ campus, Scropedica, Rio de Janeiro, Brazil, 14 XII-2000, ethanol baited funnel trap in *Pinus* sp. stand, A.M. Lunz, 1 paratype is from the same locality, 3-VIII-2000, ethanol trap in Atlantic forest, A.M. Lunz, and 4 paratypes are from the same locality, 3-VIII-2000, 17-V-2001, *Mimosa caesalpiniaefolia* stand, ethanol trap, A.M. Lunz.

Micracis tropicus Wood, n. sp.

Micracis tropicus Wood: Holotype ♂; Manilla, La Palma, Cundin, Colombia; USNM, Washington, designated below

Diagnosis: Male declivity with a circumdeclivital ring of spines of equal length, very poorly formed; surface of declivity rugose-reticulate (dull).

Male: Length 2.5–2.6 mm, 2.8 times as long as wide; color reddish brown. Frons broadly convex on slightly more than upper half of area below upper level of eyes, surface rugose-reticulate and with moderately abundant,

shining, rounded tubercles of varying size, a larger median tubercle at lower margin of convex area; lower third moderately, transversely impressed, surface sub-reticulate; vestiture sparse, apparently abraded; antennal scape elongate, slightly flattened, club conspicuously longer than wide, sutures 1 and 2 strongly procurved, 1 attaining middle of club length. Pronotum 1.0 times as long as wide; summit at middle, anterior slope rather coarsely asperate, anterior margin armed by 10 rather coarse serrations; posterior areas reticulate, a few fine tubercles behind summit, punctures obsolete. Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures small, distinct; interstriae about three times as wide as striae, almost smooth, shining on basal half, minutely reticulate-granulate behind, punctures small, sparse; margin of declivity somewhat abrupt, each interstriae weakly elevated, representing a weak circumdeclivital spine (not projecting) or weak prominence of equal length. Declivity broadly convex, steep; mucro moderate; striae weakly impressed, punctures obscure; interstriae 1 and 3 weakly elevated, 3 with about three small tubercles, surface reticulate-

granulate, dull. Vestiture restricted to declivity, of small, erect pale scales, confused except uniseriate on 2 and 3.

Female: Similar to male except frons very broadly convex, a weak, median impression on middle third, surface very finely rugose-reticulate, without granules, vestiture restricted to epistomal area; scape as in male, except abundant long hair radiating in all directions; pronotum more finely sculptured; anterior margin not serrate; elytral interstriae shining to near base of declivity, declivital base rounded, without circumdeclivital ring of weak elevations; declivity more strongly convex, vestiture more slender, less abundant, extending to posterior third of disc.

Distribution: Colombia.

Type material: The male holotype, female allotype, and 1 paratype were taken at Manilla, La Palma, Cundin, Colombia, 25-IV-1959, gumo rama seca, Alvaro Diaz; 1 paratype is from La Laguna, Coromoro, Santander Sur, 26-VI-1959, guamo seco, A. Benevides. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington.

TRIBE CARPHODICTICINI

Description: Frons weakly to moderately dimorphic, male strongly convex, female weakly to moderately flattened, occasionally pubescent; eye elongate, sinuate to shallowly emarginate in South American genera; scape short to elongate, funicle 5-segmented, club small, flattened, symmetrical to rather large and asymmetrical with oblique sutures marked by grooves and rows of setae, not septate; pronotum elongate, sides conspicuously constricted on middle half, entirely unarmed by

asperities; posterior face of head truncate, dorsomedian area not extended caudad; procoxae narrowly to moderately separated; protibia stout to rather slender, armed by socketed denticles on lateral margin; scutellum visible; basal margins of elytra either rounded or moderately elevated and acutely costate.

Biology: Only *Carphodicticus cristatus* Wood has been observed in nature (see below). It is phloeophagous and monogynous.

Key to the Genera of Carphodicticini

- 1. Basal margins of elytra rounded, not elevated; antennal club rather large, distinctly asymmetrical, sutures slightly oblique; procoxae more narrowly separated; protibia short (only slightly longer than antennal club), stout (almost half as wide as long); phloeophagous; Venezuela; 2.0-2.4 mm ***Carphodicticus***
- Basal margins of elytra rather strongly elevated and acutely costate on a continuous, transverse line; antennal club rather small, symmetrical, sutures transverse; procoxae much more widely separated; protibia longer, much more slender; habits unknown; Argentina; 2.0 mm ***Dendrodicticus***

GENUS *CARPHODICTICUS* WOOD

Carphodicticus Wood, 1971:19. Type-species: *Carphodicticus cristatus* Wood, original designation (References in Wood & Bright c1992:437)

Diagnosis: Distinguished from *Dendrodicticus* by the larger, asymmetrical antennal club, with distinctly oblique sutures; by the rounded basal margins of the elytra; and by the more narrowly separated procoxae.

Carphodicticus cristatus Wood

Plate LXVI

Carphodicticus cristatus Wood, 1971:19. Holotype ♂; 8 km W Bumbum, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:437)

Diagnosis: See the tribal and generic characters above, especially the strong lateral constriction on the basal half of the pronotum and total absence of a pronotal declivity or asperities.

Male: Length 2.0–2.4 mm, 3.5 times as long as wide; color reddish brown. Frons very broad (frontal rectangle 1.6 times as wide as long), broadly, strongly, evenly convex from epistoma to vertex from eye to eye; epistomal margin distinctly elevated and carinate on median two-thirds; surface smooth, brightly shining, closely, moderately, deeply punctured from epistoma to vertex; glabrous except 0–12 hairlike setae above epistomal margin, a rather broad, dense epistomal brush below carina; eye broadly, moderately emarginate, coarsely faceted; antennal scape elongate, funicle 5-segmented, club moderately large, flattened, sutures 1 and 2 feebly procurved, weakly oblique. Pronotum 1.5 times as long as wide; sides rather strongly constricted on slightly more than posterior half, not declivous anteriorly; surface smooth, shining, punctures rather coarse, close, deep; glabrous; procoxae narrowly separated by a distance equal to less than one-fourth width of a procoxa. Scutellum small, flush with elytral surface. Protibia short, stout, armed by four socketed denticles. Elytra 2.0 times as long as wide, 1.5 times as long as pronotum; basal margins abrupt, not elevated or costate; striae not impressed, punctures coarse, deep; interstriae half to one-third as wide as striae, smooth, shining, punctures very minute, shallow, uniseriate. Declivity occupying about 15 percent of elytra length, very steep, base rounded, lower two-thirds broadly sulcate; interstriae 2 moderately impressed, strongly constricted, ending before apex by costa of 3; 1 slightly elevated, smooth, shining, minute punctures as on disc; 3 moderately elevated on basal third, strongly, subacutely elevated below, curving toward sutural apex below but obsolete at 2 before attaining costal margin. Vestiture confined to declivity, consisting of rather sparse, long, coarse, interstitial hair.

Female: Similar to male except frons slightly less strongly convex, setae above epistomal carina much more numerous and widely distributed; declivital costa on interstriae 3 not quite as high; declivital setae finer.

Distribution: Venezuela: 8 km SW Bumbum, Barinas, 11-II-1970, No. 326, large limb, SLW.

Hosts: Possibly *Pseudoolmedia* sp. or a rare Lauraceae.

Biology: Specimens were removed from a limb 20 cm in diameter that had been left fully exposed to the sun at least 50 days. The specimens entered the bark through entrance tunnels made by a small *Phloeotribus* species in tissue that was unusually hot. In the cambium area pairs of specimens constructed a simple branching tunnel, then other pairs branched from this branch. Hundreds of branching and rebranching gallery systems were present, 1 pair working at the apex of each branch. Larvae were in the phloem.

Notes: The above treatment was based on the type series of 103 specimens.

GENUS *DENDRODICTICUS* SCHEDL

Dendrodicticus Schedl, 1958:37. Type-species: *Dendrodicticus argentinae* Schedl, monobasic (References in Wood & Bright c1992:437)

Diagnosis: Distinguished from *Carphodicticus* by the smaller, symmetrical antennal club, with the sutures transverse; by the strongly elevated, acutely costate basal margins of the elytra; and by the much more widely separated procoxae.

Dendrodicticus argentinae Schedl

Dendrodicticus argentinae Schedl, 1958:37. Holotype, sex?; Tigre, Buenos Aires, Argentina; NHMW, Wien (References in Wood & Bright c1992:437)

Female: Length 2.0 mm, 2.6 times as long as wide (Schedl 1958:37); color reddish brown. Frons resembling *C. cristatus* Wood. Antennal club more slender than *C. cristatus*, symmetrical, sutures 1 and 2 transverse, aseptate. Pronotum 1.1 times as long as wide; apparently similar to *C. cristatus* except procoxae much more widely separated. Elytra 1.9 times as long as wide (Schedl 1958:37), their basal margin strongly elevated and acutely costate. (Schedl described this costa as finely dentate. I did not record the presence of dentations on this costa.) Disc and declivity similar to *C. cristatus* except costa on declivital interstriae 3 not as high and punctures on striae 1 and 2 much smaller. Protibia longer, more slender, and with a different arrangement of socketed denticles.

Distribution: Argentina: Tigre, Buenos Aires, I-1951, M.J. Viana.

Notes: The above treatment was based on notes made by me in 1979 on the Schedl syntype that is now in NHMW, Wien. Several attempts to locate those in the collection of the late M.J. Viana were not successful. Schedl (1975:42) placed *Carphodicticus* in synonymy under *Dendrodicticus* Schedl; however, in spite of superficial similarity, I suggest that the differences in antennal clubs, procoxae, protibiae, and the basal margin of the elytra are sufficient to delay synonymy until additional intermediate species are found. These characters as presently known are of sufficient magnitude to justify the recognition of 2 genera if no additional species are found.

TRIBE IPINI

Description: Frons usually dimorphic, male convex, female variously excavated, protuberant, or ornamented by setae; eye sinuate on anterior margin, very finely faceted in some genera, coarsely in others; antennal scape slender, elongate, funicle 5-segmented, club varying from obliquely truncate to flattened, with sutures strongly apically displaced on posterior face. Pronotum with anterior slope rather strongly declivous and closely asperate on anterior half; procoxae contiguous, intercoxal piece deeply notched or absent; protibia armed by three or four socketed teeth (sometimes a sexual difference). Scutellum visible, flush with surface of elytra. Elytral declivity moderately sulcate to deeply excavated, lateral margins of declivity often armed by tubercles or spines. Vestiture hairlike.

Biology: All are phloeophagous. They may be either monogynous or polygynous, the males are diploid. Hosts include members of the Pinaceae, although *Dendrochilus* and most *Acanthotomicus* breed in various angiosperm trees and lianas. Eggs are always deposited in niches, usually 1 egg in each niche, although some genera include species that place 2 or more eggs in a niche. Larval

mines are individual and rarely cross one another. These mines are usually exposed on the inner surface of peeled bark. The life cycle is comparatively short, with 2 or more generation`s commonly produced each year.

Taxonomy: Except for *Acanthotomicus*, which contains several species endemic to South America, the remaining genera of Ipini are represented there only by species introduced into the extensive plantations of *Pinus* species. Because our current concept of some genera in the world fauna has changed since publication of the world revision of genera (Wood 1986:67-70), the latter part of the world key to genera for this tribe is radically revised and was included here. Of these 6 genera, *Acanthotomicus* contains species endemic to South America, *Orthotomicus* and (possibly) *Ips* contain only introduced breeding populations in South American *Pinus* plantations, and *Pityogenes* is now represented in the USA and the Antillies Islands and should reach South America in the near future. The 2 remaining genera in the world fauna are not expected to reach South America.

World Key to the Genera of Ipini
(Modified from Wood 1986:68)

- 1. Elytral declivity rather narrowly bisulcate, lateral margins rather broadly elevated, rounded, and armed by not more than 3 pair of enlarged denticles; lower margin of elytral declivity rounded; prosternal intercoxal piece short, obtuse; female frons sometimes deeply, rather narrowly excavated; antennal club compressed, 2 sutures visible on apical third of posterior face; North America, Europe, Asia, N Africa; Pinaceae 1.8-3.7 mm *Pityogenes*
- Elytral declivity broadly, rather deeply excavated, margins acutely elevated and armed by 3 or more pair of denticles (1-6 pair in tropical *Acanthotomicus*); lower margin of declivity with an acutely elevated, transverse ridge separating declivital excavation from apical margin 2
- 2(1). Eye large, coarsely faceted, 2.2-4.0 times as long as wide, area below emargination at least as wide and as large (in area) as area above emargination; antennal club varying from clearly marked by procurved sutures to minutely pilose and entirely devoid of sutures; circumtropical; in Angiospermae (2 in Pinaceae in Asia); 1.4-2.7 mm *Acanthotomicus*
- Eye rather small, very finely faceted, 1.4-2.5 times as long as wide, area below emargination conspicuously reduced in area and width (to about two-thirds or less); antennal club with sutures marked by setae; north temperate (or introduced elsewhere); Gymnospermae; mostly larger species 3
- 3(2). Antennal club with sutures either weakly to rather strongly recurved (often subtruncate) or weakly to very strongly procurved; declivity usually steeper, sexual dimorphism more pronounced, lateral margins armed by 3 or fewer pair of spines in female (some males with 4 pair of spines); ventrolateral margin of declivity commonly wavy or undulating, less strongly elevated; endemic to northern hemisphere (introduced elsewhere); Pinaceae; 2.2-5.0 mm *Orthotomicus*

- Antennal club with sutures on anterior face bisinuate to acutely angulate at middle; elytral declivity more gradual, ventrolateral margin more strongly, acutely, uniformly elevated (crest not undulating or wavy), lateral margin armed by 4–6 denticles in both sexes; sexual dimorphism usually less conspicuous; endemic to northern hemisphere (introduced elsewhere); Pinaceae; 2.1–6.9 mm

Ips

GENUS *PITYOGENES* BEDEL

Pityogenes Bedel, 1888:397–398. Type-species: *Dermestes chalcographus* Linnaeus, original designation (Synonymy and references in Wood & Bright c1992:438)
Eggersia Lebedev, 1926:121. Type-species: *Bostrichus bidentatus* Herbst, subsequent designation by Wood 1986:68
Pityocera Balachowsky, 1947:44. Type-species: *Bostrichus quadridens* Hartig, original designation

Wood & Bright (c1992:438–459) list 14 species of *Pityogenes* from Europe and Asia, and 7 from North America. All breed in Pinaceae (mostly Pinus) and are of comparatively minor economic importance. One species, *chalcographus* (Linnaeus), has been transported through commerce and has been intercepted at numerous ports. It was introduced to Jamaica and has a breeding population there (Antilles Islands). Because of its past history, it should be watched very closely as a potential threat to South American *Pinus* plantations. It breeds mostly in the phloem of pine slash.

GENUS *ACANTHOTOMICUS* BLANDFORD

Acanthotomicus Blandford, 1894:89. Type-species: *Acanthotomicus spinosus* Blandford, monobasic (Synonymy and references in Wood & Bright c1992:478–484)
Mimips Eggers, 1932:33. Type-species: *Ips pilosus* Eggers, original designation (Synonymy and references in Wood & Bright c1992:478)
Isophthorus Schedl, 1938:173. Type-species: *Isophthorus quadrituberculatus* Schedl, subsequent designation by Wood 1980:89 (Synonymy and references in Wood & Bright c1992:478)

Diagnosis: *Acanthotomicus* is distinguished from other Ipini by the large, coarsely faceted eye in which

the lower half is subequal in area with the upper half above the emargination; by the more pronounced sexual dimorphism; and by the very different antennal club, which is often minutely pubescent and devoid of sutures (or sutures, when present, strongly procurved).

Description: Length 1.6–2.9 mm, 2.4–3.0 times as long as wide; color yellowish to reddish brown. Frons dimorphic in American species, convex or partly impressed in male, more broadly flattened to impressed and pubescent in female; eye large, coarsely faceted, shallowly emarginate, lower half equal in area to area above emargination; antennal scape elongate, funicle 5-segmented, club subcircular, moderately large, strongly flattened, sutures (when present) strongly procurved. Pronotum longer than wide, summit near middle, declivous on anterior half. Scutellum rather large, flat. Elytra striate; declivity rather steep, broadly excavated, lateral margins usually elevated and dentate, subapical margin rather strongly elevated; female usually less strongly sculptured than male.

Distribution: Wood & Bright (c1992:478–484) record 96 species from tropical and subtropical areas. Of these, 8 occur in South America and 3 more in adjacent Central America.

Biology: All species are phloeophagous. Of the 13 species observed in nature by me, 1 is monogynous, the others polygynous. Most species breed in cut or broken limbs and branches. At least a third of the neotropical species infest the lower bole of rather large trees.

Key to American Species of *Acanthotomicus*

- 1. Elytral declivity more narrowly (usually), more strongly concave, its upper and lateral margins armed by two to four pair of pointed denticles, at least one pair on lower half of declivity 2
- Elytral declivity shallowly to moderately more broadly (subcircularly) impressed, usually concave, its upper (basal) margin armed by pointed denticles on interstriae 2 and 3, denticles never present on margins of lower half of declivity 6
- 2(1). Declivity armed by two pair of spines on basal margin, spine 1 at interstriae 1, spine 2 at interstriae 2, and one very large, blunt spine on lateral margin at or slightly below middle; body much more slender, 3.0 times as long as wide; Brazil (MT); *Hevea brasiliensis*; 2.0 mm *flechtmanni* Wood
- Basal and lateral margins of declivity armed by three or more pair of denticles of about equal size (middle denticle sometimes slightly larger in male); body less slender, 2.4 times as long as wide 3
- 3(2). Spine on lateral margin of declivital interstriae 3 appearing to have a double base, lower element much larger; Brazil (Para); 2.6 mm *duplicatus* Schedl

- Spine on declivital interstriae 3 appearing to have a double base, upper element much larger, pointed 4
- 4(3). Spine on lateral margin of declivital interstriae 3 usually appearing to have a double base (lower element usually absent), small spine on margin at interstriae 4 almost always absent, spine on interstriae 5 present; Venezuela (Barinas); *Spondias mombin*; 1.9–2.2 mm **analogus** (Wood)
- Spine on lateral margin of declivital interstriae 3 with a hump on lower element, small spines present on 4 and 5 5
- 5(4). Male frons moderately impressed on lower half, gradually transcending to convex upper half, surface shining, punctured, weak granules rarely present; anterior margin of pronotum rather coarsely serrate; elytral setae mostly smaller, less abundant, tips of most blunt; Mexico (Veracruz) and Jamaica to Venezuela and Brazil (Bahia); *Spondias mombin*; 1.6–2.0 mm (to 2.3 mm in Brazil) **mimicus** (Schedl)
- Male frons abruptly, more strongly, transversely impressed on lower half, upper area rather coarsely tuberculate; anterior margin of pronotum unarmed to weakly serrate; elytral setae more abundant, much longer, tips strongly pointed; Costa Rica; blacklight; 2.2–2.3 mm **ipsiformis** Wood
- 6(1). Declivity very shallowly concave, all margins rounded, a very small, pointed tubercle on basal margin at interstriae 2, minute granules, sometimes on lateral margin (variable); disc and parts of declivity with fine, confused, recumbent, hairlike ground setae, rows of erect interstitial setae also present; eyes very large, coarsely faceted, separated above by distance 1.2 times width of an eye; Colombia (Valle de Cauca); *Icica altissima*; 1.8–2.1 mm **ocularis** (Wood)
- Elytral declivity more strongly concave, lateral margin on lower half subacutely elevated; larger species 7
- 7(6). Base of elytral declivity armed by two pair of denticles, one on interstriae 2 and one on interstriae 3; frons punctate-tuberculate in both sexes, lower half transversely impressed, moderately in male, weakly in female; Costa Rica to Panama; tree limbs and bole; 2.4–2.8 mm **fortis** (Wood)
- Base of declivity armed by one pair of pointed denticles; frons variable 8
- 8(7). Base of declivity on interstriae 3 armed by one pair of stout, blunt denticles; male frons with median line impunctate, a rounded median elevation near middle, lateral areas obscurely subreticulate and with rather sparse, moderately abundant granules, female frons finely, densely punctured except median line at least partly impunctate, median elevation absent; Colombia (Valle de Cauca); *Icica altissima*; 2.3–2.4 mm **bidentis** Wood
- Base of declivity on interstriae 2 armed by one pair of small pointed denticles 9
- 9(8). Punctures of elytral striae larger, deeper, interstriae about three times as wide as striae; spine at base of male declivity more slender, longer, apex hooked and directed mesad; declivital punctures larger; Venezuela; tree branch; 2.6–2.9 **granulatus** (Ferrari)
- Punctures of elytral striae and interstriae minute, interstriae six or more times as wide as striae; spine at base of male declivity shorter, directed caudad 10
- 10(9). Male declivity less strongly impressed, spine at base shorter, conical, wider than long, granules on lateral margins obsolete; declivital setae less abundant, finer; Bolivia; 3.0 mm **bolivianus** (Eggers)
- Male declivity more strongly impressed, spine at base longer, about 1.5 times as long as its basal width; declivital setae more numerous, coarser; Panama; 2.3–2.6 mm **chriquensis** (Blandford)

Acanthotomicus flechtmanni Wood, n. sp.

Acanthotomicus flechtmanni Wood: Holotype ♂; Itiquira River, Mato Grosso, Brazil; MZUSP, Sao Paulo, designated below

Diagnosis: Members of this species group resemble small *Ips* species that have three or four pair of denticles arming the upper and lateral margins of the elytral declivity and a subacutely elevated, transverse lower margin; this species is distinguished from others in this group by the small size; by the very slender body; and by the presence of pairs of spines on the declivity.

Male: Length 2.0 mm, 3.0 times as long as wide; color reddish brown. Frons rather weakly convex on upper two-thirds, slightly elevated toward epistoma; surface above reticulate, a few minute granules on marginal areas; epistomal process on median third appearing weakly, acutely elevated; vestiture of fine, sparse, inconspicuous hair; antennal club small, as long as scape, slightly longer than wide, distal half pubescent, sutures not evident (view obscured on specimen at hand). Pronotum 1.5 times as long as wide; sides on about posterior two-thirds straight and parallel, rather broadly rounded in front, anterior margin feebly serrate; declivous and weakly asperate on anterior third; posterior areas smooth, shining, small punctures moderately abundant; vestiture of fine, erect hair of moderate abundance and length. Elytra 1.5 times as long as wide, 1.1 times as long as pronotum; surface of disc shining, obscurely irregular; striae not evident, punctures small, shallow, moderately confused with those of interstriae. Declivity confined to posterior fourth, rather abrupt, very steep, broadly, shallowly concave; lateral margin moderately elevated, armed by a small, pointed denticle on interstriae 1, a slightly larger denticle on 2, a very large, blunt denticle on margin at middle of declivity, margin below denticle 3 distinctly, subacutely elevated; face of declivity smooth, shining, with moderately numerous small punctures. Vestiture on disc of fine, rather short, erect hair; setae longer and more abundant on declivity.

Distribution: Brazil (Mato Grosso).

Type material: The male holotype was taken at Itiquira River, Mato Grosso, MT, 15-VIII 1992, ethanol trap in *Hevea brasiliensis* stand, O. Dall'Oglia. The holotype is in MZUSP, Sao Paulo.

Acanthotomicus duplicatus (Schedl)

Acanthotomicus duplicatus (Schedl), 1973:170 (*Mimips*). Holotype ♂; Rio Papagaio, Utiariti, Brazil, Brazil; 325 m; MZUSP, Sao Paulo (References in Wood & Bright c1992:480)

Diagnosis: Distinguished from *mimicus* (Schedl) by the larger size; by the second denticle (on interstriae 3) with the lower element larger; and by other characters described below.

Male: Length 2.6 mm, 2.8 times as long as wide; color rather dark reddish brown. Frons reticulate, broadly convex, a short, shining median carina above middle of frons length; surface with moderately abundant, rather

coarse tubercles on upper half, becoming smaller to obsolete at epistoma; vestiture not evident; antennal club almost as wide as long, sutures 1 and 2 strongly procurved, marked by setae and weak grooves, 1 extending slightly beyond middle of club length. Pronotum 1.2 times as long as wide; sides straight and parallel on basal half, broadly rounded on unarmed anterior margin; summit slightly anterior to middle, anterior slope closely asperate; posterior half smooth, shining, punctures moderately coarse, close; almost glabrous. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; surface shining, some irregular obscurely impressed lines; punctures distinctly impressed, of moderate size, mostly confused, not in clearly defined rows. Declivity steep, broadly, moderately concave; spine 1 on margin at interstriae 2 rather small, blunt, poorly defined; spine 2 on interstriae 3 large, with a double base, lower element larger, blunt, poorly defined, spine 3 smaller (on interstriae 4), spine 4 distinctly larger, blunt; apical margin on lower third moderately elevated, subacute, crest undulating slightly; face shining, punctures rather coarse, close, confused. Almost glabrous.

Distribution: Brazil: Para, Cachimbo, VI-1962, Oliveira & Alvarenga.

Notes: The above treatment was based on the male paratype at NHMW, Wien.

Acanthotomicus analogus (Wood)

Plate LXVII

Acanthotomicus analogus (Wood), 1971:40 (*Mimips*). Holotype ♂; 40 km E Canton, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:478)

Diagnosis: Distinguished from others in this species group by the uniformly elevated subapical margin of the declivity (not undulating); by the small tubercle on interstriae 4 not basally united with spine on interstriae 3; and by the weak frontal impression.

Male: Length 1.9–2.2 mm, 2.4 times as long as wide; color yellowish brown. Frons convex above, rather strongly, transversely impressed on lower half, surface basically smooth, shining, with moderately abundant, fine tubercles uniformly distributed from epistoma to upper level of eyes; vestiture of long, fine, rather sparse hair; antennal club as long as scape, slightly longer than wide, suture 1 not septate, strongly procurved, attaining middle of club. Pronotum 1.1 times as long as wide; summit at middle, anterior half declivous, moderately asperate; posterior areas shining, almost smooth, punctures rather coarse, separated by less than diameter of a puncture; vestiture of rather sparse, long hair; more conspicuous at margins. Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures rather coarse, moderately deep; interstriae slightly more than twice as wide as striae, smooth, shining, punctures two-thirds as large as those of striae, similarly impressed. Declivity occupying posterior one-third of elytral length, broadly, moderately concave, steep;

face smooth, shining, punctures rather coarse, close, moderately confused; lateral and lower margins subacutely elevated except crest absent near suture above; denticle 1 pointed, conical, on margin at interstriae 2, denticle 2 on 3, larger, pointed, base extended slightly ventrad, denticle 3 slightly below middle, pointed, larger than 2 (a small cusp sometimes present between 2 and 3); apical margin below 3 subacute, moderately elevated, summit undulating in height. Vestiture of erect hairlike setae in stria (short) and interstitial (longer) rows, shorter on declivity.

Female: Similar to male except frons more uniformly convex, closely, finely punctured; punctures on pronotum and elytra slightly smaller; declivity less strongly concave, lateral margins not as high, denticles smaller (2 without basal extension), apical margin lower, of uniform height.

Distribution: Venezuela: 40 km E Canton Barinas, 8-III-1970, 70 m, No. 394, *Spondias mombin*, SLW.

Biology: Boring radiate tunnels in the phloem of cut and broken branches 3–8 cm in diameter. When competing for space with *mimicus analogus* was confined to the larger branches.

Notes: The above treatment was based on the type series of 31 specimens from Venezuela.

Acanthotomicus mimicus (Schedl)

Plate LXIX

Acanthotomicus mimicus (Schedl), 1961:227 (*Mimips*). Holotype ♂; Turrialba, Costa Rica; NHMW, Wien (References in Wood & Bright c1992:482)

Diagnosis: Distinguished from other members of this species group by the small size; by the basal union of spine on declivital interstriae 3 to prominence on 4 incomplete, all spines smaller; and by the crest on the subapical, lower margin undulating.

Male: Length 1.6–2.0 mm, 2.4 times as long as wide; color yellowish brown. Frons similar to *analogus* Wood, impression and tubercles less definite; antennal club suture 1 less strongly arcuate, 2 indicated. Pronotum and elytral disc resembling *analogus* except punctures not as deep. Declivity resembling *analogus* except denticles 1 and 2 slightly larger; lower (ventral) base of 2 forming a separate cusp, a second cusp present before smaller denticle 3, apical margin more acutely raised, crest undulating in height.

Female: Similar to male except frons more finely, more densely punctured, setae much more dense and longer; elytral declivity less strongly concave, denticles and cusps present but smaller; apical margin of more uniform height.

Distribution: Mexico (Veracruz), Hispanola (Dominican Republic), and Jamaica to Venezuela and Brazil.

Brazil: Bahia, Cepec, Ilheus, 11-III-1981, blacklight, Kaston; "Santa Catarina."

Venezuela: 9 km S Barrancas, Barinas, 5-XII-1969, 150 m, No. 115, *Spondias mombin*, SLW; 40 km E Canton, Barinas, 8-III-1970, 70 m, No. 394, *Spondias mombin*, SLW.

Biology: Boring in phloem of recently broken and felled stems 3–10 cm in diameter. When intermixed with *analogus*, *mimicus* usually selected the smaller stems and *analogus* the larger stems.

Notes: The above treatment was based on 56 specimens from Costa Rica and Panama and 93 from Venezuela. Several specimens were examined from Santa Catarina (Brazil) but the data were not recorded.

Acanthotomicus ocularis (Wood)

Plate LXIX

Acanthotomicus ocularis (Wood), 1971:42 (*Mimips*). Holotype ♂; Carton de Colombia forest 8 km S Colonia (near Buenaventura), Valle de Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:482)

Diagnosis: Distinguished from all other American members of this genus by the very shallowly concave elytral declivity, with all margins rounded, the basal margin armed on interstriae 2 by one pair of small denticles; and by the unusually large, coarsely faceted eyes that are narrowly separated above.

Male: Length 1.8–2.1 mm, 2.7 times as long as wide; color reddish brown. Frons convex, a weak, transverse impression on median half of lower half, shining, convex area with rather small, moderately numerous tubercles; impressed area usually with at least a few longitudinally impressed fine lines; vestiture rather short, sparse; eyes rather narrowly separated above by 1.1 times width of an eye; antennal club as wide as long, pubescent to base, suture 1 rather obscure, not septate. Pronotum 1.1 times as long as wide; summit in front of middle, asperate on anterior half, anterior margin armed by low serrations; posterior areas shining, almost smooth, punctures small, rather close; vestiture rather sparse, hair-like. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures not in rows; interstriae smooth, shining, punctures of equal size, most confused with those of striae. Declivity rather steep, margins rounded, face shallowly concave; a very small, pointed denticle at upper margin on interstriae 2; crest of lateral margin with about 4 fine granules scattered along summit; subapical lower margin rounded. Vestiture of moderately abundant fine, short, recumbent hair on disc and declivity; declivity also bearing short, erect, stout bristles in rows on interstriae 1–3 and on lateral areas.

Female: Similar to male, except frontal setae more abundant and much longer; erect declivital bristles apparently, slightly longer and more slender.

Distribution: Colombia: Carton de Colombia forest 8 km S Colonia (near Buenaventura), Valle de Cauca, 9-VII-1970, 70 m, No. 628, *Icica altisma*, SLW.

Biology: Boring radiate tunnels in the phloem of a small, dying tree seedling about 5 cm in diameter.

Notes: The above treatment was based on the type series of 19 specimens from Colombia.

Acanthotomicus bidentis Wood

Plate LXVIII

Mimips bidens Wood, 1971:41. Holotype ♂; 8 km S Colonia (near Buenaventura), Valle de Cauca, Colombia; USNM, Washington, preoccupied by Schedl 1967:229

Acanthotomicus bidentis Wood, 1972:191. Holotype ♂; Carton de Colombia forest 8 km S Colonia (near Buenaventura), Valle de Cauca, Colombia; USNM, Washington, automatic (Synonymy and references in Wood & Bright c1992:479)

Diagnosis: Base of declivity armed by one pair of stout denticles on interstriae 3; female frons rather densely, finely punctured, male with median line impunctate and a small median elevation near middle.

Male: Length 2.3–2.4 mm, 2.6 times as long as wide; color reddish brown. Frons moderately convex, surface obscurely subreticulate, with moderately abundant, isolated tubercles from epistoma to above eyes; median line at middle with a moderate elevation, a weak, obscure continuation extending to vertex; vestiture sparse, inconspicuous, more abundant on epistomal margin; eyes widely separated; antennal club slightly longer than wide, basal segment smooth, shining, suture 1 strongly procurved, indicated by pubescence. Pronotum about as in *ocularis* except posterior areas mostly reticulate. Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures in rows, small, not strongly impressed; interstriae about three times as wide as striae, surface smooth, shining, punctures in rows, slightly smaller than those of striae. Declivity abrupt, steep, broadly, rather deeply concave; margin rounded at base of interstriae 1–2, 3 armed at base by a coarse, blunt spine, subapical margin acutely, rather strongly elevated from spine to suture near apex, crest of margin wavy near spine; face smooth, shining, confused punctures close, rather coarse, moderately deep. Vestiture hairlike, rather short, largely restricted to sides and declivity.

Female: Similar to male except frons more broadly convex, tubercles smaller, more numerous, vestiture longer, much more abundant; declivital spine nearer to suture, short, blunt; subapical margin less strongly elevated, crest rounded near spine.

Distribution: Colombia: 8 km S Colonia (near Buenaventura), Valle de Cauca, 9-VII-1970, 30 m, No. 628, *Icica altissima*, SLW.

Biology: Boring radiate tunnels in the phloem of a dying tree seedling about 5 cm in diameter.

Notes: The above treatment was based on the type series of 97 specimens from Colombia.

Acanthotomicus granulatus (Ferrari)

Plate LXVIII

Acanthotomicus granulatus (Ferrari), 1867:40 (*Xylocleptes*). Lectotype ♂; Venezuela, Moritz (presumably Colonia Tovar, Aragua, near the Moritz home); NHMW, Wien, designated by Wood 1974:277 (Synonymy and references in Wood & Bright c1992:481)

Mimips uncinatus Wood, 1971:41. Holotype ♂; Colonia Tovar, Aragua, Venezuela; USNM, Washington

Diagnosis: Distinguished from *chiriquensis* (Blandford) by the declivital spines on interstriae 2 directed primarily mesad; and by the larger punctures on the elytral disc and declivity.

Male: Length 2.6–2.9 mm, 2.6 times as long as wide; yellowish brown to reddish brown. Frons about as in *bidentis* (Wood); antennal club with 2 strongly procurved sutures indicated by setae. Pronotum about as in *bidentis*, disc obscurely reticulate. Elytra much as in *fortis* (Wood) except spines at base of declivity much closer to one another (on interstriae 2), these spines pointed mesad (not caudad as in *chiriquensis*).

Female: Similar to male, except frons more broadly convex, more finely, more closely punctured, obscure granules reduced to obsolete, frontal vestiture longer, more abundant; declivital spines slightly smaller, lateral and apical margins less strongly elevated.

Distribution: Colombia?; “Colombie,” Moritz (presumably taken near the Moritz home at Colonia Tovar, Venezuela).

Venezuela: Colonia Tovar, Aragua, 4-V-1970, 1700 m, No. 498, tree seedling, SLW.

Biology: Boring in the phloem of a dying tree seedling.

Notes: The above treatment was based on 62 specimens from the type locality [this was the type series of *uncinatus* Wood (= *granulatus*)] that was taken less than 500 m from the Moritz home). The holotype of *uncinatus* was compared by me directly to the lectotype of *granulatus* (Ferrari).

Acanthotomicus bolivianus (Eggers)

Acanthotomicus bolivianus (Eggers), 1943:357 (*Isophthorus*). Holotype ♂; Cochabamba; NHMW, Wien (References in Wood & Bright c1992:479)

Diagnosis: Distinguished from *chiriquensis* (Blandford), from Panama, by the larger size; by the less strongly impressed elytral declivity; by the smaller, conical spine 1 at the base of the declivity; by the absence of granules on the lateral crest of the declivity; and by the subaciculate frons.

Male: Length 3.0 mm, 2.8 times as long as wide; color dark reddish brown. Frons shining, rather finely, convergently aciculate from epistoma to above upper level of eyes, punctures obscure; vestiture of rather abundant long hair uniformly distributed. Both antennae missing from type. Pronotum 1.06 times as long as wide; sides feebly arcuate on basal half, anterior margin broadly rounded, armed by about 12 small serrations; summit slightly anterior to middle, anterior slope closely asperate; posterior areas mostly shining, with areas of weak reticulation especially near punctures, punctures rather small, moderately close. Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; striae 1 weakly impressed, others not impressed, punctures very small, distinct; interstriae smooth, brightly shining, about five times as wide as striae, punctures slightly smaller than those of striae, distinct, uniseriate. Declivity steep,

broadly, shallowly concave, surface shining, suture distinctly elevated, not as high as lateral margins; lateral margin subacutely elevated near sutural apex, obtusely, rather narrowly rounded to spine 1 on interstriae 2 at base, margin not elevated from suture to spine 1; spine 1 conical, pointed, its length about equal to its basal width; punctures on face of declivity rather small, confused, moderately numerous. Vestiture of very small, fine strial hair and rows of longer, erect interstitial hair (mostly abraded on disc and declivity of type).

Distribution: Bolivia: Cochabamba [F. Woytkowski].

Notes: The above treatment was based on the male holotype from Bolivia, presumably a male.

GENUS *ORTHOTOMICUS* FERRARI

Orthotomicus Ferrari, 1867:44. Type-species: *Bostrichus laricis* Fabricius, subsequent designation by Hopkins 1914:126; original spelling of *Orthotomicus*, lapsus calami, corrected by Ferrari 1869:256 to *Orthotomicus* (Synonymy and references in Wood & Bright c1992:467)

Neotomicus Fuchs, 1911:33. Type-species: *Bostrichus laricis* Fabricius, subsequent designation by Hopkins 1914:126

Pseudips Cognato, 2000:365. Type-species: *Bostrichus concinnus* Mannerheim, original designation. *New synonymy*

Diagnosis: Antennal club varying from obliquely truncate to sutures weakly to strongly recurved or weakly to strongly procurved. It is distinguished from *Ips* by the steeper elytral declivity, with the lateral margins armed by three or fewer pair of spines (a few males may have 4 pair), the ventrolateral subapical margin is commonly wavy or undulating in height (or both), and the lateral margin less strongly elevated; and by the more pronounced sexual dimorphism.

Description: Length 2.0–3.7 mm, about 2.5 times as long as wide; color dark reddish brown. Frons convex, variously granulate-punctate in both sexes, vestiture sparse, often inconspicuous; eye elongate-oval, shallowly emarginate, narrower on lower half; antennal scape elongate, funicle 5 segmented, club varying from obliquely truncate to sutures on anterior face either procurved or recurved, sutures on posterior face displaced to apex. Pronotum longer than wide, summit at middle, anterior slope declivous and asperate, posterior area punctate. Elytra striate; declivity abrupt, broadly excavated (less than in *Ips*), lateral margins armed by 3

pair of spines or fewer (four in a few males), more weakly elevated than in *Ips*, lowest denticle often displaced mesad; sexual dimorphism moderate.

Distribution: Wood & Bright (c1992:467–478) list 1 species from North America and 7 from Asia (only), plus 5 additional species from Asia that also extend into Europe (and 1 of these also into northern Africa). With the present realignment of species in *Orthotomicus*, the North American *concinnus* group of species [(*concinnus*, *mexicanus* Hopkins) plus *orientalis* Wood & Yin (China)] were transferred from *Ips* to *Orthotomicus* by Lanier (1966). Also transferred from *Ips* to *Orthotomicus* is the *erosus* group of species [*latidens* LeConte and *spinifer* Eichhoff (from North America) and *erosus* Wollaston and *robustus* Knotek (from Europe and Asia)].

Biology: The habits are essentially as described above for the tribe. The galleries are of the radial type in polygynous species or longitudinally biramous in monogynous species. At least several species (all?) may deposit more than 1 egg in an egg niche.

Taxonomy: The alignment of species outlined above removes from *Ips* 2 species groups that are structurally, biologically, and behaviorally intermediate between a now more compact *Ips* and a more diverse *Orthotomicus*, which has been based on the allies of *laricis* to which the *erosus* and *concinnus* groups of species are now added. The elytral declivities of both species groups are more nearly similar to other *Orthotomicus*, but the antennal club of the *erosus* group more nearly resembles *Ips*, while in the *concinnus* group the sutures are very strongly procurved as in some *Acanthotomicus*. Two apparent unifying characters in this alignment of *Orthotomicus* are (1) the habit of placing more than 1 egg in an egg niche (universal?), and (2) a reduced number of chromosomes (N = 7).

More than 2 years after the above paragraph was written, Cognato (2000:365) named *Pseudips* as a genus containing *concinnus* (Mannerheim), *mexicanus* (Hopkins), and *orientalis* Wood & Yin, without studying the Asiatic *Orthotomicus*. When the full diversity of the Asian and European *Orthotomicus* is examined, Cognato's genus cannot stand as a distinct genus, or even as a distinct species group.

Key to the Species of *Orthotomicus*

- 1. Antennal club thicker at base (segment 1), suture 1 almost straight, 2 distinctly recurved; declivity less deeply excavated, margin armed by three pair of denticles, denticle 3 displaced slightly mesad from lateral margin; Europe, Asia, introduced elsewhere, including South America (Chile); *Pinus*, *Picea*; 3.0–3.7 mm ***laricis* (Fabricius)**
- Antennal club more strongly flattened, sutures 1 and 2 distinctly procurved; declivity more deeply excavated, lateral margins armed by four pair of denticles, last pair on lateral margin (not displaced mesad); Europe, Asia, introduced elsewhere, including South America (Chile); *Pinus*; 2.6–3.3 mm ***erosus* (Wollaston)**

Orthotomicus laricis (Fabricius)

Orthotomicus laricis (Fabricius), 1792:365 (*Bostrichus*). Syntypes 8, sex?; Germaniae; UZMC, Copenhagen (References in Wood & Bright c1992:469)

Diagnosis: Distinguished from *erosus* (Wollaston) by the thicker base of the antennal club (essentially, obliquely truncate), with sutures feebly to distinctly recurved; by the elytral declivity being armed by three pair of pointed denticles, with denticle 3 displaced mesad from the lateral margin; and by the steeper, less deeply excavated elytral declivity.

Male: Length 3.0–3.7 mm, 2.7 times as long as wide; color very dark reddish brown. Frons broadly convex, a weak transverse impression on lower third; surface reticulate, rather finely, not closely punctured; hairlike setae sparse, long, fine; antennal club basally thickened, almost obliquely truncate, sutures distinctly recurved. Pronotum 1.17 times as long as wide; moderately declivous and coarsely asperate on anterior two-fifths, posterior half smooth, shining, moderately, rather coarsely punctured; sparse vestiture of long hair, mostly on sides and in front. Elytra 1.55 times as long as wide, 1.4 times as long as pronotum; striae 1 slightly impressed, others feebly impressed, punctures rather small, close, uniseriate. Declivity occupying about one-sixth of elytral length, very steep, shallowly, broadly concave; lateral margin obtusely elevated on upper two-thirds, rather acutely on lower third, armed by three pair of pointed spines, spine 1 on interstriae 1, 2 on interstriae 2, and 3 distinctly below middle of declivity and slightly displaced mesad from lateral margin; face broadly, moderately concave, with close, rather coarse, confused punctures. Vestiture of erect interstitial hair of moderate length, mostly on sides and declivity.

Female: Similar to male except frontal impression weaker, elytral declivity not as strongly impressed, lateral margins usually less strongly elevated, spines slightly smaller.

Distribution: Northern Africa, Europe, northern Asia, introduced into South America (Chile).

Chile: "Chile" (Wood & Bright c1992:469).

Hosts: *Pinus* (also *Picea*, *Larix* in Europe and Asia).

Biology: Phloeophagous in large stems (not seen by me).

Notes: The above treatment was based on more than 100 specimens from Europe and 9 from Asia. South American specimens were not seen by me.

Orthotomicus erosus (Wollaston)

Plate LXVII

Orthotomicus erosus (Wollaston), 1857:95 (*Tomicus*). Syntypes, sex?; Madera; BMNH, London (References in Wood & Bright c1992: 504–506)

Tomicus rectangulus Ferrari, 1867:83. Five syntypes, sex?; Gall. merid. et Algeria; not located

Diagnosis: Distinguished from *laricis* (Fabricius) by the larger, very strongly flattened antennal club, with

sutures 1 and 2 distinctly procurved; by the elytral declivity being armed by four pair of denticles, all on the lateral margin; and by the less steep, more strongly excavated elytral declivity.

Male: Length 2.6–3.3 mm, 2.7 times as long as wide; color dark reddish brown. Frons broadly convex, a weak, transverse impression on lower third; surface shining, rather coarsely granulate-punctate; vestiture of sparse, long hair; antennal club slightly wider than long, strongly flattened, sutures 1 and 2 moderately procurved. Pronotum 1.12 times as long as wide, about as in *laricis*. Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; striae 1 distinctly, others feebly impressed, punctures rather small, deep, close; interstriae about twice as wide as striae near base, about 1.5 times near declivity, punctures small, sparse on basal half, larger near declivity. Declivity occupying one-fourth of elytral length, steep, broadly, strongly concave; interstriae 2 armed at base by a moderately coarse, pointed, conical spine; middle third of lateral margin acutely elevated and armed by pointed spines of moderate size on interstriae 3 (displaced laterad, appearing as if on 4), 5 and 7; ventral margin moderately, acutely to subacutely elevated from suture to base of spine 4, crest of its lateral half undulating and/or wavy; face shining, punctures coarse, close, confused. Vestiture of erect interstitial hair, mostly on sides and declivity.

Female: Similar to male except less coarsely sculptured, tubercles and spines slightly smaller.

Distribution: Northern Africa, Europe, northern Asia, introduced to South Africa, Fiji, and South America (Chile).

Chile: "Chile" (Wood & Bright c1992:504).

Hosts: *Pinus* (rare in *Abies*, *Cedrus*, *Picea* in Europe and Asia).

Biology: This species was introduced into Chile, where it came into unsuccessful ecological competition for the same niche occupied by *Hylurgus ligniperda* (Fabricius). It is now rarely found there (USDA 1990, Pest Risk Assessment for importation of solid wood packing material into the United States, p. 221). It bores in phloem tissues of the host.

Notes: The above treatment was based on 16 specimens from Europe and on 2 from the Canary Islands (Teneriffe), which had been identified by A. Pfeffer and F.G. Browne. South American specimens were not seen by me but have been reported in the literature.

GENUS *IPS* DEGEER

Ips DeGeer, 1775:190. Type-species: *Dermestes typographus* Linnaeus, subsequent designation by Bergroth 1884:230 (Synonymy and references in Wood & Bright c1992:485)

Cumatotomicus Ferrari, 1867:44. Type-species: *Bostrichus stenographus* Duftschmidt = *Dermestes sexdentatus* Boerner subsequent designation by Hopkins 1914:119

Cyrtotomicus Ferrari, 1867:44. Type-species: *Bostrichus acuminatus* Gyllenhal, subsequent designation by Hopkins 1914:120

Diagnosis: Distinguished from *Orthotomicus*, as revised above, by the more gradual, more deeply excavated elytral declivity, with the lateral margins armed at their summit by three to six pair of denticles, and with the ventrolateral, subapical margin more strongly (acutely) elevated, its crest of constant height; and by the (usually) less conspicuous sexual dimorphism.

Description: Length 2.1–6.7 mm, 2.4–2.8 times as long as wide; color yellowish brown to almost black, vestiture hairlike. Frons simple to strongly, sexually dimorphic; eye finely faceted, shallowly emarginate, lower half distinctly narrower than upper half; antennal club sub-circular to oval, strongly flattened, sutures 1 and 2 on anterior face weakly bisinuate to strongly angulate. Pronotum and elytral disc about as in *Orthotomicus*; declivity concavely excavated, summit of lateral margins armed by three to six pair of denticles (none of them displaced mesad), apical margin more strongly, more uniformly elevated (not undulating or wavy).

Distribution: Wood & Bright (c1992:484–538) report 43 species in the world fauna, none from South America. A majority of the species breed in *Pinus* species and are a potential threat to *Pinus* plantations everywhere; other species infest *Picea*, *Larix*, and (rarely) other hosts. Two species, *calligraphus* (Germar) and *grandicollis* (Eichhoff),

have been introduced into Australia and the Antilles Islands (Bahama, Cuba, Hispanola). One oral report from South America of an *Ips* species introduction may have been based on an error in identification, presumably of an *Orthotomicus* species.

Biology: The habits are basically as described for the tribe. All species are polygynous and phloeophagous. The parent galleries are of the radial type. The eggs are deposited individually in separate niches. Most species breed in windfalls, felled or broken trees or slash and, usually, are of minor economic concern. However, some species are moderately to strongly aggressive and are capable of becoming epidemic (especially with introductions into new geographical areas).

Taxonomy: See the alignment (above) under *Orthotomicus* for those former *Ips* species that are presently transferred to *Orthotomicus*.

Notes: South American species of *Ips* have not been reported. However, in view of the large plantations of *Pinus* spp. that exist in South America and because several species of *Ips* are known to have been transported to extra-territorial areas, it is only a matter of time before they will become a significant problem in South America.

TRIBE DRYOCOETINI

Description: Frons usually sexually dimorphic, male convex to variously impressed, female convex to flattened or with elevations, ornamented by setae in some species; eye emarginate to divided (exotic species only); antennal scape elongate, funicle 4- to 6-segmented, club obliquely truncate to strongly flattened, when flattened sutures variously procurved to obsolete, on posterior face sutures strongly displaced toward apex; pronotum anteriorly declivous or not, armed by asperities or not; pro-coxae contiguous to narrowly separated; protibia with lateral margin armed by 3 or more socketed denticles; scutellum visible; elytral declivity usually convex, rarely shallowly sulcate or flattened, sometimes bearing small granules; vestiture hairlike.

Biology: Apparently all are polygynous, most are normally bisexual (with diploid males that join females in formation of new parental galleries). *Dryocoetiops*,

Coccotrypes, and *Ozopemon* apparently have haploid males that are variously dwarfed and cannot fly from the brood host. *Dactylotrypes* and some *Coccotrypes* are spermophagous; 1 New Guinea species, *Dryocoetiops* [*coffae* (Eggers)] is myelophagous. In phloeophagous genera, eggs are placed individually in niches (except *Ozopemon*); in *Dryocoetiops*, most *Coccotrypes*, and *Ozopemon*, they are deposited in clusters in the brood chamber.

Taxonomy: This is a large and inadequately studied diverse group. Only 4 of the known 17 genera in the world fauna occur in South America. Two of these (*Dryocoetes*, *Coccotrypes*) were introduced from the eastern hemisphere; 2 are endemic (*Dendrocranulus*, *Chiloxylon*). The habits of *Chiloxylon* are entirely unknown.

Key to the Genera of Dryocoetini

- 1. Lateral margin of protibia armed by 5 or more socketed denticles; male diploid, capable of flight, subequal in size to female, joins female in parental gallery formation 2
- Lateral margin of protibia armed by 2–4 socketed denticles; 3
- 2(1). Antennal club strongly flattened pubescent, basal area not corneous, sutures obscure, procurved; Cucurbitaceae hosts; 1.2–2.7 mm *Dendrocranulus*
- Antennal club obliquely truncate, basal area corneous and glabrous, sutures obscure, recurved; Pinaceae hosts; 1.5–5.1 mm *Dryocoetes*
- 3(1). Protibia rather broad apically, lateral apical angle abrupt (almost 90 degrees), 1 denticle on this angle, another on apical margin, and a third on lateral margin one fourth tibia length from apical angle; funicle 4-segmented, club constricted at partly septate suture (not actually, obliquely truncate), suture 2 indicated by setae; habitus resembling *Dryocoetes*, uniseriate interstitial setae almost scalelike on declivity, declivity very steep; strial punctures coarse, deep; (biology unknown 1.7 mm *Chiloxylon*
- Protibia narrowed near apex, outer apical angle not abrupt; funicle 5-segmented, club obliquely truncate or nearly so, sutures never septate; in phloem of various angiosperm/dicot hosts and palm fruits; (male haploid, flightless, dwarfed, occurs only in brood host) 1.3–3.7 mm *Coccotrypes*

GENUS *DENDROCRANULUS* SCHEDL

Dendrocranulus Schedl, 1937:165. Type-species: *Dendrocranulus tardus* Schedl, subsequent designation by Schedl 1938:169 (References in Wood & Bright c1992:550–554)

Diagnosis: This genus is allied to *Xylocleptes* of Europe and Africa. It is distinguished from that genus by the presence of a metatibial groove into which the tarsus can be placed; by the obscure, strongly procurved sutures of the antennal club; and by the neotropical distribution.

Description: Length 1.2–2.7 mm, 2.5–3.0 times as long as wide; color pale yellowish brown to very dark brown. Frons usually sexually dimorphic, male feebly impressed to strongly excavated, female convex to flattened, often with abundant vestiture. Eye finely faceted, oval, emarginate. Antennal scape slender, elongate, funicle 5-segmented, club rather small, circular in outline, strongly flattened, with 2 obscure, strongly procurved sutures marked by setae. Pronotum longer than wide, anterior half declivous and asperate; basal and lateral margins rounded. Scutellum small. Elytra elongate, striate; declivity convex to broadly concave, devoid of denticles.

Distribution: Wood & Bright (c1992:550–554) list 44 species from North, Central, and South America, 15 of

which are recorded from South America. Because of the lack of knowledge and the apparent overlap of species between Central and South America, all known species are included in the following key.

Biology: These species breed in the stems of over-mature, injured, cut or broken stems of vines of Cucurbitaceae. Apparently because of the non-economic status of their hosts, none of the species has been studied in detail. The entrance tunnel is made at leaf nodes where an irregular chamber is excavated. At least some of the species are polygynous, others may be monogynous (not yet confirmed). Egg galleries may be rather long. The positioning of eggs has not been reported. Larval mines may be rather long and entirely riddle the central part of the stem. The life cycle is very short. The wet season or winter apparently is passed in litter on the ground (apparently not in the host stems). In 9 months (mid-March to early December) of intense search in Costa Rica during the wet season, not one specimen of this genus was found. When the rains ceased, they were in flight in large numbers and were infesting Cucurbitaceae vines everywhere. They seemed to produce 1 generation then disappeared.

Key to the Species of *Dendrocranulus*
(Modified from Wood 1982:709–711)

- 1. Posterolateral margin of elytra acutely (rather weakly) elevated from sutural apex to interstriae 7 . . . 2
- Posterolateral margin of elytra rounded, declivital face convex to shallowly, broadly concave . . . 8

SCOLYTIDAE OF SOUTH AMERICA

2(1).	Punctures on pronotum disc clearly impressed, tubercles or granules absent	3
—	Punctures on pronotum disc almost entirely replaced by tubercles or granules	6
3(2).	Pronotum rather coarsely punctured over entire surface, entirely devoid of crenulations; ventrolateral margin of declivity subacutely elevated from suture to interstriae 8, tubercles at apex of 7 not joining 8; male frons strongly impressed, female frons ornamented by long setae; Brazil (Santa Catarina); <i>Sapota gonocarpa</i> ; 1.9–2.1 mm	<i>brasiliensis</i> (Schedl)
—	Pronotum closely, rather finely asperate on anterior half; ventrolateral crest of declivity joining interstriae 7 or 8 or obsolete at base of declivity	4
4(3).	Elytral declivity rather strongly convex, striae 2 and 3 straight to their apices; Costa Rica: 1.7–2.0 mm	<i>limus</i> Wood
—	Elytral declivity somewhat flattened, striae 2 and 3 curve toward suture near apex	5
5(4).	Pronotal and elytral punctures smaller, not as deep; elevated posterolateral margin of declivity short sharply defined only near apex; Costa Rica; <i>Sechium edule</i> ; 1.4–1.5 mm	<i>tardulus</i> Wood
—	Pronotal and elytral punctures coarse, deep; posterolateral margin of declivity longer and acutely elevated; Honduras to Costa Rica; <i>Cayaponia macrodonta</i> ; 1.9–2.0 mm	<i>tardus</i> Schedl
6(2).	Disc of pronotum entirely covered by granules or tubercles, few punctures evident; body larger, stouter, 2.4 times as long as wide; Colombia to Venezuela; Cucurbitaceae vine; 1.5–1.7 mm	<i>columbianus</i> Schedl
—	Disc of pronotum shining, punctures indicated, accompanied by impressed lines, some of which lead to or form granules; body much smaller, more slender (2.7 times as long as wide)	7
7(6).	Frons and pronotum shining; declivity more broadly flattened; interstitial setae on declivity stouter, shorter (length slightly less than distance between rows); Mexico (Nayarit) to Honduras; <i>Cayaponia microdonta</i> , <i>Sicydum tamnifolia</i> ; 1.2–1.5 mm	<i>consimilis</i> Wood
—	Frons and pronotum rather strongly reticulate, subshining; declivity more narrowly flattened; interstitial setae on declivity more slender, length slightly greater than distance between rows; Venezuela (Barinas); vine; 1.3–1.4 mm	<i>conditus</i> Wood
8(1).	Declivity slope usually steeper, more narrowly convex, lateral margins more gradually rounded in both sexes, if impressed, interstriae 1 elevated and impression not extending laterad from interstriae 3 in either sex; female frons usually much more strongly pubescent, male frons devoid of excavation or prominent tubercle on vertex	9
—	Declivital slope often more gradual, more broadly convex to shallowly concave, at least in male, impression often extending from suture to striae 4, if convex, male frons strongly impressed and armed by a median elevation on vertex; female frons sparsely to densely pubescent; male mandible usually with inner cusp directed cephalad	27
9(8).	Pronotum disc clearly, rather deeply punctured over at least median half	10
—	Pronotum disc with transverse or flat, rounded granules, occasionally with a few punctures near median line	24a
10(9).	Smaller, more slender species, at least 2.7 times as long as wide	11
—	Larger, stouter species, less than 2.5 times as long as wide	18
11(10).	Disc of pronotum with punctures distinct, without any rugosities; impressions on male frons weak	12
—	Disc of pronotum with punctures accompanied by fine rugosities; impression on lower male frons slightly deeper; punctures on discal interstriae minute, regularly placed	13

DRYOCOETINI

- 12(11). Female frons weakly convex, punctures rather sparse; body more slender; color darker; Costa Rica; vine; 1.3–1.4 mm *pumilus* Wood
- Female frons more nearly flattened, punctures minute, dense, vestiture more abundant; Mexico (Morelos); *Sechium edulis*; 1.3–1.5 mm *gracilis* Wood
- 13(11). Summit on male frons at upper level of eyes rounded, not as high; interstitial setae on declivity slightly longer, more slender (as long or longer than distance between rows) 14
- Summit on male frons at upper level of eyes subacutely elevated; interstitial setae on declivity stouter, most shorter than distance between rows 17
- 14(13). Pronotum disc reticulate; male declivital interstriae 2 more broadly, more strongly impressed, its interstitial punctures obsolete; Mexico (Veracruz); *Luffa acutangula*; 1.9–2.3 mm *sobrinus* Wood
- Pronotum disc smooth, shining or reticulate on disc, punctures on disc near median line less clearly present; male declivity shallowly, more narrowly impressed, with a row of fine interstitial punctures 15
- 15(14). Pronotum strongly reticulate; frons almost uniformly convex, transverse impression on lower half feeble to absent, with reticulation in lateral areas; punctures on discal interstriae 2 and 3 rather sparse; color reddish brown; Costa Rica; vine; 1.2–1.3 mm *vicinalis* Wood
- Pronotum smooth, shining between punctures; frons moderately impressed on lower half, without any reticulation in lateral areas; punctures on discal interstriae 2 and 3 regularly placed 16
- 16(15). Elytral declivity more strongly, evenly convex, interstriae 2 about equal in height to 1 and 3; male frons with median half of lower half almost flat; color reddish brown; Venezuela (Merida); *Cucurbita*; 1.7–2.3 mm *modus* Wood
- Elytral declivity distinctly impressed, particularly interstriae 2 in male; male frons with median half of lower half conspicuously convex; color dark brown to almost black; Brazil (Bahia to Sao Paulo); 1.4–1.8 mm *costalimai* Schedl
- 17(13). Punctures on discal interstriae widely spaced, some by distances two to three times greater than width of an interstriae; transverse impression on male frons less abrupt; male declivital interstriae 2 not impressed, declivity more evenly convex; Mexico (Veracruz) to Honduras; *Cayponia microdonta*; 1.2–1.3 mm *vinealis* Wood
- Punctures on discal interstriae small, regularly placed, spacing never greater than width of an interstriae; transverse impression on male frons more abrupt; male declivital interstriae 2 distinctly impressed; Venezuela (Barinas); vine; 1.3–1.5 mm *reditus* Wood
- 18(10). Disc of pronotum obscurely reticulate in some areas; declivital setae on interstriae 1 and 2 distinctly shorter than distance between rows; male frons reticulate, punctured; female frons moderately convex, reticulate, rather coarsely punctured, with rather sparse, long hair shorter than distance equal to width of antennal club 19
- Disc of pronotum shining, not at all reticulate; male frons shining, with subaciculate sparse rows of fine granules; female frons very finely punctured, with moderately to very abundant, fine, long hair 20
- 19(18). Male frons more narrowly, less strongly impressed on median half, a median callus above upper level of eyes; female frons more coarsely, more distinctly, rugosely punctured, setae mostly longer (almost equal in length to width of antennal club); male declivity convex, impression weaker, extending from suture to striae 2, setae on interstriae 2 stouter, much more closely spaced within row; Costa Rica; vine; 1.7–2.1 mm *securus* Wood

- Male frons broadly, more strongly impressed on median three-fourths, a median callus not evident; female frons more finely, subrugosely punctured, setae much shorter (length equal to less than half width of antennal club); male declivity less strongly convex, much more strongly impressed, impression extending from suture to striae 3, setae on interstriae 2 slender, rather widely spaced within row; Venezuela (Barinas); vine; 2.2–2.4 mm *pinguis* Wood
- 20(19). Smaller species; setae on female frons shorter (length equal to width of antennal club); female frons weakly, more evenly convex, not impressed on lower third; Mexico (Chiapas) to Honduras; *Cayaponia microdonta*; 1.8–2.0 mm *maurus* (Blandford)
- Larger species; setae on female frons much longer (length conspicuously greater than width of antennal club); female frons distinctly, transversely impressed on lower third 21
- 21(20). Pronotum weakly, distinctly reticulate; base of elytral disc near suture almost smooth; declivity steeper; mature color reddish brown; Guatemala to Costa Rica; 2.1–2.8 mm (see also couplet 33) *limbatus* (Blandford)
- Pronotum smooth, shining between punctures and tubercles 22
- 22(21). Setae on declivital interstriae 1–3 longer; more slender, tips sharply pointed, these setae distinctly longer than distance between rows; female frons more strongly convex, vestiture sparse, inconspicuous, margins of oral area with a conspicuous, dense tuft of yellow hair; male frons less strongly, more abruptly impressed; male declivity with punctures on striae 1 and 2 conspicuously larger; deeper; Argentina; 2.4–2.6 mm *barbatus* Schedl
- Setae on declivital interstriae 1–3 uniformly shorter, stouter, blunt, distinctly shorter, each about equal in length to two-thirds distance between rows; female frons with a conspicuous tuft of long hair 23
- 23(22). Pronotal asperities on basal half not as high; interstitial punctures on disc small, half as large as those of adjacent striae; declivital impression slightly deeper; male frons more strongly impressed below, median summit above eyes tuberculate; female frons finely punctured and ornamented by a dense tuft of long, yellow setae, longest setae on upper and lateral margins; Mexico (Oaxaca) to Honduras; 1.7–1.8 mm *maurus* Blandford
- Pronotal asperities on basal half rather coarse; interstitial punctures on disc coarse, almost as large as those of adjacent striae; declivital impression not as deep; male frons below less strongly impressed; female frons with median summit above eyes rounded, uniformly, closely granulate-punctate from epistoma to vertex, setae fine, long, uniformly distributed, not as dense; Mexico (Veracruz); *Sechium edulis*; 2.3–2.6 mm *mexicanus* Wood
- 24a(9). Larger; declivital impression slightly deeper, wider, including all of interstriae 2 (not striae 3); frontal vestiture shorter, less abundant; body 3.0 times as long as wide; Bolivia (Cochabamba); 2.7 mm *major* Schedl
- Smaller than 2.5 mm; declivital impression deepest at striae 1, ascending laterad; frontal vestiture more abundant, mostly near epistoma 24b
- 24b(24a). Larger; interstitial setae on disc and lateral areas of declivity very fine, slender; vestiture on female frons long, rather sparse above; male frons shallowly impressed, a low median elevation above upper level of eyes 25a
- Smaller; interstitial setae on disc and declivity moderately to very coarse, slightly flattened, male frons evenly convex 26
- 25a(24b). Male frons weakly impressed below, a distinct median elevation above upper level of eyes; female frons more weakly convex; more densely punctured, with feeble aciculation on lateral areas, pubescence long, very fine, moderately abundant, uniformly distributed from epistoma to above

DRYOCOETINI

- upper level of eyes; declivity more strongly convex, rather weakly impressed in male, feebly impressed in female; Panama; vine; 1.8–2.3 mm *fulgidus* Wood
- Male frons feebly impressed below, a weak median callus above upper level of eyes; lower one-third of female frons rather densely pubescent, sparsely pubescent above, more strongly convex, less densely punctured; declivity more strongly, more broadly impressed in both sexes 25b
- 25b(25a). Male frons less strongly impressed on lower half, a weak median callus at upper level of eyes; female frons more strongly convex and without a median callus, epistoma with a conspicuous rather dense tuft of long, yellow setae; male declivity more strongly, broadly impressed, declivital setae twice as long, very slightly more slender; Venezuela (Aragua); vine; 1.9–2.3 mm
. *limitaris* Wood
- Male frons more distinctly, broadly impressed on lower half, a weak, distinct median callus above upper level of eyes (female not seen); male declivity less strongly, more narrowly impressed; Brazil; 1.8–2.0 mm *melaenus* (Eichhoff)
- 26(24b). Female frons convex, with a few minute granules, sparsely pubescent; elytral declivity less strongly, more narrowly impressed; Costa Rica; vine; 1.5–1.7 mm *schedli* Wood
- Female frons somewhat flattened, finely punctured, with abundant, long fine pubescence; elytral declivity more strongly, broadly impressed; Honduras to Costa Rica; *Cayaponia microdonta*, *Potakowskia tacaco*; 1.4–1.7 mm *vicinus* Wood
- 27(8). Male declivity feebly, broadly impressed to broadly convex; frons strongly impressed and with a prominent median elevation on vertex; female declivity usually more strongly convex than in male, frons moderately convex 28
- Male declivity broadly sulcate to rather strongly, broadly concave; male frons less strongly impressed, median elevation absent (except moderately to weakly developed in *knausi*); female declivity usually similarly but usually less strongly impressed, interstriae 1 never elevated; female frons variable but usually somewhat similar to male 30
- 28(27). Pronotum disc with coarse, subcrenulate granules, punctures obscurely evident only near median line, obsolete laterally; male frons below upper level of eyes almost flat, median elevation on vertex moderately developed, little if any higher at its lower end; Mexico (Durango to Michoacan); vine; 1.6–1.9 mm *rudis* Wood
- Pronotum disc with crenulations smaller, punctures clearly evident, obscure but usually present almost to lateral margins; male frons more strongly impressed, median elevation on vertex higher or projecting slightly at its lower end 29
- 29(28). Pronotum disc subreticulate between crenulations, crenulations shorter, thicker, less acutely elevated, more regularly spaced; male frontal impression not as deep, more extensive, elevation on vertex blunt; Panama; vine; 1.5–2.0 mm *confinis* Wood
- Pronotum disc shining, crenulations longer, thinner, more acutely elevated, surface appearing more wrinkled; male frontal excavation deeper, less extensive, elevation on vertex acute; USA (S Utah, S California) to Mexico (Michoacan, Morelia); *Cucurbita*, *Echinocystis macrocarpa*, *Luffa acutangula*; 1.5–2.2 mm *cucurbitae* (LeConte)
- 30(27). Elytral declivity narrower, rather broadly bisulcate, sutural interstriae as strongly elevated as lateral convexities; average size smaller 31
- Elytral declivity broad to very broad, moderately to very strongly impressed, lateral convexities distinctly higher than suture, interstriae 1 not elevated to weakly elevated; average in size 36
- 31(30). Pronotum rather strongly reticulate over entire surface, asperities on anterior half small, rather widely separated, punctures small, most of them subgranulate; interstitial setae rather coarse, blunt; Costa Rica; *Potakowskia tacaco*, *Sechium edule*; 1.5–1.8 mm *declivis* Schedl

- Pronotum rather coarsely asperate and shining on anterior half, rather coarsely punctured or asperate and either shining or partly, obscurely reticulate on posterior half; interstitial setae more slender 32
- 32(31). Larger, stouter; pronotum 1.15 times as long as wide; pronotal and elytral punctures larger, deeper; discal striae almost as wide as interstriae; pronotum shining, entirely devoid of reticulation; declivital strial and interstitial punctures very small; female frons with moderately abundant pubescence 33
- Smaller, more slender; pronotum 1.2 times as long as wide; pronotal and elytral punctures smaller; discal interstriae one and one-half times as wide as striae 34
- 33(32). Elytral declivity more narrowly, more strongly convex; declivital interstriae 2 with a row of small granulate punctures bearing a row of erect setae; female frons weakly convex from epistoma to upper level of eyes, finely, densely punctured, abundant long pubescence extending almost to vertex; Guatemala; 2.3–2.5 mm (see also couplet 21) *limbatus* (Blandford)
- Elytral declivity more strongly, more broadly impressed; declivital interstriae 2 impunctate in both sexes and devoid of a row of interstitial setae; female frons rather strongly convex, punctures much larger, not as close, vestiture long and dense on lower third of area below upper level of eyes, sparse above; Venezuela (Merida); *Cucurbita*; 2.1–2.5 mm *limbellus* Wood
- 34(33). Interstitial setae on disc longer, very fine, pointed, on declivity each seta one and one-half times as long as distance between rows, spaced within a row by distances half as great as distance between rows; strial setae on posterolateral areas fine, more than half as long as interstitial setae; body slender; 3.0 times as long as wide; Mexico (Veracruz) to Costa Rica; vine; 1.7–2.0 mm *macilentus* (Blandford)
- Interstitial setae on disc about as on declivity, blunt, those on declivity as long as distance between rows, spaced within a row by distances slightly less than their length; strial setae very short, almost obsolete; body stouter, about 2.6 times as long as wide 35
- 35(34). Pronotum at least partly reticulate on posterior half in marginal areas or near punctures; transverse granules on pronotum disc finer, not reaching posterior margin; elytral punctures averaging slightly smaller; Mexico (Veracruz) and Honduras to Guadeloupe Island; *Cayaponia microdonta*; 1.7–1.9 mm *guatemalensis* (Hopkins)
- Pronotum shining, devoid of reticulation; transverse granules on pronotum disc coarser, more widely distributed; elytral punctures averaging slightly larger; USA (Florida) to Cuba and Jamaica; 1.6–1.7 mm *carbonarius* (Ferrari)
- 36(30). Interstriae about as wide as striae, strial and interstitial punctures coarse, of equal size and spacing; spine on mesal margin near base of male mandible not evident; pronotum disc shining, punctures coarse, deep; vestiture fine, very long 37
- Interstriae about twice as wide as striae, punctures smaller, more widely spaced; pronotum disc at least partly reticulate in lateral areas, punctures smaller; vestiture much shorter 38
- 37(36). Male frons strongly, transversely impressed from epistoma to upper level of eyes, upper margin rather abrupt, median tubercle on upper margin distinctly larger; male elytral declivity shallowly, rather broadly impressed, interstriae 1 weakly elevated, striae 1 and 2 with punctures shallow to obsolete; female frons more strongly convex above, more coarsely punctured, median tubercle on vertex more conspicuous, a short median carina on lower fifth; Argentina; *Cayaponia ficifolia* *tayuyaensis* Schedl
- Male frons shallowly, transversely impressed from epistoma to upper level of eyes, upper margin gradual, median tubercle small; male elytral declivity broadly, much more strongly impressed, lateral margins rather abruptly rounded, interstriae 1 not elevated, punctures on striae 1 and 2 rather coarse, deep; USA (Kansas to New Mexico); 1.7–2.3 mm *knausi* Hopkins

- 38(36). Male frons more narrowly impressed on median half from epistoma to well below upper level of eyes, with vestiture fine, sparse; female frons more strongly convex, less densely punctured, vestiture sparse, short, inconspicuous; Honduras to Costa Rica; *Cayaponia microdonta*; 2.0–2.9 mm
 **diversus** Wood
- Male frons more strongly, more broadly impressed on median three-fourths from epistoma to upper level of eyes, with moderately abundant, long vestiture extending from epistoma almost to vertex; female frons more broadly convex, more densely punctured below, with a dense brush of abundant, long hair from epistoma to upper level of eyes; Venezuela (Aragua); vine; 2.7–3.2 mm
 **auctus** Wood

Dendrocranulus brasiliensis (Schedl)

Dendrocranulus brasiliensis (Schedl), 1963:224 (*Xylocleptes*). Holotype ♂; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:550)

Diagnosis: Distinguished from all known species of *Dendrocranulus* by the total absence of pronotal asperities; and by the unique frons and elytral declivity described below.

Male: Length 1.9–2.1 mm, 2.8 times as long as wide; color yellowish brown. Frons strongly, abruptly, transversely impressed from epistoma to well above upper level of eyes, lower fifth at epistoma very weakly concave; surfaces shining, punctures minute, rather sparse; vestiture of fine, long, moderately abundant setae; antennal club oval, very slightly longer than wide, slightly longer than scape, sutures 1 and 2 aseptate, obscure, moderately procurved. Pronotum 1.1 times as long as wide; widest at middle of pronotum length, rather weakly arcuate then converging on anterior third to rather broadly rounded, unarmed anterior margin; moderately declivous on anterior fifth; surface smooth, shining, punctures rather coarse, moderately close (separated by half diameter of a puncture), entirely devoid of asperities; vestiture of sparse, moderately long setae on lateral areas. Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures rather small; interstriae shining, with some irregular, fine lines, twice as wide as striae, punctures uniseriate, almost as large as those of striae. Declivity confined to slightly less than posterior third, steep, rather weakly convex; striae 1 and 2 punctured as on disc; interstriae 1 and 3 feebly elevated, 1–7 each with a row of small rounded tubercles, ventrolateral margin subacutely elevated then joining 8 at base of declivity, 7 at base with a very short carinate crest. Vestiture of uniseriate rows of moderately long, erect interstitial setae from base of elytra to apex.

Female: Similar to male except frons broadly flat from epistoma to upper level of eyes, uniformly ornamented by abundant, fine, long setae, apparently, slightly longer at margins; tubercles on declivital interstriae replaced by punctures except on 6–8, crest on 7 slightly longer.

Distribution: Brazil: Nova Teutonia, Santa Catarina 27°11'N, 52°23'W, 300–500 m, *Sapota gonocarpa*, F. Plaumann (type), Malpighiaceae 221 (allotype), *Cassia dalbergia* 74 (male paratype), *Cedrella* 82 (female paratype).

Hosts: Apparently all hosts listed above were roosting (beating) records. The true host should be a Cucurbitaceae vine.

Notes: The above treatment is based on the male holotype, female allotype, 1 male paratype, and 1 female paratype from Brazil.

Dendrocranulus columbianus Schedl

Plate LXXI

Dendrocranulus columbianus Schedl, 1937:167. Holotype ♂; Colombia; NHMW, Wien (References in Wood & Bright c1992:550)

Dendrocranulus limatus Wood, 1974:22. Holotype ♂; Bumbum Forest Station, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:552). *New synonymy*

Diagnosis: Distinguished from *consimilis* Wood by the entire pronotum disc being covered by granules and tubercles, punctures almost entirely absent; and by the slightly larger, stouter body form. The ventrolateral margin of the elytral declivity is subacutely elevated on a continuous costa and the female frons has a brush of long, yellow hair.

Male: Length 1.5–1.7 mm, 2.4 times as long as wide; color reddish brown. Frons convex, a weak transverse impression on lower half of median half, a weak median callus above upper level of eyes; surface shining, punctures organized into obscure convergent aciculation; vestiture sparse, short, hairlike. Pronotum 1.2 times as long as wide; summit at middle, closely, rather coarsely asperate in front, disc rather closely tuberculate, punctures not evident, shining; vestiture hairlike, mostly on anterior and lateral margins. Elytra 1.4 times as long as wide, 1.2 times as long as pronotum; striae not impressed, punctures small, rather deep, very close, interstriae three times as wide as striae, smooth, shining, punctures slightly smaller than those of striae, close. Declivity occupying about 30 percent of elytra length, steep, broadly convex; posterolateral margin from suture to interstriae 7 distinctly, subacutely elevated on a continuous costa; face broadly convex, striae weakly impressed, interstriae 1 distinctly elevated, sculpture about as on disc except punctures feebly granulate. Vestiture consisting of rows of rather stout interstitial setae, each seta very slightly longer than distance between rows.

Female: Similar to male except frons more weakly, broadly convex from epistoma to well above upper level of eyes, this area densely covered by a brush of long, yellow hair; elytral setae slightly more slender.

Distribution: Colombia to Venezuela.

Colombia: "Colombien."

Venezuela: Bumbum Forest Station, Barinas, 29-I-1970, 150 m, No. 276, Cucurbitaceae vine, SLW; 8 km SW Bumbum, Barinas, 11-II-1970, 150 m, No. 311, Cucurbitaceae vine, SLW; 5 km W El Pino, Merida, 20-XI-1969, 10 m, No. 142, Cucurbitaceae vine, SLW.

Biology: Boring in overmature and broken stems of Cucurbitaceae vines.

Notes: The above treatment was based on the 32 specimens in the type series of *limatus* Wood, all from Venezuela. The holotype of *columbianus* Schedl was compared by me directly to paratypes of *limatus*.

Dendrocranulus conditus Wood

Dendrocranulus conditus Wood, 1974:23. Holotype ♂; Bumbum Forest Station, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:550)

Diagnosis: Distinguished from *consimilis* Wood by the reticulate frons and pronotum; by the more narrowly flattened elytral declivity; by the minute to obsolete, sparse interstitial punctures on the disc; and by the more slender interstitial setae.

Male: Length 1.3–1.4 mm, 2.7 times as long as wide; color reddish brown. Frons about as in *columbianus* Schedl, except surface reticulate, aciculation obscure to absent, transverse impression on lower half obscure to absent. Pronotum 1.2 times as long as wide; summit well in front of middle of pronotum length; surface of disc strongly reticulate, punctures rather coarse, deep, most associated with weak, shining rugae; vestiture sparse, restricted to anterior and lateral areas. Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures moderately coarse, deep; interstriae slightly wider than striae, smooth, shining, punctures small, varying from small to obsolete, sparse when present. Declivity steep; striae 1 and 2 distinctly impressed, interstriae 2 distinctly impressed, not as high as 1 or 3, rows of punctures minute but present. Vestiture consisting of interstitial rows of erect, slender, setae on sides and declivity, mostly absent on disc.

Female: Similar to male except short, sparse setae present on frons; declivity less strongly impressed, interstriae 2 not impressed (equal to 1 and 3).

Distribution: Venezuela: Bumbum Forest Station, Barinas, 29-I-1970, 150 m, No. 276, Cucurbitaceae vine, SLW.

Biology: Boring in overmature stems in the Forest Station garden.

Notes: The above treatment was based on the holotype and allotype from Venezuela. The 1 paratype apparently is another species.

Dendrocranulus modus Wood

Dendrocranulus modus Wood, 1979:140. Holotype ♀; Merida, Merida, Venezuela, 1700 m; USNM, Washington (References in Wood & Bright c1992:553)

Diagnosis: Distinguished from *vicinalis* Wood by the absence of reticulation on the pronotum; by the more broadly flattened male frons; and by the larger size.

Male: Length 1.7–2.3 mm, 2.7 times as long as wide; color dark reddish brown. Frons flat on median half from epistoma to upper level of eyes, surface smooth, shining, with very small, sparse punctures; punctures larger and closer at sides and above; vestiture sparse on epistoma and lateral areas. Pronotum 1.1 times as long as wide, obscure summit at middle; asperities on anterior slope small, numerous; rugae in lateral areas attain base; disc on median half rather coarsely, deeply punctured, median line impunctate, surface between punctures smooth, shining, sparse, rather long setae on anterior and lateral areas. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures rather small, deep, close; interstriae almost twice as wide as striae, smooth, shining, punctures small (half as large as those of striae). Declivity steep, broadly convex; interstriae 1 and 2 moderately impressed; punctures on striae 1 and 2 minute, interstriae 1–3 each with a row of fine punctures equal in size to those of adjacent striae. Vestiture of rows of slender interstitial setae on disc and declivity (including interstriae 2 on declivity).

Female: Similar to male except frons more strongly convex above, a moderate transverse impression on lower half; declivity more strongly convex, impression very weak.

Distribution: Venezuela: Merida, Merida, 22-IX-1969, 1700 m, No. 18, *Cucurbita*, SLW.

Biology: Boring in a broken stem of *Cucurbita* sp.

Notes: The above treatment was based on the type series of 18 specimens from Venezuela.

Dendrocranulus costalimai Schedl

Plate LXXI

Dendrocranulus costalimai Schedl, 1938:169. Lectotype, sex?; Santos, Sao Paulo, Brazil; USNM, Washington, designated by Anderson & Anderson 1971:10 (References in Wood & Bright c1992:551)
Dendrocranulus sechii Nunberg, 1972:193. Holotype ♂; Barueri, Sao Paulo, Brazil; MZUSP, Sao Paulo. *New synonymy*

Diagnosis: Distinguished from *modus* Wood by the more strongly convex declivity; by the reticulate pronotum; by the smaller size; and by the darker color.

Male: Length 1.4–1.8 mm, 2.7 times as long as wide; very dark brown to black. Frons broadly convex from epistoma to upper level of eyes, more strongly convex above; a weak median callus from near epistoma almost to vertex, stronger above; surface strongly reticulate, punctures moderately coarse, close, callus impunctate, smooth, shining; vestiture sparse, inconspicuous, hairlike. Pronotum 1.2 times as long as wide; summit anterior to middle of pronotum length, anterior third declivous, rather finely, closely asperate; surface strongly reticulate, punctures on median half of disc very small, each associated with a shining, weak crenulation; sparse vestiture confined to anterior and lateral areas. Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; striae not

impressed, punctures small, moderately deep; interstriae twice as wide as striae, smooth, shining, with a few minute lines, punctures in rows, half as large as those of striae, rather widely spaced. Declivity steep, broadly convex, not impressed, occupying one-fourth of declivity length; sculpture as on disc. Vestiture of interstitial rows of slender, erect setae on sides and declivity; each seta as long as distance between rows.

Female: Essentially as in male.

Distribution: Brazil: Cepec, Bahia, I-III-1981, black-light, Kaston; Santos, Sao Paulo (holotype); Barueri, Sao Paulo, 14-I-1968, *Sechium edule*, K. Lenko (paratypes).

Notes: The above treatment was based on 8 specimens from Brazil, 1 of which was compared by me to Schedl's female cotype of *costalima* Schedl, and on 2 paratypes of *D. sechii* Nunberg (MZUSP).

Dendrocranulus reditus Wood

Plate LXXIII

Dendrocranulus reditus Wood, 1974:23. Holotype ♂; 9 km S Barancas, Barinas, Venezuela, 150 m; USNM, Washington (References in Wood & Bright c1992:553)

Diagnosis: Distinguished from *vinealis* Wood by the more closely, regularly placed punctures on the pronotum disc; by the more strongly impressed male declivity; and by the slightly larger size.

Male: Length 1.3–1.5 mm, 3.0 times as long as wide; color dark reddish brown. Frons broadly, transversely, rather strongly impressed on lower half, a rather prominent, obtuse, median elevation immediately above upper level of eyes; surface shining, punctures sparse, minute on impressed area, larger, closer above; vestiture hair-like, sparse, rather long, inconspicuous. Pronotum 1.1 times as long as wide; summit indefinite, anterior to middle; closely, moderately asperate on anterior slope; disc shining on median third, becoming finely reticulate laterally, punctures fine, each associated with a low, shining, transverse or oblique crenulation; vestiture restricted to anterior and lateral areas. Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; striae not impressed, punctures small, rather deep; interstriae almost twice as wide as striae, surface smooth, shining, punctures in rows, half as wide as those of striae. Declivity restricted to posterior third of elytra length, steep, broadly convex; convex except interstriae 2 weakly impressed, sculpture about as on disc, punctures on 2 present, regularly impressed. Vestiture of rows of erect interstitial setae on disc, sides, and declivity, setae slender, most very slightly longer than distance between rows.

Female: Similar to male, except transverse impression on frons not as strong and median elevation on vertex absent; impression on declivital interstriae 2 much weaker.

Distribution: Venezuela: 9 km S Barancas, Barinas, 1-X-1969, 150 m, No. 34 (and 2-XII 1969, No. 162), vine, SLW; 29 km SW El Vigia, Merida, 10-XII-1969, 50 m, No. 18, Cucurbitaceae vine, SLW.

Hosts: Cucurbitaceae vines.

Biology: Boring in overmature stems.

Notes: The above treatment was based on 97 specimens in the type series, all from Venezuela.

Dendrocranulus pinguis Wood

Plate LXXII

Dendrocranulus pinguis Wood, 1979:140. Holotype ♀; Bumbum Forest Station, Barinas, Venezuela, 150 m; USNM, Washington (References in Wood & Bright c1992:553)

Diagnosis: Distinguished from *securus* Wood by the larger size; by the more strongly, more broadly impressed male frons; by the absence of a median callus on the male vertex; and by the less strongly convex male declivity.

Male: Length 2.2–2.4 mm, 2.5 times as long as wide; color dark reddish brown. Frons moderately, broadly impressed on more than lower half, with no indication of a median elevation above; surface of lower fourth shining immediately above epistoma, then moderately reticulate to well above upper level of eyes, shining area mostly without punctures, reticulate area with moderately abundant, fine punctures; vestiture sparse, hair-like, inconspicuous. Pronotum 1.2 times as long as wide; summit indefinite, at middle; anterior slope moderately, closely asperate; discal area smooth, shining and moderately punctured on median third, becoming weakly reticulate laterally, punctures each with a small, weak, shining crenulation extending transversely; sparse vestiture on anterior and lateral areas. Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures moderately small, deep; interstriae about one and one-half times as wide as striae, smooth, shining, punctures in rows, each at least two-thirds as large as those of striae. Declivity confined to posterior third, steep, broadly, subconvexly impressed from suture to striae 3; interstriae 1 weakly elevated, 2 and most of 3 impressed, lateral convexities slightly higher than suture; interstriae 1–3 each with a row of fine tubercles. Vestiture consisting of rows of erect interstitial setae on disc, sides, and declivity, each as long as distance between rows.

Female: Similar to male except frons more strongly convex, more strongly reticulate, pronotum entirely reticulate; declivity broadly convex, weakly impressed on interstriae 2.

Distribution: Venezuela: Bumbum Forest Station, Barinas, 29-I-1970, 150 m, No. 276, Cucurbitaceae vine, SLW.

Hosts: Cucurbitaceae vine.

Biology: Boring in overmature stems in Forest Station garden.

Notes: The above treatment was based on the type series of 8 specimens from Venezuela.

Dendrocranulus barbatus Schedl

Dendrocranulus barbatus Schedl, 1939:172. Lectotype ♀; Argentina, Vicente Lopez; NHMW, Wien, designated by Schedl 1979:34 (References in Wood & Bright c1992:550)

Diagnosis: Remotely allied to *mexicanus* Wood, but distinguished by the tuft of long hair on the margins of the female oral area; by the longer, more slender interstriae on the elytral declivity; and by the strongly convex female frons that lacks abundant, conspicuous long setae.

Male: Length 2.4–2.6 mm, 2.37 times as long as wide; color very dark brown. Frons convex on upper half and finely, closely punctured, shallowly impressed on lower half; vestiture sparse, inconspicuous. Pronotum 1.1 times as long as wide; sides almost straight and parallel on more than basal half, broadly rounded in front; summit indefinite at middle; anterior slope closely, rather coarsely asperate; posterior areas smooth, shining, a small punctured area behind summit, transverse, rounded rugae continue in lateral areas to base. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures rather coarse, deep; interstriae twice as wide as striae, smooth, shining, punctures uniseriate, almost as large as those of striae. Declivity occupying posterior fourth of elytra length, steep, shallowly impressed on median two-thirds; punctures on striae 1 and 2 rather coarse, deep; interstriae 1 shallowly impressed, 1 weakly, 3 more distinctly elevated, 1, 2, and 3 each with a row of small, rounded tubercles. Vestiture of interstitial rows of long pointed hair, on declivity each seta distinctly longer than distance between rows.

Female: Similar to male, except frons strongly convex above upper level of eyes, closely, deeply punctured, with an impunctate median, longitudinally elongate bulla, moderately, transversely impressed below, with a small, median impunctate area above epistoma; margins of oral area bearing a tuft of long setae; declivital impression not as strong, interstitial tubercles reduced to absent.

Distribution: Argentina: Vicente Lopez, III-1939, *Cayaponia ficifolia*, C. Bruch.

Notes: The above treatment was based on the female lectotype, male lectoallotype, and 1 male and 1 female paratype, all in NHMW, Wien.

Dendrocranulus major Schedl

Dendrocranulus major Schedl, 1938:170. Lectotype ♂; Cochabamba, Bolivia; USNM, Washington, designated by Anderson & Anderson 1971:19 (References in Wood & Bright c1992:552)

Diagnosis: Allied to *limitaris* Wood, distinguished by the larger size and more slender body form; by the wider declivital sulcus; by fewer setae on the frons; and by other characters described below.

Male: Length 2.7 mm, 3.0 times as long as wide; pronotum color almost black, elytra dark reddish brown. Frons moderately convex, a weakly elevated shining median callus slightly above upper level of eyes; mostly rather finely rugose except median line almost smooth, rugose areas with fine moderately abundant setae of moderate length. Pronotum 1.15 times as long as wide; widest on basal third, sides weakly arcuate and subparallel on basal half, rather narrowly rounded in front;

summit indefinite, slightly behind middle of pronotum length; asperities rather small, numerous, confused, their crest becoming rounded toward summit and on lateral areas to base, punctures at and behind summit rather small and each with a weak, rounded lateral crest; sides and asperate area with moderately numerous, rather long, hairlike setae. Elytra 1.8 times as long as wide, 1.8 times as long as wide; disc occupying basal 70 percent of elytra length; striae 1 feebly, others not impressed, punctures rather small, rather strongly impressed; interstriae smooth, shining, about three times as wide as striae, punctures in rows, almost half as wide as those of striae but more widely spaced. Declivity very steep, basically, broadly concave except shallowly impressed from striae 1 almost to 3; punctures on striae 1 and 2 half as large and not as deep as on disc; interstriae 1 distinctly elevated and with a continuous row of very small punctures, 2 distinctly wider than 1 and with a row of punctures on basal fourth and apical fourth (mostly or entirely obsolete on middle half); striae 3 and interstriae 3 each with a row of small punctures, punctures larger than on striae 2. Vestiture mostly confined to sides, shorter and mostly abraded on disc and declivity from suture to striae 3.

Distribution: Bolivia: Cochabamba.

Notes: The above treatment was based on the male holotype.

Dendrocranulus limitaris Wood

Plate LXXII

Dendrocranulus limitaris Wood, 1979:140. Holotype ♀; Rancho Grande, Pittier National Park, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:552)

Diagnosis: Distinguished from *fulgidus* Wood by the less strongly impressed male frons, with only a weak median callus above; by the densely pubescent lower female frons; and by the more broadly, more strongly impressed declivity in both sexes.

Male: Length 1.9–2.3 mm, 2.7 times as long as wide; color dark reddish brown. Frons convex above, weakly, transversely impressed on lower half, an obscure median callus on vertex; surface obscurely reticulate, punctures moderately coarse above, minute below, a few small, rounded granules in central area; vestiture sparse, moderately long, inconspicuous. Pronotum 1.2 times as long as wide; indefinite summit at middle of pronotum length, asperities on anterior slope rather small, close; disc shining, smooth, moderate transverse crenulations extend to base, most crenulations on median third with a small puncture at mesal end; sparse vestiture moderately long on anterior and lateral areas. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; striae 1 feebly, others not impressed, punctures small, rather deep; interstriae twice as wide as striae, smooth, shining, punctures almost as large as those of striae, rather sparse. Declivity restricted to posterior third, steep, broadly impressed (appearing almost transversely flat to

shallowly concave from dorsal aspect); stria punctures small, shallow; interstriae 1 weakly elevated, 2 and median half of 3 moderately impressed; interstriae 1 with a row of fine punctures, 2 impunctate, 3 with a row of fine granules. Vestiture of interstitial rows of fine, long hair, except absent on declivital interstriae 2, each seta about one and one-half times as long as distance between rows.

Female: Similar to male except frons broadly convex from epistoma to vertex, weakly reticulate, moderately, rather coarsely punctured above, finely, densely on lower third, lower third with rather dense, long setae; punctures on discal interstriae more closely spaced; declivity more strongly convex, impressed at striae 1, with 1–3 each with a row of setiferous tubercles.

Distribution: Venezuela: Rancho Grande, Pittier National Park, Aragua, 9-IV-1970, No. 422, Cucurbitaceae vine, SLW.

Biology: Boring in recently cut stems of the host.

Notes: The above treatment was based on the type series of 138 specimens from Venezuela.

Dendrocranulus melaenus (Eichhoff)

Dendrocranulus melaenus (Eichhoff), 1871:136 (*Dryocoetes*). Holotype ♀; America meridionalis (Brazil)

Diagnosis: Two specimens in the BMNH, London, were identified by Sampson (1926:482) as *Dryocoetes melaenus* Eichhoff. Both are males clearly belonging to the genus *Dendrocranulus*. They are distinguished from *limitaris* Wood by the more distinctly, more widely impressed male frons, with a weak median carina above upper level of eyes; female *limitaris* with a dense brush of long, yellow setae above epistoma (female *melaenus* not seen). The elytral setae of *melaenus* are shorter and slightly stouter than in *limitaris*.

Male: Length 1.8–2.0 mm, about 2.6 times as long as wide (glue obstruction, not clear); color dark reddish brown. Frons slightly impressed (planoconvex) on about median three-fourths from epistoma to upper level of eyes, surface smooth, brilliantly shining, punctures sparse, very minute; setae sparse, slender, of moderate length; antennal club oval, sutures 1 and 2 strongly procurved, 1 attaining middle of club length. Pronotum 1.14 times as long as wide; widest slightly behind middle of pronotum length, sides weakly arcuate on basal two-thirds of pronotum length, rather narrowly rounded in front; summit indefinite, anterior to middle of pronotum length; asperities on anterior slope small, numerous, confused, their crest rounded from pronotum summit to base, those from summit to base on and near median line each with a small, deep puncture at mesal end; rather short, hairlike setae of moderate abundance over entire surface. Elytra about 1.7 times as long as wide, 1.7 times as long as pronotum; disc occupying basal 72 percent of elytra length; disc surface smooth, shining; striae not impressed, punctures rather small, in rows, moderately deep; interstriae about as wide as striae, punctures in

rows, each puncture half as large as those of striae (about as in *limitaris*). Declivity rather steep; sutural interstriae feebly elevated, 2 weakly impressed, weakly ascending and broadly rounded from striae 2 to 3; striae and interstitial punctures slightly smaller than those on disc. Vestiture of fine, short, recumbent striae setae from base to apex (many abraded), and erect rows of moderately stout interstitial setae, each seta almost twice as long as those of striae from base to apex.

Distribution: Brazil (FW. Sampson Coll. [accessioned by BMNH] 1926-482).

Notes: Two specimens, cited above, in the BMNH, London, and obtained by them from FW. Sampson, were examined. There are no indications on the labels that these specimens have any standing as types, nor is there an indication that Sampson saw or compared them to the Eichhoff type. They fit Eichhoff's key (1878) and description of *Dryocoetes melaenus* rather well and could be that species. Most *Dendrocranulus* breed in vines of endemic Cucurbitaceae.

Dendrocranulus limbellus Wood

Dendrocranulus limbellus Wood, 1979:139. Holotype ♀; Merida, Merida, Venezuela, 5300 feet; USNM, Washington (References in Wood & Bright c1992:552)

Diagnosis: Distinguished from *limbatus* (Blandford) by the more strongly, more broadly convex elytral declivity, with interstriae 2 impunctate and devoid of setae in both sexes; and by the long, dense vestiture on the lower third of the female frons, similar to *limbatus*.

Male: Length 2.1–2.5 mm, 2.8 times as long as wide; color dark reddish brown. Frons moderately, transversely impressed on median half of lower two-thirds of area below upper level of eyes; weakly reticulate and rather closely, coarsely punctured above, smooth, shining, finely punctured in impressed area below; vestiture of sparse, fine, long hair. Pronotum 1.1 times as long as wide; summit anterior to middle, anterior slope with small, rather close asperities; disc weakly reticulate, median third moderately punctured, a rather small low crenulation extending laterad from each puncture. Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; striae 1 weakly, others not impressed; punctures rather small, close; interstriae three times as wide as striae, smooth, shining, punctures two-thirds as large as those of striae, most spaced by distance equal to width of an interstriae. Declivity broadly, shallowly concave; stria punctures slightly smaller than on disc, rather deep; interstriae 1 weakly elevated at suture, 2 and 3 moderately impressed, punctures on 1 fine, regularly placed, feebly granulate, mostly obsolete on 2 with one granule near base, 3 and 4 with small granules. Vestiture of sparse rows of interstitial setae, most setae as long as distance between rows, a few near base of declivity longer.

Female: Similar to male except frons broadly convex, rather coarsely punctured, lower third and epistoma rather densely covered by long hair; declivity convex, impressed at striae 1, interstriae 1 feebly elevated, with

a row of minute granules, 2 and lower 3 impunctate, upper 3 and lateral areas with a few fine granules.

Distribution: Venezuela: Merida, Merida, 11-IX-1969, 1700 m, No. 1, *Cucurbita*, SLW.

Biology: Boring in a broken stem of the host.

Notes: The above treatment was based on the type series of 27 specimens from Venezuela.

Dendrocranulus tayuyaensis Schedl

Dendrocranulus tayuyaensis Schedl, 1939:173. Lectotype ♀; Vicente Lopez, Argentina; NHMW, Wien, designated by Schedl 1979:250 (References in Wood & Bright c1992:553)

Diagnosis: Distinguished from *knausi* (Hopkins) by the much more strongly impressed male frons; and by the much less strongly impressed male declivity.

Male: Length 1.7–2.0 mm, 2.7 times as long as wide; color very dark reddish brown. Frons strongly, transversely impressed from epistoma to well above upper level of eyes, surface smooth, shining, sparse punctures in lateral areas, part of median line subcarinate; upper margin of impressed area abrupt, crest armed by several small tubercles, median one slightly larger; small spine on inner margin at base of mandible rather small, larger than in *knausi*. Pronotum 1.07 times as long as wide; widest on basal half, sides weakly arcuate, rather broadly rounded in front; summit indefinite, slightly in front of middle of pronotum length, anterior half finely, closely asperate, asperities continuing to base in lateral areas; disc smooth, shining, punctures coarse, transversely connected by weak, rounded rugae; vestiture of sparse hair (abraded on type). Elytra 1.6 times as long as wide; striae 1 feebly, others not impressed, punctures rather small, deep; interstriae twice as wide as striae, punctures two-thirds as large as those of striae, uniseriate, surface smooth, shining, slightly wrinkled. Declivity confined to posterior third of elytra length, steep; shallowly sulcate between left and right interstriae 3, lateral margins broadly rounded, suture weakly elevated; punctures on striae 1 and 2 very small, distinctly impressed, interstitial punctures minute. Vestiture consisting of rows of fine, erect hair from base to apex, most setae equal in length to distance between rows.

Female: Similar to male except frons convex, with fine, irregular rugosity, a weak median carina on lower third, a median callus on vertex; rugae on disc of pronotum larger, more conspicuous; declivity more strongly convex, impression rather weak.

Distribution: Argentina: Vicente Lopez, III-1939, *Cayaponia ficifolia*, C. Bruch (type series).

Notes: The above treatment was based on the female lectotype, male lectoallotype, 1 male and 2 female lectoparatypes from Argentina.

Dendrocranulus auctus Wood

Plate LXX

Dendrocranulus auctus Wood, 1979:139. Holotype; Rancho Grande, Pittier National Park, Aragua, Venezuela; USNM, Washington (References in Wood & Bright c1992:550)

Diagnosis: Distinguished from *diversus* Wood by the larger average size; by the more broadly, more strongly impressed male frons; and by the dense female frontal pubescence extending from the epistoma to the vertex.

Male: Length 2.7–3.2 mm, 2.7 times as long as wide; color dark reddish brown. Frons rather strongly, transversely impressed on lower two-thirds of area below upper level of eyes; surface weakly reticulate above, shining on lower third, dorsal and lateral areas with small to moderately large, rounded granules; vestiture of moderately abundant, fine, long hair from epistoma to well above upper level of eyes. Pronotum 1.2 times as long as wide; summit indefinite, slightly in front of middle; asperities small, close, numerous; disc weakly reticulate, with low, transverse crenulations to base, a small puncture at mesal end of most of those on median fourth; hairlike vestiture mostly on anterior and lateral areas. Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; striae 1 feebly others not impressed, punctures small, moderately impressed; interstriae slightly more than three times as wide as striae, almost smooth, shining, punctures almost as large as those of striae, shallow, regularly spaced, some punctures granulate near declivity on 1–3. Declivity restricted to posterior third, broadly, shallowly concave; striae punctures small to obsolete on 1–4; interstriae smooth, shining, 1 weakly elevated, 2–3 impressed, 4 obtusely subangulate on lower half, 1–3 each with a sparse row of small granules. Vestiture of interstitial rows of erect setae except mostly absent on 2 and 3 on declivity.

Female: Similar to male, except frons broadly, uniformly convex and finely, closely punctate granulate, with a rather dense brush of fine, long hair from epistoma to well above upper level of eyes; disc of pronotum more strongly reticulate; elytral declivity essentially convex, much more narrowly, less strongly impressed, impression deepest at striae 1, striae punctures minute, interstitial punctures on 1–3 replaced by rows of minute granules.

Distribution: Venezuela: Rancho Grande, Pittier National Park, Aragua, 9-IV-1970, 1700 m, No. 407, *Cucurbitaceae* vine, SLW.

Biology: Boring in recently broken stems.

Notes: The above treatment was based on the type series of 50 specimens from Venezuela.

Species Not Seen

Dendrocranulus pilosus Eggers

Dendrocranulus pilosus Eggers, 1943:357. Holotype, sex?; Cochabamba, Bolivia; MNHN, Paris (References in Wood & Bright c1992:553)

Dendrocranulus rubripes (Eggers)

Dendrocranulus rubripes (Eggers), 1943:358 (*Pityophthorus*). Holotype ♂; Cochabamba, Bolivia; MNHN, Paris (References in Wood & Bright c1992:553)

Dendrocranulus uncinatus (Eichhoff)

Dendrocranulus uncinatus (Eichhoff), 1872:134 (*Xylocleptes*). Holotype, sex?; Bogota, Colombia; Hamburg Museum, lost; may belong to another genus (References in Wood & Bright c1992:553)

GENUS *DRYOCOETES* EICHHOFF

Dryocoetes Eichhoff, 1864:38. Type-species: *Bostrichus autographus* Ratzeburg, subsequent designation by Hopkins 1914:121 (Synonymy and references in Wood & Bright c1992:569)

Anodius Motschulsky, 1860:155. Type-species: *Bostrichus autographus* Ratzeburg, subsequent designation by Wood 1974:232, officially suppressed by International Commission on Zoological Nomenclature (ICZN) 1979:149

Dryocoetinus Balachowsky, 1949:180. Type-species: *Bostrichus villosus* Fabricius, original designation

Diagnosis: This introduced genus is not closely related to any South American genus. The relationship to *Dendrocranulus*, *Chiloxylon*, and *Coccotrypes* is remote biologically as well as anatomically. The only known species in South America was introduced from Europe, northern Asia, or North America. It is distinguished by the large size and the coniferous host.

Description: Length 2.8–4.4 mm, 2.5 times as long as wide; color dark reddish brown. Frons broadly convex, rather coarsely punctured, granules rather small; oral region unusually broad. Antennal scape elongate; funicle 5-segmented; club obliquely truncate, basal area corneous, without any sutures on posterior face. Eye oval, emarginate. Pronotum rather evenly, strongly arched from base to anterior margin; anterior slope asperate, asperities often attain base in lateral areas. Elytra with striae weakly impressed, punctures rather coarse, deep; declivity convex, conservatively sculptured. Vestiture hairlike.

Distribution: Wood & Bright (c1992:569–587) list 43 species in the world, mostly in Europe, Asia, and North America. Two additional South American species, cited below, have been referred to this genus, but they appear to belong elsewhere.

Biology: The known species are mainly polygynous and phloeophagous. Although most species breed in the coniferous genera *Abies*, *Larix*, *Pseudotsuga*, *Picea*, *Pinus*, and *Tsuga*, some species infest one or more dicotyledonous Angiospermae. In the dozen or more species observed by me, the beetles enter large limbs or the bole of their host, most commonly at or near the ground level or where limbs lie on the ground. Below the entrance tunnel a nuptial chamber is formed at or just above the cambium area. From this chamber about three to five rather short egg galleries radiate mostly or entirely in the phloem. Eggs are laid in niches, and the larvae develop in the phloem.

Dryocoetes autographus (Ratzeburg)

Dryocoetes autographus (Ratzeburg), 1837:160 (*Bostrichus*). Syntypes, sex?; Sudlichen Deutschland (Hr. Warnkonig) bis Russland und Schweden; presumably at FRI, Muncheberg (Synonymy and references in Wood & Bright c1992:572–576)

Bostrichus villosus Herbst, 1793:121. Syntypes, sex?; Deutscher; not located; preoccupied by Fabricius 1792:367

Bostrichus septentrionis Mannerheim, 1843:298 (reprint p. 126). Syntypes, sex?; Sitka Island, Alaska; MZU, Helsinki, lost, not at Helsinki in 1968

Bostrichus semicastaneus Mannerheim, 1852:358 (reprint p. 76). Holotype, sex?; Sitka Island, Alaska; MZU, Helsinki

Bostrichus victoris Mulsant & Rey, 1853:91. Syntypes, sex?; Faillefeu, Basses-Alpes, France; not located

Dryocoetes americanus Hopkins, 1915:51. Holotype ♀; Cheat Bridge, Randolph County, West Virginia; USNM, Washington

Dryocoetes pseudotsugae Swaine, 1915:360 (reprint p. 5). Lectotype ♀; Stanley Park, Vancouver Island, British Columbia, Canada; CNCI, Ottawa, designated by Bright 1967:674

Dryocoetes alternans Eggers, 1931:30. Holotype, sex?; Sao Paulo, Brazil; NMPC, Prague

Dryocoetes brasiliensis Schedl, 1940:207. Syntypes, sex?; Sao Paulo, Brazil; NHMW, Wien

Dryocoetes longicollis Eggers, 1941:121. Holotype, sex?; Lensahn, Ostholstein; USNM, Washington

Dryocoetes artepunctatus Eggers, 1941:122. Lectotype ♂; Weissrussland (Bialowjesh); USNM, Washington, designated by Anderson & Anderson 1971:4

Dryocoetes sachalinensis Sokanovskii, 1960:675. Syntypes, sex?; Sakhalin Island, Russia; Sokanovskii Collection

Diagnosis: The comparatively large size; very broad oral area; simple, convex elytral declivity; and coniferous hosts will aid in the identification of this species in South America.

Male: Length 2.8–4.4 mm, 2.5 times as long as wide; color dark reddish brown. Frons broadly convex from epistoma to vertex; surface smooth, shining, with rather coarse, deep punctures, their margins weakly granulate; vestiture of sparse long hair except epistomal brush broad, conspicuous. Pronotum 1.1 times as long as wide; anterior two-fifths and lateral areas to base finely asperate, other areas coarsely, deeply, closely punctured, a shining, impunctate area on median line of posterior half often present. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures rather coarse, deep; interstriae smooth, shining, as wide as striae, punctures rather fine, deep, uniseriate. Declivity steep, broadly convex; sculpture about as on disc except interstitial punctures granulate or not; interstriae 1 feebly elevated. Vestiture of rows of fine, short, strial hair and rows of much longer, fine, interstitial hair.

Female: Similar to male except frons with a weak transverse impression just below middle (variable), impunctate at center, remaining area with sparse granules; interstitial punctures with fine granules.

Distribution: Europe, northern Africa, northern Asia, northern North America, introduced into South America.

Brazil: Sao Paulo (Eggers 1931:30, Schedl 1940:207)

Hosts: Known from *Abies*, *Larix*, *Pseudotsugae*, *Picea*, *Pinus*, and *Tsuga* on other continents.

Biology: This species breeds in the basal or stump areas of large trees at or below the ground level. Radiate tunnels usually have 3–5 egg galleries. Larvae develop in the cambium area.

Species Not Seen

Dryocoetes pumilio Eichhoff

Dryocoetes pumilio Eichhoff, 1878:295. Holotype, sex?; America meridionalis, Venezuela; Hamburg Museum, lost (References in Wood & Bright c1992:584)

The original description, cited above, is too general to permit accurate classification of this species. It was described as 1.5 mm in length, very slender, rather dark in color, and rather sparsely pubescent. Eichhoff said it resembled the genus *Xylocleptes*, of Europe (or the nearest South American genus would be *Dendrocranulus*). No attempt was made to associate this species with the members of *Dendrocranulus* treated here.

GENUS *CHILOXYLON* SCHEDL

Chiloxylon Schedl, 1959:550. Type-species: *Chiloxylon rufulus* Schedl, monobasic (References in Wood & Bright c1992:587)

Diagnosis: The type specimen of the type-species of this genus is small, in rather poor condition, and it could very well be placed among primitive Pityophthorina of the Corthylini. In the world key to genera (Wood 1986:73) it is grouped with *Dryocoetiops*, *Ozopemon*, and *Coccotrypes*.

Description: The antennal funicle is 4-segmented; the club is constricted at the partly septate suture 1, suture 2 is indicated by setae (club not actually, obliquely truncate). The protibia is very broad apically; the lateral apical angle is abrupt, about 90 degrees, it has one denticle on this angle, a second denticle on the apical margin, and a third denticle on the lateral margin one-fourth of the tibial length from the lateral apical angle. The general habitus resembles *Dryocoetes*, interstitial setae are almost scalelike on the elytral declivity (Wood 1986:73).

Distribution: Only 1 species has been reported.

Biology: Entirely unknown.

Chiloxylon rufulus Schedl

Chiloxylon rufulus Schedl, 1959:550. Holotype ♂; Mato Grosso: Rio Caraguata; NHMW, Wien (References in Wood & Bright c1992:587)

Diagnosis: Distinguishing features are listed in the generic treatment above.

Original description (Schedl 1959:50): "Rotbraun, 1.8 mm lang, 2.6 mal so lang wie breit.

"Stern über den Augen gewölbt, darunter abgeflacht, mit leichter Eindellung in der Mitte, sehr dicht massig stark punktiert, sehr kurz unscheinbar behaart.

"Halsschild etwas länger als breit (21:19), Basis gerade, hintere Seitenecken rechtwinkelig und wenig gerundet, die Seiten im basalen Funftel nahezu parallel, dann im flachen Bogen trapezförmig verengt, Vorder- und Vorderrand massig breit gerundet, der Länge nach massig gewölbt, in den basalen zwei Dritteln sehr kraftig und sehr dicht punktiert, gegen den Vorderrand werden die Punkte durch kleine Körnchen ersetzt, die ausserdem in konzentrischen Halbkreisen angeordnet sind; Behaarung kurz, rotlich, abstehend. Schildchen sehr klein, knopfförmig, glänzend.

"Flugeldecken wenig breiter (20:19) und 1.5 mal so lang wie der Halsschild, die Seiten bis über die Mitte hinaus parallel, Apex sehr breit gerundet, der Absturz

steil schief gewölbt, relativ kurz, dentlich hinter der Mitte beginnend; die Scheibe wenig glänzend, grob gestreift punktiert, die Reihenpunkte enggestellt, die Streifen deutlich vertieft, die Zwischenräume eng, etwas enger als die Punkstreifen, und jeder derselben mit einer Reihe von Punkten, die in der Nähe der Basis klein sind, gegen den Absturz aber deutlich grösser werden und kurze, abstehende, rotlichgelbe Härchen tragen; auf dem Absturz die Härchen etwas spachtelförmig, die allgemeine Skulpturierung noch etwas rauher und die Punkstreifen stärker vertieft."

Distribution: Brazil: Rio Caraguata, Mato Grosso, IV-1953, F. Plaumann.

Notes: The above treatment was based on notes taken by me at Wien in 1983 and on the original description. The holotype at NHMW, Wien, was examined. The paratype in the Plaumann Collection in Brazil was not seen.

GENUS *COCCOTRYPES* EICHHOFF

Coccotrypes Eichhoff, 1878:308. Type-species: *Bostrichus dactyliperda* Fabricius, subsequent designation by Hopkins 1914:118 (Synonymy and references in Wood & Bright c1992:591-614)

Poecilips Schaufuss, 1897:110. Type-species: *Poecilips sannio* Schaufuss, monobasic

Cryphaloides Formanek, 1908:91. Type-species: *Cryphaloides donis-*

thorpei Formanek = *Bostrichus carpophagus* Hornung, monobasic

Thamnurgides Hopkins, 1915:45. Type-species: *Thamnurgides persi-*

caea Hopkins = *Coccotrypes advena* Blandford, original designation

Spermatoplex Hopkins, 1915:48. Type-species: *Spermatoplex rhizo-*

phorae Hopkins, original designation

Dendrugus Eggers, 1923:144. Type-species: *Dendrugus rhizophorae*

Eggers = *Spermatoplex* Hopkins, subsequent designation by Wood

1982:731

Diagnosis: Distinguished from *Ozopemon* (from SE Asia to Fiji) by the subacutely elevated lateral margins on more than the basal half of the pronotum; anterior half of pronotum declivous or not, asperities present or absent; frons commonly with convergent aciculation; elytral declivity usually convex, rarely impressed (never in South American species), granules absent or inconspicuous; either phloeophagous or spermophagous.

Description: Length 1.2-2.5 mm, 2.1-2.5 times as long as wide; color reddish brown to almost black; sexual dimorphism conspicuous. Males smaller, deformed, flightless, eyes of reduced size, haploid. Frons convex, convergently aciculate in South American species. Eye elongate, finely faceted, shallowly emarginate. Antennal scape slender, elongate; funicle 5-segmented, club somewhat obliquely truncate, with or without sutures on posterior face. Pronotum weakly to strongly arched, smooth to asperate on anterior half. Elytra smooth, shining, striate; declivity convex, simple (in South American species). Tibiae rather slender, armed on lateral margin by 2-4 socketed denticles.

Distribution: Tropical and subtropical areas worldwide. Wood & Bright (c1992:591-614) list 125 species, of which 10 were introduced to South America through commerce. The only native American species appears

DRYOCOETINI

to be *robustus* Eichhoff of Cuba, Puerto Rico, and S Florida (USA).
 Biology: All members of this genus are thought to have male haploidy, and inbreed. Many species are ex-

clusively phloeophagous, others exclusively spermophagous, and at least a few can produce viable offspring in either bark or large seeds.

Key to the Species of *Coccotrypes*
 (Adapted from Wood 1982:732–733)

- 1. Strial setae entirely obsolete, interstitial bristles rather coarse; pronotum usually much more broadly convex both longitudinally and transversely, its anterior margin more broadly rounded and devoid of serrations 2
- Rows of strial setae conspicuously present between rows of longer, fine, interstitial setae; pronotum more strongly, narrowly convex both longitudinally and transversely, its anterior margin more narrowly rounded and partly serrate 4
- 2(1). Pronotum smooth, shining, entirely devoid of asperities, punctures fine, deep, a few of them with one margin minutely granulate; sides of pronotum on anterior third converging rather abruptly; India to Hawaii and Florida to Suriname; fruit and phloem of many hosts; 1.4–2.0 mm *advena* Blandford
- Anterior half of pronotum finely asperate, devoid of punctures in asperate area; sides on anterior third of pronotum broadly rounded; larger species 3
- 3(2). Pronotum asperities fine, more widely spaced, minute to almost obsolete on basal third; surface on posterior half of pronotum etched, subreticulate, shining; strial punctures rather coarse, striae almost as wide as interstriae; Indonesia, S Florida, Mexico (Veracruz), Belize, Galapagos Islands, Peru, Suriname; *Rhizophora mangle* propagules; 2.2–2.5 mm *rhizophorae* (Hopkins)
- Pronotal asperities moderately coarse, close, extending to base, surface between asperities smooth, shining; strial punctures small, interstriae twice as wide as striae; SE Asia to Australia and Hawaii, S Florida and Costa Rica to Suriname and Brazil; phloem and fruits of many hosts; 1.7–2.3 mm *cyperi* (Beeson)
- 4(1). Body rather slender, 2.5 times as long as wide; strial setae erect, almost as long as those of interstriae, both very fine; strial and interstitial punctures equally small, each with a fine granule on anterolateral margin; Cuba to Puerto Rico, S Florida; *Eutrepe globosa*; 1.3 mm *robustus* Eichhoff
- Body stouter, 2.1–2.2 times as long as wide; strial setae semirecumbent, shorter and finer than interstitial setae; strial punctures never with granules on margin 5
- 5(4). Pronotal asperities small, rather sparse, those at summit averaging less than twice as long (transversely) as thick, those at summit as high as those on anterior slope 6
- Pronotal asperities larger, closer, those at summit at least 4 times as long (transversely) as thick, higher on anterior slope than at summit 7
- 6(5). Smaller; interstitial bristles blunt, their apices often slightly flattened, each bristle only slightly longer than distance between interstitial rows; strial punctures small, very shallow, spaced within a row by two or three diameters of a puncture; New Guinea, Costa Rica to Brazil; 1.2–1.3 mm *aciculatus* Schedl
- Larger; interstitial bristles pointed, each about twice as long as distance between interstitial rows; strial punctures shallowly impressed, separated by distances equal to diameter of a puncture; Sri Lanka, Guam to Hawaii, Florida (USA) and Honduras to Suriname; palm fruits; 1.7–2.3 mm ... *distinctus* (Motschulsky)

- 7(5). Body form not as stout, 2.3 times as long as wide; elytral disc proportionately shorter; profile of discal suture more strongly arched, lower half of declivity steeper; striae and interstitial punctures not as close, striae setae minute, half as long; color very dark reddish brown; French Guyane; 2.8 mm *palmarus* Eggers
- Body form 2.2–2.3 times as long as wide; elytral disc proportionately longer, profile of suture straight to feebly convex; declivity more evenly arched, not as steep on lower half; striae and interstitial punctures more closely spaced within a row; striae setae longer, each about half as long as adjacent interstitial setae 8
- 8(7). Smaller; mature color dark brown to almost black; striae punctures very slightly smaller, shallow; interstitial granules on disc averaging smaller, more widely spaced; interstitial setae on declivity shorter, each only slightly longer than distance between rows; almost cosmopolitan through commerce; palm fruits; 1.5–1.9 mm *carpophagus* (Hornung)
- Larger; mature color reddish brown; striae punctures slightly larger, very slightly deeper; interstitial granules averaging slightly larger, closer; interstitial setae on declivity longer, each almost twice as long as distance between rows; almost cosmopolitan through commerce; palm fruits; 1.8–2.3 mm *dactyliperda* (Fabricius)

Coccotrypes advena Blandford
Plate LXXIV

Coccotrypes advena Blandford, 1894:100. Holotype ♀; Nagasaki, Japan; BMNH, London (Synonymy and references in Wood & Bright c1992:591–592)

Thamnurgides persicae Hopkins, 1915:45. Holotype ♀; Honolulu, Hawaii; USNM, Washington (Synonymy and references in Wood & Bright c1992:592)

Dendrugus philippinensis Eggers, 1923:145. Lectotype ♀; Mt. Makiling, Insel Luzon, Philippines; USNM, Washington, designated by Anderson & Anderson 1971:145

Dendrugus ternatensis Eggers, 1923:146. Syntypes ♀; Insel Ternate; MCG, Genova, and USNM, Washington

Dendrugus minor Eggers, 1923:150. Lectotype ♀; Buitenzorg auf Java, Botanischer Garten; USNM, Washington, designated by Anderson & Anderson 1971:21

Thamnurgides setosus Beeson, 1929:228. Holotype ♀; Samoa: Tutuila, Fagasa; BMNH, London

Thamnurgides tutuilensis Beeson, 1929:229. Holotype ♀; Samoa: Tutuila, Fagasa; BMNH, London

Coccotrypes philippinensis Schedl, 1933:104. Holotype ♀; Mount Maquiling, Laguna, Luzon; repository not given

Thamnurgides cubanus Eggers, 1934:79. Holotype ♀; Cuyajabas, Sierra Rosario, Cuba; USNM, Washington

Poecilips nuciferus Schedl, 1938:10. Lectotype ♀; Paramaribo, Suriname; NHMW, Wien, designated by Schedl 1979:172

Thamnurgides vicarius Beeson, 1939:285. Holotype ♀; Samsing, Kalimpong, Bengal, India; FRI, Dehra Dun

Poecilips niger Schedl, 1939:345. Syntypes ♀; Malaya, Selangor: Kuala Lumpur, Kepong, Sungei Buloh For. Res., Perak: Trolak For. Res.; BMNH, London, and NHMW, Wien, preoccupied by Eggers 1927:180

Poecilips subnitidus Schedl, 1954:147. Holotype ♀; Java, Buitenzorg, 250 m; NHMW, Wien

Diagnosis: Pronotum smooth to weakly reticulate, shining, entirely devoid of asperities, punctures present on anterior and posterior areas.

Male: Smaller than female, dwarfed, deformed, flightless.

Female: Length 1.4–2.0 mm, 2.2 times as long as wide; mature color very dark brown. Frons broadly convex,

rather weakly, convergently aciculate on lower third, sparse, fine, granulate punctures above, shining, subreticulate toward vertex; median line broadly, rather indistinctly elevated; vestiture of sparse, fine, long hair. Pronotum 1.06 times as long as wide; widest just behind middle of pronotum length, sides moderately arcuate, converging rather strongly on anterior third, rather narrowly rounded in front; surface smooth and brightly shining to subreticulate (variable in series), finely, rather sparsely punctured, most punctures on anterior half minutely granulate, asperities absent; vestiture of sparse, fine, long hair. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight on basal half, slightly wider near base of declivity, narrowly rounded behind; striae 1 feebly, others not impressed, punctures moderately large, rather shallow; interstriae smooth, shining, about one and one-half times as wide as striae, punctures fine, uniseriate, minutely granulate on their anterior margin. Declivity rather steep, broadly convex; sculpture as on disc. Vestiture of rows of interstitial bristles only; each bristle slightly longer than distance between rows or between bristles within a row; each bristle slender, either slightly flattened on its apical fourth or not.

Distribution: India to Hawaii, and Florida (USA) to Cuba and Suriname.

Suriname: Paramaribo (Schedl 1938:10).

Hosts: Numerous tropical trees, especially those having large seeds.

Biology: This species is able to breed in both bark and the large seeds of numerous host species.

Notes: Wood (1982:733) and Wood & Bright (c1992:592–593) examined the primary types and from them established the synonymy listed above. More than 1000 additional specimens were examined from India, Malaysia, Indonesia, Philippine Islands, Japan, Micronesia, Hawaii, Florida, Cuba, and 1 series from Suriname.

It is expected to spread throughout tropical South America and could become an economic factor in the processing or reproduction of certain fruits and nuts.

Coccotrypes rhizophorae (Hopkins)

Plate LXXXVI

Coccotrypes rhizophorae (Hopkins), 1915:48 (*Spermatoplex*). Holotype ♀; Miami, Florida; USNM, Washington (Synonymy and references in Wood & Bright c1992:609–610)

Dendrugus rhizophorae Eggers, 1923:149. Lectotype ♀; Inslø Saleyer and Moeara Antjol (Sumatra); USNM, Washington, designated by Schedl 1979:211, preoccupied by Hopkins 1915:48

Thamnurgides nephelii Eggers, 1936:84. Holotype ♀; Java (Buitenzorg); BMNH, London

Thamnurgides shanorum Beeson, 1939:296. Holotype ♀; Burma: Northern Shan States, Maymyo; FRI, Dehra Dun

Diagnosis: Distinguished from *cyperi* (Beeson) by the larger average size; by the smaller, more widely spaced asperities on the pronotum; by the smooth, minutely etched to subreticulate surface between the pronotal asperities; and by the larger stria punctures.

Male: Smaller (1.1 mm) than female, dwarfed, deformed, flightless.

Female: Length 2.2–2.5 mm, 2.4 times as long as wide; color reddish brown. Frons essentially as in *advena* Blandford. Pronotum 1.07 times as long as wide; outline about as in *advena*; surface shining, subreticulate; slightly more than anterior half with fine, low, isolated, transverse asperities; posterior area with sparse, minute punctures, most of them minutely granulate or subasperate; vestiture of sparse, fine, long hair. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae weakly impressed, punctures moderately large, rather deep; interstriae smooth, shining, very slightly wider than striae, punctures uniseriate, fine, most of them finely granulate. Declivity rather gradual, broadly convex, more narrowly convex toward apex; sculpture as on declivity except striae 1 slightly more strongly impressed. Vestiture of rows of erect interstitial bristles; each bristle as long as distance between rows, or between bristles within a row, each bristle very slightly flattened on its apical third.

Distribution: Burma to Indonesia and Florida (USA), Mexico (Veracruz), and Belize to Suriname and Peru.

Galapagos Islands: Albermarle Island, 4-14-III-1906, F.X. Williams.

Suriname: “Suriname” (unconfirmed oral reports).

Peru: Timbes, Puerto Pizarro, 18-XI-1996, *Rhizophora mangle*, P.S. Castillo.

Hosts: *Rhizophora mangle*, *R. mucronata*, and (in Indonesia) *Nephelium lappaceum*.

Biology: The living propagules (“fruits”) dropped by the parent plants are attacked, and destroyed. The destruction of mangrove reproduction in some areas is said to be so complete that the character of the coastal mangrove forests is deteriorating rapidly, threatening to seriously erode coastal areas. So far as is currently known

in South America, only the mangrove (*Rhizophora* spp.) trees are affected.

Notes: The above treatment was based on my series from Burma, Indonesia, Hawaii, Florida, Mexico (Veracruz), Belize, Galapagos Islands, and Peru. The holotypes of *Spermatoplex rhizophorae* Hopkins, *Thamnurgides nephelii* Eggers, and *Thamnurgides shanorum* Beeson, and the lectotype of *Dendrugus rhizophorae* Eggers were examined and compared to my series.

Coccotrypes cyperi (Beeson)

Plate LXXXV

Coccotrypes cyperi (Beeson), 1929:230 (*Thamnurgides*). Holotype ♀; Upalo: Apia, Samoan Islands; BMNH, London (Synonymy and references in Wood & Bright c1992:598–599)

Thamnurgides indicus Eggers, 1936:631. Holotype ♀; Sakalapur, Mysore States, India; BMNH, London

Xyleborus conspiciens Schedl, 1936:110. Holotype ♀; Hamburgfarm, Rio Reventazon, Limon, Costa Rica; NHMW, Wien

Dryocoetes insularis Eggers, 1940:127. Syntypes ♀; Guadeloupe and Martinique; MNB, Berlin, 4 cotypes in NHMW, Wien, preoccupied by Eggers 1939:223

Coccotrypes insularis Eggers, 1940:129. Lectotype ♀; Trois-Rivieres, Guadeloupe; USNM, Washington, designated by Anderson & Anderson 1971:15, preoccupied by Eggers 1939:223

Dryocoetes subimpressus Eggers, 1940:127. Holotype ♀; Trois Rivieres, Guadeloupe; NHMW, Wien [this name inadvertently, incorrectly spelled *subdepressus*, a lapsis calami]

Poecilips subaplanatus Schedl, 1942:23. Lectotype ♀; O. Preanger, Tjampea, Java; NHMW, Wien, designated by Schedl 1979:240

Poecilips caraibicus Schedl, 1952:345. Syntypes ♀; Guadeloupe and Martinique; MNB, Berlin, and USNM, Washington

Poecilips eggersi Schedl, 1952:347. Lectotype ♀; Trois-Rivieres, Guadeloupe; USNM, Washington, designated by Anderson & Anderson 1971:15

Poecilips pilifrons Browne, 1970:568. Holotype ♀; Nilgiri Hills, Indis; BMNH, London

Diagnosis: Distinguished from *rhizophorae* (Hopkins) by the smaller average size; by the larger, more closely spaced asperities on the pronotum, with the spaces between asperities smooth, shining; by the smaller stria punctures; and by the very different habits.

Male: Smaller (1.1–1.2 mm) than female; dwarfed, deformed, flightless, eye reduced or absent, haploid.

Female: Length 1.7–2.3 mm, 2.3 times as long as wide; rather dark reddish brown. Frons broadly convex, convergently, rather finely aciculate from epistoma to upper level of eyes, with fine, rather deep punctures interspersed, rugose-reticulate above; vestiture of sparse, fine hair. Pronotum 1.08 times as long as wide; outline as in *advena* (Blandford); surface smooth, shining, rather closely, somewhat coarsely asperate to base, those on posterior half decreasing in size, a few punctures interspersed near base of disc; vestiture of sparse, fine, hair, usually abraded. Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures small, shallow; interstriae smooth, shining, twice as wide as striae, punctures uniseriate, fine, minutely granulate. Declivity rather steep, convex; sculpture as on disc. Vestiture of rows of erect, blunt, interstitial

bristles; each bristle about one and one-half times as long as distance between rows or between bristles within a row, each very slightly flattened at extreme tip.

Distribution: India and S China to Australia, and Hawaii, Jamaica, Costa Rica, Trinidad, Suriname, and Brazil.

Brazil: Amazonas, Manaus, INPA Campus, ethanol trap, R.L.S. Abreu; Seropedica, Rio de Janeiro, UFRRS Campus, atrophied Atlantic forest, ethanol trap, A.M. Lunz; Maranhao, Pedriman edo Luis Island, white tray trap, E.C. Bergman; Sao Paulo, Agudos, Duraflora, ethanol trap, *Pinus oocarpa* stand, C.A.H. Flechtmann; Sao Paulo, Ifapetininga, ESALQ-84, 11-X-1991, ethanol trap, *Pinus elliottii* stand, A. Dwulatka; MS, Tres Lagoas, CPC, Horto Barra do Moeda, 2-XI-1993, ethanol trap, C.A.H. Flechtmann.

Suriname: "Suriname" (Wood 1982:735, Wood & Bright c1992:598).

Hosts: *Aesculus punchuana*, *Amoora walichii*, *Artocarpus lakoocha*, *Borassus flabellifer*, *Canarium strictum*, *Carallia lucida*, *Careya arborea*, *Cossia arabica*, *Cynometra hemitobophylla*, *Diptocarpus trinervis*, *Eleocarpus oblongus*, *Eugenia formosa*, *E. sp.*, *Ficus glomerata*, *Gluta travancoria*, *Macademia indica*, *Macaranga denticulata*, *Mammea americana*, *Mangifera indica*, *Orbignya oleifera*, *Persea americana*, *Phytellephas macrocarpa*, *Pronia copaifer*, *Swietenia macrophylla*, *Swintonia floribunda*, *Terminalia myriocarpa*, *Theobroma cacao*, *Vateria indica*, *Xylia dolabriformis*. (This is a world-wide host list).

Biology: Common on the forest floor in large seeds of fallen fruit. It is reported to breed in bark in Burma and Malaysia but has not been seen in bark by me in American forests. Previously mated females enter a fallen fruit and form a short cave tunnel, usually in a large seed, where eggs are deposited in clusters. The larvae extend or enlarge the parent tunnel, often consuming the entire seed. Larval development is very rapid. Mating is normally among siblings in the brood chambers, often, unsclerotized white males were observed to mate repeatedly.

Notes: The above treatment was based on several hundred specimens taken in Costa Rica and Panama, on 1 series from Suriname, and on several specimens from Brazil. Part of these were compared directly by me to the type series of *cyperii*, *indicus*, *conspiciens*, *insularis* (1940:127), *insularis* (1940:129), and *impressus*. The name *subdepressus* was used by Eggers for this species, but this name has never been validated in nomenclature.

Coccotrypes aciculatus Schedl

Plate LXXIII

Coccotrypes aciculatus Schedl, 1952:360. Holotype ♀; Hamburgfarm on Rio Reventazon, Limon, Costa Rica; NHMW, Wien (References in Wood & Bright c1992:591)

Diagnosis: Distinguished from *distinctus* (Motschulsky) by the much smaller size; by the blunt, apically flat-

tened, shorter interstitial bristles; and by the smaller, very shallow, rather widely spaced striaal punctures.

Male: Length 1.0 mm (described by Schedl 1950:148). Not seen by me.

Female: Length 1.2–1.3 mm, 2.0 times as long as wide; color reddish brown. Frons about as in *distinctus*. Pronotum 1.0 times as long as wide; widest just behind middle, sides moderately arcuate, converging on anterior half to rather broadly rounded, subserrate anterior margin; strongly convex, with indefinite summit slightly behind middle of pronotum length; asperities on anterior slope small, sparse, intermixed with sparse, fine, shallow punctures; small, sparse subasperate granules on posterior area to base; surface smooth, shining; an obscure, raised basal line indicated; vestiture of sparse, blunt hair of moderate length. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures moderately small, distinct, very shallow, spaced within a row by about two to three diameters of a puncture; interstriae about twice as wide as striae, smooth, shining, punctures replaced by small, uniseriate, widely spaced granules. Declivity moderately steep, rather broadly convex; sculpture essentially as on disc. Vestiture of short, fine striaal hair and rows of erect, blunt interstitial bristles, each bristle as long as distance between rows or between bristles within a row.

Distribution: New Guinea at Erima, Astrolobe Bay (Schedl 1955:281), and Costa Rica and Panama to Brazil.

Brazil: Brazil ex Cumala nut, 5-X-1938 (Schedl 1950:148); Camboriu, Parque Unipraias, Santa Catarina, 31-XII-2001, Atlantic forest, *Cecropia* petiole, C.A.H. Flechtmann; Argudos, Sao Paulo, 16-XII-1986, Duraflora forest, ethanol trap, *Pinus oocarpa* and *P. caribea hondurensis* stand, C.A.H. Flechtmann; Sao Paulo, Lencois Paulis, ca Duraflora, ethanol trap, *Eucalyptus grandis* stand, C.A.H. Flechtmann.

Hosts: Cumala nut.

Biology: Boring mainly in palm and cecropia petiole seeds.

Notes: The above treatment was based on the holotype from Costa Rica, on 1 female from Panama, and on 1 female from Brazil.

Coccotrypes distinctus (Motschulsky)

Plate LXXVI

Coccotrypes distinctus (Motschulsky), 1866:403 (*Anodius*). Holotype ♀; type labeled Ceylon, published as Des Montagnes de Nura-Ellia; IZM, Moscow (Synonymy and references in Wood & Bright c1992:602)

Coccotrypes floridensis Schedl, 1948:117. Lectotype ♀; Winter Park, Florida (USA); NHMW, Wien, Schedl 1979:98

Diagnosis: Distinguished with difficulty from some *carpophagus* (Hornung) by the small, isolated asperities on the pronotum disc, none more than twice as long as thick; color reddish brown (never black).

Male: Smaller (1.3 mm), dwarfed, deformed, flightless.

Female: Length 1.7–2.3 mm, 2.2 times as long as wide; color reddish brown. Frons about as in cyperi Beeson. Pronotum 1.0 times as long as wide; about as in *aciculatus* Schedl except asperities smaller (on both disc and anterior slope), much shorter, each about twice as long as thick, rather widely separated from one another; setae finer, slightly longer. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; striae not impressed, punctures rather small, distinctly impressed, separated within a row by diameter of a puncture, interstriae about three times as wide as striae, smooth, shining, punctures replaced by small, widely spaced, uniseriate granules. Declivity steep, convex; sculpture as on disc. Vestiture of rows of semirecumbent strial hair, each half as long as distance between rows; and rows of erect, fine, pointed interstitial bristles, each bristle slightly shorter than distance between rows or between bristles within a row.

Distribution: Sri Lanka, New Guinea to Hawaii, S USA, Honduras, Puerto Rico and Jamaica to Suriname and Guiana.

Brazil: Agudos, Sao Paulo, 5-II-1985, Duraflora SA forest, ethanol trap in *Pinus caribea hondurensis* stand, C.A.H. Flechtmann.

Guiana: “British Guiana” (Wood 1982:737).

Suriname: “Suriname” (Wood & Bright c1992:602).

Hosts: *Coccothrinus* sp., *Phoenix* spp. palms.

Biology: Boring in palm fruits and seeds.

Notes: The female holotype was examined in 1968 at a time when other specimens were not available for direct comparison. Also examined were Schedl’s specimens from Guam he reported as *carpophagus* (Hornung) and the holotype of *floridensis* Schedl.

Coccotrypes rutschuruensis Eggers (?)

Coccotrypes rutschuruensis Eggers, 1940:103. Holotype ♀; Congostaat, Rutshuru; MRCB, Tervuren (References in Wood & Bright c1992:611)

Coccotrypes surinamensis Schedl, 1948:116. Lectotype ♀; Suriname (=Dutch Guiana); NHMW, Wien, designated by Schedl 1979:247 (References in Wood & Bright c1992:613). Probable synonym, see below

Coccotrypes brevipilosus Eggers, 1951:150. Holotype ♀; Blumenau, Brazil; NHMW, Wien, preoccupied by Beeson 1939:298

Diagnosis and discussion: The entity treated here may be (1) a composite of 2 or more species, or (2) a single species represented by 2 or more introductions that have been modified through hybridization. DNA studies or the collection of many more series will probably be needed to resolve the problem. The body is smaller (1.5–2.0 mm) and more slender (elytra 1.3 times as long as wide) than in *distinctus* (Motshulsky); the pronotum is about as in *carpophagus* (Hornung) except the discal area is mostly smooth and shining and has the crenulations sparse and very short as in *distinctus*. The interstitial setae are sparse and short as in *distinctus*. One series, from “Italian” Somalia (Africa) appears to be *rutschuruensis* Eggers (compared directly to a cotype by me); a second series is from Suriname, ex *Astroca-*

cyrum, 1948, and appears to have been part of the topotypic series taken with the lectotype of *surinamensis* Schedl; the third series is from Brazil (Sao Paulo, Agudos, Duraflora, ethanol trap in *Pinus caribaea caribaea* stand, C.A.H. Flechtmann); a fourth series was taken in California (Wood & Bright c1992:611).

All 4 series before me are different from one another and, in the above key, had been placed with *distinctus*, a very different species.

Distribution: Ghana, Somalia, Zaire (in Africa); California (USA), Brazil, and Suriname.

Brazil: Sao Paulo, Agudos, Duraflora, ethanol trap in *Pinus caribaea caribaea* stand, C.A.H. Flechtmann; “Brasil (Blumenau).”

Suriname: “Dutch Guiana,” 1948, ex *Astrocaryum murumura* palm nut (Schedl 1948c:116).

Notes: The above treatment was based on the 5 series described above.

Coccotrypes palmarus Eggers

Coccotrypes palmarus Eggers, 1933:8. Holotype ♀; French Guyane (Haut-Carsevenne); MNHN, Paris (Wood & Bright c1992:608)

Diagnosis: Distinguished from *carpophagus* (Hornung) and *dactyliperda* (Fabricius) by the stouter body form; by the shorter elytral disc, with the profile of the suture more strongly arched and the lower declivity steeper; strial and interstitial punctures not as close, strial setae minute, half as long; color dark reddish brown.

Female: Length 2.8 mm, 2.3 times as long as wide; color very dark reddish brown. Frons strongly convex, shining, distinctly, shallowly, convergently aciculate from epistoma to above upper level of eyes, punctures obsolete; vestiture of rather sparse, moderately long, hairlike setae. Pronotum 1.0 times as long as wide; sides rather strongly, evenly arcuate on more than basal two-thirds, narrowly rounded in front; anterior margin armed by 8 rather coarse serrations; summit slightly behind middle of pronotum length; anterior slope steep, aperiodities rather coarse, close, confused, some of those near summit up to four times as wide as thick; posterior areas mostly smooth, shining, punctures replaced by rather small granules spaced by 1–3 diameters between granules; hairlike setae rather numerous, rather long over entire surface. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; disc occupying basal 54 percent of elytra length, profile of disc moderately arched (slightly more than on declivity); surface smooth, shining, striae not impressed, punctures rather small, larger and deeper than in *carpophagus* and more widely spaced; interstriae about three times as wide as striae, punctures small, about one-third as wide as those of striae. Declivity steep, broadly convex except almost flat on median half, profile of suture feebly convex; centers of punctures on striae 1 and 2 mostly with a small granule at center (somewhat oculate); lateral crest at 3 broadly rounded, feebly higher than suture. Vestiture of short strial setae at least on

declivity, and interstitial rows of slender, erect setae equal in length to 1.5 times width of an interstriae.

Distribution: French Guyane: Haut-Carsevenne, 1899, F Geay.

Notes: The above treatment was based on the female holotype and 1 female paratype bearing identical labels. Two larger species in my collection, from Africa, very closely resemble *palmaris*. It is probable that *palmaris* was introduced to South America prior to 1900.

Coccotrypes carpophagus (Hornung)

Plate LXXIV

- Coccotrypes carpophagus* (Hornung), 1842:116 (*Bostrichus*). Syntypes ♀; Ostindien in Furchten von Betelnüssen; MNB, Berlin (Synonymy and references in Wood & Bright c1992:594–597)
- Coccotrypes pygmaeus* Eichhoff, 1878:310. Syntypes ♀; Madagascar; NHMW, Wien
- Coccotrypes integer* Eichhoff, 1878:331. Syntypes ♀; Siam; 1 in USNM, Washington, others lost with Hamburg Museum
- Cryphaloides donisthorpei* Formanek, 1908:91. Syntypes ♀; Kew Gardens, London, England; BMNH, London
- Coccotrypes bakeri* Hopkins, 1915:46. Holotype ♀; Havana, Cuba; USNM, Washington
- Coccotrypes anonae* Hopkins, 1915:46. Holotype ♀; Cuba; USNM, Washington
- Coccotrypes hubbardi* Hopkins, 1915:46. Holotype ♀; Monserrat, West Indies; USNM, Washington
- Coccotrypes thrinacis* Hopkins, 1915: 46. Holotype ♀; Isle of Pines, Cuba; USNM, Washington
- Coccotrypes liberiensis* Hopkins, 1915:47. Holotype ♀; Mount Coffee, Liberia; USNM, Washington
- Coccotrypes rollinae* Hopkins, 1915:47. Holotype ♀; Para, Brazil; USNM, Washington
- Coccotrypes nanus* Eggers, 1920:33. Lectotype ♀; Cameroon; USNM, Washington, designated by Anderson & Anderson 1971:21
- Coccotrypes canariensis* Eggers, 1928:117. Lectotype ♀; Gran Canaria (Las Palmas) im Park Santa Catalina; USNM, Washington, designated by Anderson & Anderson 1971:8
- Coccotrypes phoenicola* Beeson, 1939:281. Holotype ♀; United Provinces, India; FRI, Dehra Dun
- Coccotrypes trevori* Beeson, 1939:282. Holotype ♀; Nicobars: Kondul; FRI, Dehra Dun
- Coccotrypes pilosulus* Schedl, 1948:118. Holotype ♀; Kurando, Q. (Queensland?); NHMW, Wien
- Coccotrypes ceylonicus* Schedl, 1948:119. Lectotype ♀; Ceylon; NHMW, Wien, designated by Schedl 1979:55
- Coccotrypes punctulatus* Eggers, 1951:151. Holotype ♀; Insel St. Thomas, Virgin Islands; NHMW, Wien
- Coccotrypes grisseopuberulus* Schedl, 1972:59. Holotype ♀; Pariquera, Sao Paulo, Brazil; NHMW, Wien
- Coccotrypes exasperatus* Schedl, 1975e:455. Holotype ♀; Madras: Anaimalai Hills, au dessus d'Aliyar Dam; MHCG, Genebe

Diagnosis: Distinguished from *dactyliperda* (Fabricius) by the smaller size; by the darker color; by the smaller average size of the stria punctures and of the discal interstitial granules; and by the shorter interstitial bristles.

Male: Smaller (1.2–1.3 mm), dwarfed, deformed, flightless.

Female: Length 1.5–1.9 mm, 2.2 times as long as wide; color very dark brown to almost black. Frons broadly convex, weakly, transversely impressed on lower half; about as in *distinctus* (Motschulsky). Pronotum resembling *distinctus* except anterior margin rather coarsely serrate; asperate to base, asperities rather coarse, close,

abundant, those behind summit with long axis longitudinal, each about 4–6 times as long as thick; punctures not evident; vestiture of rather sparse hair of moderate length. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; about as in *distinctus*. Vestiture of rows of short, recumbent stria hair; and rows of erect interstitial bristles, each bristle slender, blunt, very slightly longer than distance between rows of setae or between bristles within a row.

Distribution: Cosmopolitan through commerce, breeding only in tropical and subtropical areas where the hosts grow from S Europe and S Asia to Africa and Australia; New Jersey (USA) to Brazil.

Brazil: Para; Manaus, Amazonas, Adolpho Ducke Forest Reserve, 10-V-1993, ethanol trap, RLS Abreu; Pedrinhas; Seropedica, UFFRS Campus, Rio de Janeiro, 28-XII-2000, *Pinus* stand, ethanol trap, A.M. Llunz; Tres Lagoas, International Paper, Horto Rio Verde, Mato Grosso do Sul, 7-IV-1999-4-V-2003, carrado stand, ethanol trap; MA, Sao Luis Island, 7-VII-1987, white tray trap, E.C. Bergmann; Tres Llagos, MS, CPC, Horto Barra do Moeda, 25-III-1995, 18-V-1995, ethanol trap, *Eucalyptus grandis* stand, C.A.H. Flechtmann; Morretes, PR, 27-VII-1982, sementes palmito, Pedrosa; Telmaco, Borba, PR, KPC, 22-III-1996, ethanol trap, *Eucalyptus grandis* stand, C.A.H. Flechtmann; Agudos, Duraffora, SP, 2-IX-1980, 30-XII-1986, ethanol trap, *Pinus* spp. stand, C.A.H. Flechtmann; Parquergcu, palmeto, A.A. Martines.

Colombia: Palmira, 1-VII-1942, B.L. Losada.

French Guyane: Cayenne (Wood & Bright c1992:594).

Guiana: Guiana (Wood & Bright c1992:594).

Peru: Peru (Wood & Bright c1992:594).

Suriname: Suriname (Wood & Bright c1992:593).

Hosts: *Anona squamosa*, *Archantophoenix alexandrae*, *Areca catechu*, *Borassus flabellifer*, *Cassia grandis*, *Chamaedorea elegans*, *Chrysalidocarpus* sp., *Coccothrinix argentea*, *Diospyros* spp., *Elaeis guineensis*, *Erythrina cyiestagalli*, *Eugenia cumini*, *Euterpe globosa*, *Hyphaena guineensis*, *Livingstonia* spp., *Manikara kauki*, *Neowashingtonia robusta*, *Phoenix dactylifera*, *Polyalthia simiarum*, *Prichardia thurstoni*, *Rollinia octopetala*, *Sabal mauretiaeformis*, *S. palmetto*, *Shorea robusta*, *Theobroma cacao*, *Thrinax argentinia*, *Washingtonia filifera*. This host list is worldwide.

Biology: This species has been transported through commerce almost worldwide in palm nuts and other large seeds of many kinds.

Notes: The above treatment was based on several thousand specimens, mostly from Puerto Rico and Central America to Brazil. The types of all of the synonyms were examined and compared to my series.

Coccotrypes dactyliperda (Fabricius)

Plate LXXV

- Coccotrypes dactyliperda* (Fabricius), 1801:387 (*Bostrichus*). Syntypes 2 ♀ ♀; date seeds; UZMC, Copenhagen (Synonymy and references in Wood & Bright c1992:599–602)
- Bostrichus palmicola* Hornung, 1842:116. Syntypes ♀; Ostindien, Fruchten von Betelnüssen; MNB, Berlin

Coccotrypes tropicus Eichhoff, 1878:312. Holotype ♀; America meridionalis, Peru; Hamburg Museum, lost
Coccotrypes laboulbenei Decaux, 1890:2 (p. 1–16). Syntypes, sex?; Siam; not located
Coccotrypes eggersi Hagedorn, 1904:449. Syntypes ♀; Hamburg importiert in Steinnussen aus Ekuador; Hamburg Museum, lost
Coccotrypes bassivorus Hopkins, 1915:47. Holotype ♀; Washington, D.C.; USNM, Washington
Coccotrypes moreirai Eggers, 1928:86. Lectotype ♀; Guaxupe Minas Garaes, Brazil; USNM, Washington, designated by Anderson & Anderson 1971:21
Coccotrypes tanganus Eggers, 1935:307. Holotype ♀; Ostafrika (Tanga); BMNH, London
Coccotrypes borassi Beeson, 1939:283. Holotype ♀; Coorg; Bhagamandala; FRI, Dehra Dun
Coccotrypes elaeocarpi Beeson, 1939:284. Syntypes ♀; Bhagamandala, Coorg, India, 3500 ft.; FRI, Dehra Dun

Diagnosis: Distinguished from *carpophagus* (Hornung) by the larger size; by the lighter color; by the deeper and slightly larger stria punctures; and by the longer interstitial bristles.

Male: Smaller than female, dwarfed, deformed, flightless.

Female: Length 1.8–2.3 mm, 2.3 times as long as wide; color rather pale reddish brown. Frons about as in *carpophagus*. Pronotum about as in *carpophagus* except anterior margin less coarsely, less regularly serrate, asperities more numerous, each smaller in basal area but averaging as high or slightly higher. Elytra 1.3 times as long as wide; as in *carpophagus* except stria punctures averaging slightly larger, distinctly deeper; interstitial bristles more slender, pointed, each about one and one-half to two times as long as distance between rows, more closely spaced within a row.

Distribution: Cosmopolitan through commerce, breeding only in tropical and subtropical areas where the hosts grow from S Europe and S Asia to Africa and Australia; California and Florida (USA) to N Argentina.

Argentina: “Argentina” (Wood & Bright c1992:599).

Brazil: Minas Garaes Guaxupe Araraquara, Sao Paulo, EEIF, 27-IX-1988, *Acrocomia aculeata* seeds, E.P. Teixeira; Araraquara, SP, EEIF, 27-IX-1988, *Acrocomia aculeata* seed, E.P. Teixeira.

Chile: “Chile” (Wood & Bright c1992:601–602).

Colombia: “Colombia” (Wood & Bright c1992:602).

Ecuador: Intercepted at Hamburg in nuts received from Ecuador.

Guiana: “Guyana” (Wood & Bright c1992:602).

Peru: Jenaro Herrera, 6-VI-1990, *Astrocaryum* fruit, Couturier; America meridionalis (Peru).

Uruguay: “Uruguay” (Wood & Bright c1992:599).

Venezuela: “Venezuela” (Wood & Bright c1992:599).

Hosts: *Acrocomia aculeata*, *Areca catechu*, *Astrocaryum murumura*, *Cargotus urenus*, *Chamaedorea* spp., *Cargotus urenus*, *Chamaedorea* spp., *Chamerops* spp., *Cinnamomum zeylanicum*, *Coccus* spp., *Coccothrinax* sp., *Dictyospermum album*, *Elaeis guineensis*, *Elaeocarpus oblongus*, *Freycinetia arborea*, *Hyphaena* spp., *Hyphorbe* sp., *Livingstonia* spp., *Olea europaea*, *Oreodoxa* spp., *Persea gratissima*, *Phoenix* spp., *Phytelaphas macrocarpa*, *Pritchardia pacifica*, *Pitychosperma* sp., *Sabal bermudana*, *Seaforthia* sp., *Washingtonia filifera*, and many others (see Schedl 1961k:698–701 for African additions).

Biology: Large seeds, particularly of palms, are selected for attack. It commonly infests buttons made from vegetable ivory even when they are polished and painted. Virgin females are capable of establishing a new gallery, then producing parthenogenetically 2 or 3 haploid males, with whom she then mates in order to produce diploid females.

Notes: The above treatment was based on the original type material of *Bostrichus dactyliperda* Fabricius, *B. palmicola* Hornung, *Coccotrypes bassivorus* Hopkins, *C. moreirai* Eggers, *C. tanganus* Eggers, *C. borassi* Beeson, and *C. elaeocarpi* Beeson. The others were either lost or could not be located, and their synonymy was based on the observations of Eggers and/or Schedl.

TRIBE XYLEBORINI

Description: Body dimorphic, male usually dwarfed, modified, flightless, eye reduced in size, its shape often aberrant, and haploid; female normal, diploid. Frons convex, unadorned; eye emarginate to divided (Asiatic species only); antennal scape elongate, funicle 5-segmented (some Asiatic genera 3- or 4-segmented), club obliquely truncate (basal corneous area reduced or absent in some genera). Pronotum variously asperate on anterior slope (asperities absent in some males); procoxae varying from contiguous to widely separated; scutellum varying from large and flat to modified to absent. Elytra variable, conservatively to elaborately sculptured. Protibia variable; meso- and metatibiae flat, broad, tapered on apical third, lateral margin armed by a row of numerous, small, closely set socketed denticles, these usually alternating with marginal or submarginal setae in specialized groups; meso- and metatarsi retractable into tibial grooves.

Biology: Xylomycetophagy and inbreeding polygyny are universal in this tribe. Males are rare, haploid, and are produced only from unfertilized eggs; modified. Mating usually occurs among siblings in the brood chamber. Eggs are deposited in clusters in the parent tunnels. The larvae usually extend the parent galleries and feed almost exclusively on the fungal growth that is cultivated on the walls in these tunnels. Only in *Xyleborinus andrewesi* (Blandford), from tropical Asia, have partial, individual larval mines been reported. The brood emerges through the parent entrance hole. Temperate species may overwinter either in the brood host or in litter on the forest floor. Several species in several gen-

era have been transported through commerce to and from South America.

Notes: Because the species of Xyleborini are so poorly known in South America and comprise a significant portion of the fauna of that area, the limited material reported here does not fairly report the geographical or host ranges of the existing endemic species. For this reason, it was considered prudent to include in the identification keys almost all species reported from both North and South America. The descriptive treatment, however, is restricted to species actually occurring in and reported from South America. A few Central American and Mexican species new to science are also treated. The inbreeding mating system found in all Xyleborini makes these species capable of producing haploid males by parthenogenesis. These males may then mate with their own mothers or female siblings to produce diploid females and, thus, establish a breeding population from 1 introduced female, virgin or not. The ease and speed with which such populations can be established was a significant concern in determining what should and should not be included in this volume. It was noted in a preliminary count that 21 of 174 species (12 percent) of the Xyleborini species reported below were either introduced to South America or have been exported through commerce to other parts of the world. The potential for economic impact by these species is obvious. *Xyleborus abberrans* Schedl, named from Sri Lanka (Ceylon), was reported by Schedl (1971:148) from Brazil, Sete Lagos; if it was correctly identified, it was regarded as an interception, not as a resident species.

Key to the Genera of Xyleborini
(Females only. Adapted from Wood 1986:79–82)

- 1. Basal segment of labial palpus cylindrical, only slightly wider than segment 2 or 3, none of segments ornamented by a special tuft of setae; pregula and adjacent surfaces flush with general contour of ventral surface of head; antennal club rather strongly flattened, without visible sutures, corneous area reduced, usually pubescent to base; lateral margins of pronotum acutely elevated, pleural area concave (on transverse axis); anterior margin of pronotum unarmed; protibia inflated, armed on its posterior face by minute tubercles; Africa, three species introduced into America; 1.4–4.7 mm *Premnobius*
- Basal segment of labial palpus enlarged, conspicuously wider than segment 2 or 3, its posterior face usually flat, 1 or more segments ornamented by an oblique row of setae; pregula and adjacent areas usually conspicuously impressed below general contour of head 2
- 2(1). Antennal club with sutures 1 and 2 rather strongly procurved, both segments 1 and 2 corneous and mostly glabrous except at sutures; protibia slender, almost cylindrical, posterior face armed by tubercles, lateral margins of pronotum acutely elevated, pleural areas transversely concave; body very slender; anterior margin of pronotum armed by 2 or more very coarse serrations; domicile parasites of other ambrosia beetles; Mexico to Brazil; 2.7–6.0 mm *Sampsonius*

- Antennal club obliquely truncate or nearly so, sutures (when visible) on or very near margin of corneous area, recurved (except pubescent to base in some Asiatic forms); protibia usually more strongly expanded on apical half; lateral margins of pronotum rounded; habit as domicile parasites unknown 3
- 3(2). Shallow sutural notch at base of elytra exposing depressed, cone-shaped scutellum that appears to be displaced cephalad, emargination usually filled by dense setae; femoral groove for reception of tibia visible only near apical joint; tropical and temperate areas worldwide; 1.4–3.5 mm *Xyleborinus*
- Scutellum visible, moderately large, its surface flush with adjacent surface of elytra; ventral margin of metafemur either rounded or rather obtusely angulate, on its posterior face groove for reception of tibia usually clearly indicated on distal half 4
- 4(3). Posterior face of antennal club marked by 2 sutures on apical third (suture 2 poorly represented in some *Coptoborus*), anterior face with apical portion convex (or concave only distad from segment 2), segment 2 comparatively large, sclerotized, protibia armed by 6 or 7 socketed teeth on lateral margin, metatibia with 6–9 socketed teeth; anterior coxae always contiguous 5
- Posterior face of antennal club with not more than 1 suture visible at or very near apex (usually none), apical portion of anterior face usually flat to concave, segment 2 (if visible) not corneous; number of metatibial teeth variable; anterior coxae either contiguous or separated 7
- 5(4). Protibia with posterior face inflated and armed by numerous small tubercles; metatibia usually with 8 or 9 socketed denticles; segment 2 of antennal club usually forming a complete oblique annulus on anterior face, its apical margin acutely costate as on segment 1; Mexico to South America (1 species introduced to Africa); 2.1–5.3 mm *Dryocoetoides*
- Protibia with posterior face flat, unarmed (except socketed denticles on lateral margin); metatibia never with more than 7 socketed teeth; apical margin of antennal club segment rounded, never acutely costate 6
- 6(5). Posterior fourth of elytra comparatively broad, rather broadly rounded behind, suture never emarginate; declivital interstriae 1–3 similar, tubercles minute, if present, body comparatively stout, less than 2.6 times as long as wide; Mexico to South America, also introduced into tropical Africa; 1.7–3.0 mm *Theoborus*
- Posterior third of elytra attenuate or acuminate, narrowly rounded behind, suture often emarginate; 1 or more declivital interstriae sometimes armed by small denticles, body slender, at least 2.6 times as long as wide; Mexico to South America, Africa to SE Asia; 1.5–5.0 mm *Coptoborus*
- 7(4). Antennal club with segment 2 on anterior face usually conspicuous, sometimes rather large, apical margin of segment 1 on both faces rounded, often inconspicuous or absent on anterior face, almost always visible on subapical area of posterior face; procoxae always contiguous, intercoxal piece never inflated or armed by spines, mesocoxae usually more widely separated by distance greater than thickness of antennal scape 8
- Segment 1 of antennal club corneous, its distal margin very acutely elevated into a continuous costa (forming a complete circle) extending from anterior face to apex, suture almost never visible on posterior face; procoxae varying from contiguous to widely separated, if contiguous then posterior intercoxal piece sometimes inflated and armed; mesocoxae usually subcontiguous, usually separated by distance less than thickness of antennal scape 10
- 8(7). Pronotal asperities extending to base, including most of discal area; anterior margin of pronotum never armed by a definite row of serrations; lateral margin of protibia armed by 7–8 socketed denticles, metatibia by 8–11 denticles; ventrolateral margin of declivity never costate; pantropical; 1.9–4.2 mm *Ambrosiodmus*

- Pronotal asperities confined to slightly more than anterior half; lateral margin of metatibia armed by 7 to more than 11 socketed denticles; ventrolateral margin of declivity weakly to acutely costate 9
- 9(8). Most of postolateral declivital margin rounded, a carina not indicated on its basal two-thirds, sub-acutely elevated from apex of suture to interstriae 7; declivital face basically convex; antennal club obliquely truncate in South American species; pronotum commonly subquadrate, its anterior margin almost always unarmed; striae and interstitial punctures usually in rows, elytral vestiture comparatively sparse, confined to striae and interstitial rows; Asia to Australia, introduced to South America; 2.4–4.6 mm *Euwallacea*
- Elytra obliquely, abruptly truncate behind, usually with an acutely, distinctly elevated circum-
declivital subcircular costa, face of declivity flat to concave (if costa absent then antennal club
pubescent to base); discal interstriae with punctures uniseriate, occasionally slightly confused on
some interstriae; antennal club usually pubescent to its base, more strongly flattened; eye deeply
emarginate to entirely divided; SE Asia to Australia, incorrectly reported from South America;
2.4–3.1 mm *Amasa*
- 10(7). Procoxae contiguous, intercoxal piece longitudinally emarginate, its posterior element inflated,
occasionally dentate; body usually more slender, mostly more than 2.0 times as long as wide; world-
wide in tropical and temperate areas; 1.7–5.9 mm *Xyleborus*
- Procoxae moderately to rather widely separated, intercoxal piece continuous, not longitudinally
emarginate (a slight notch in some *Taurodemus*); body usually stouter, mostly less than 1.9 times
as long as wide 11
- 11(10). Lateral margin of protibia armed by 9–12 socketed teeth; elytral declivity moderately to very
strongly sulcate on at least basal half, lateral margins armed by at least 1 major spine and several
smaller tubercles; procoxae moderately to rather narrowly separated; Central and South America;
2.4–4.5 mm *Taurodemus*
- Lateral margin of protibia armed by 4–7 socketed teeth; elytral declivity usually not conspicu-
ously sulcate, lateral margins not conspicuously armed by spines or tubercles; basal area of ely-
tral declivity convex; procoxae widely separated; pantropical; 1.3–5.0 mm *Xylosandrus*

GENUS *PREMNOBIUS* EICHHOFF

Premnobius Eichhoff, 1878:65, 404. Type-species: *Premnobius cavipennis* Eichhoff, monobasic (Synonymy and references in Wood & Bright c1992:651–655)

Premnophilus Browne, 1962:79. Type-species: *Xyleborus joveri* Schedl = *Premnobius quadrispinosus* Schedl, original designation

Diagnosis and description: Distinguished from other genera of the Xyleborini by the cylindrical segment 1 (basal) of the labial palpus that is only slightly wider than segment 2 or 3, none of these segments is ornamented by a special tuft of setae; by the pre-gula being flush with adjacent surfaces of the head (not conspicuously impressed); by the strongly flattened antennal club, without sutures, corneous area reduced, pubescent to base; by the acutely elevated lateral margins of the pronotum; by the unarmed anterior margin of the pronotum; and by the inflated protibia that is armed on its posterior face by minute tubercles.

Distribution: Wood & Bright (c1992:651–655) report 25 species from Africa, 3 of which have been introduced into South America.

Biology: The species are xylomycetophagous and reproduce by inbreeding or consanguineous polygyny, as described for the tribe. Adult females bore into unthrifty, fallen, or cut limbs larger than 3 cm in diameter and logs. The female bores about 3 cm directly (radially) into the wood. The tunnel may then branch or radiate palmately. Larvae develop in the parent tunnel and feed on the mycelial growth of the fungi cultivated by the beetles on their tunnel walls until just before pupation. Each forms its own pupation chamber immediately above or below the parent gallery. About 11–17 pupal cradles occur in each gallery system. Mating occurs in the brood chambers with the flightless males. Emergence is through the parent entrance hole.

Notes: This genus is intermediate between the Dryocoetini and Xyleborini. The (1) labial palpi, (2) non-impressed oral area on the ventral area of the head, and (3) DNA sequence data apparently suggest an affinity with Dryocoetini and Ipinini. However, the (1) xylomycetophagous habit with (2) larval/pupation cradles, and (3) the emergence of brood through the parent entrance

tunnel are clearly associated with the Xyleborini. This suggests an intermediate position between these 2 tribes that, at present, can be resolved only through author choice. More detailed studies of the habits and behavior of African species of this genus could be of great value in the proper placement of this genus.

Key to the Species of *Premnobius*
(Modified from Wood 1982:756)

- 1. Punctures of discal striae and interstriae in definite rows; declivity strongly concave, lateral margins armed by 4 major and about 4 minor spines; body smaller, more slender, 3.9 times as long as wide; tropical Africa (?) and Suriname; 2.1–3.0 mm ***sexnotatus*** (Schedl)
- Interstitial punctures on elytral disc confused (minute strial punctures sometimes in rows); elytral declivity rather strongly concave, lateral margins armed by 1 large denticle or none (2–3 very small denticles sometimes present); body larger, less slender; 3.0–3.3 times as long as wide 2
- 2(1). Smaller; declivital interstriae 1 with a row of small, pointed tubercles; declivity steeper, occupying only 33 percent of elytra length, its lateral margin finely serrate, a slightly larger tubercle near middle, another on lower fourth; Africa, Florida (USA) to Brazil; 2.3–2.8 mm ***cavipennis*** Eichhoff
- Larger; declivital interstriae 1 entirely unarmed; declivity occupying 43 percent of elytra length, its lateral margins each armed by about four rather coarse tubercles on upper third and one much larger, blunt spine slightly below middle; tropical Africa, and Colombia and Venezuela to Bolivia and Brazil; 3.0–3.3 mm ***ambitosus*** (Schauffuss)

Premnobius sexnotatus (Schedl)
Plate LXXVIII

Premnobius sexnotatus (Schedl), 1970:95 (*Xyleborus*). Holotype ♀; Para Distr.; Suriname; NHMW, Wien (References in Wood & Bright c1992:655)

Diagnosis: Distinguished by the small, slender body form; by the deeply excavated elytral declivity and the coarse lateral spines; and by the clearly uniseriate punctures of the discal striae and interstriae.

Female: Length 2.1–3.0 mm, 2.9 times as long as wide; color yellowish brown. Frons convex, reticulate, obscurely punctured; vestiture of short, sparse hair. Pronotum 1.4 times as long as wide; summit one-third pronotum length from anterior margin, anterior slope steep, armed by numerous, small, confused asperities; disc smooth, obscurely reticulate, punctures sparse, minute; vestiture absent except a few sparse, short setae on anterior and lateral areas. Elytra 2.2 times as long as wide, 1.5 times as long as pronotum; striae not impressed, punctures rather small, shallow, in rows; interstriae three times as wide as striae, smooth, shining, punctures minute, half as large as those of striae, in uniseriate rows. Declivity occupying posterior third of elytra length, rather deeply concave; lateral margins armed by 3 pairs of coarse spines on less than lower half, by 2 or more pairs of smaller spines on basal half; face of declivity reticulate, punctures not clearly indicated. Vestiture on disc of rather short, sparse interstitial setae, longer and more numerous on margins of declivity.

Distribution: Suriname to Brazil.

Brazil: Cited in Wood & Bright (c1992:655).

Suriname: Jodensavane, Kamp 8, 1961, Lichtv., #765, Schulz.

Notes: The above treatment was based on 1 female from a Suriname light trap. It was compared by me to the slightly larger female holotype (3.0 mm), also from Suriname. It is an obvious introduction from Africa of a species near *hystrix* (Schedl).

Premnobius cavipennis Eichhoff
Plate LXXVII

Premnobius cavipennis Eichhoff, 1878:404. Syntypes ♀; Africa meridionalis (Cap bonae spei), America meridionalis (Colombia); most lost with Hamburg Museum, 1 in IRSNB, Brussels (Synonymy and references in Wood & Bright c1992:651–652)

Xyleborus industrius Sampson, 1912:248. Holotype ♀; Uganda; BMNH, London

Xyleborus xylocranellus Schedl, 1931:344. Holotype ♀; Brazil; NHMW, Wien

Premnobius bituberculatus Eggers, 1932:35. Holotype ♀; Congostaat, Region de Sassa; MRCB, Tervuren

Premnobius latior Eggers, 1933:9. Holotype ♀; St. Jean du Maroni, French Guyane; MNHN, Paris

Diagnosis: Distinguished by characters presented in the above key to species.

Male: Described and figured by Browne (1961:46) and Wood (1982:756–758). Similar to female but smaller and less perfectly formed.

Female: Length 2.3–2.8 mm, 3.3 times as long as wide; color reddish brown. Frons broadly convex, median line

usually feebly elevated; surface subreticulate, obscurely punctured above, some punctures replaced by fine granules below. Pronotum 1.2 times as long as wide; outline as in *sexnotatus* (Schedl); posterior areas smooth, shining, very finely, rather deeply, closely punctured; lateral margins subacute; vestiture of fine, short, rather abundant hair. Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; striae not impressed, punctures minute, usually not in recognizable rows; interstriae smooth, usually with minute, impressed points, punctures small, confused, mostly indistinguishable from those of striae. Declivity broadly, rather deeply, concavely excavated on posterior third of elytra length; lateral margins distinctly higher than suture; interstriae 1 with a row of fine, pointed tubercles; declivital face with rather large, moderately deep, confused punctures, shining; lateral margins on upper half with a row of minute denticles, a slightly larger denticle near middle; lower half with one to three minute denticles, a moderately large denticle on margin on lower fourth; ventrolateral margin obsolete before apex. Vestiture of abundant, rather short, fine hair, somewhat longer and coarser at base of declivity.

Distribution: Africa, introduced to America in USA (Florida), Mexico (Chiapas, Veracruz, Yucatan), Honduras, Cuba, Guadeloupe, Puerto Rico, Trinidad, and South America south to Brazil.

Brazil: Cepec, Ilheus, Bahia, 1966–1968, at light, Kaston; “Brazil, J.L. Saunders”; Aracruz, Espirito Santo, 11-XII-1991, No. 3565; Rio Grande do Sul, Sao Francisco de Paula, I-1992, ethanol trap in *Pinus taeda* stand, A. Dwulatka; Sao Paulo, Duraflora, Agudos, 17-IV-1984, ethanol trap in *Pinus caribaea* stand, C.A.H. Flechtman.

Colombia: Colombia (Eichhoff 1878:404); El Silencio, Nito Palermo, Hulla, 27-IV-1959, Cacao arbol, B. Herrera.

French Guyane: Cited in Wood & Bright (c1992:652).

Guiana: Cited in Wood & Bright (c1992:652).

Suriname: Cited in Wood & Bright (c1992:652).

Venezuela: 9 km S Barrancas, Barinas, 5-XI-1969, 60 m, No. 116, *Inga*, SLW; 8 km SW Bumbum, Barinas, 11-II-1970, 150 m, No. 309, tree limb, SLW; Merida, Merida, 22-IX-1969, 1700 m, SLW; 17 km SE Miri, Barinas, 17-XII-1969, 150 m, No. 199, *Bombacopsis quinata*, SLW; 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 262, *Protium*, SLW; Finca Monasterios, Cacaagua, Miri, 1971, *Theobroma cacao*.

Hosts: African hosts (59 plant genera) cited in Wood & Bright (c1992:652). South American hosts include *Bombacopsis quinata*, *Inga*, *Protium*, and *Theobroma cacao*.

Biology: As described for the genus.

Notes: The above treatment was based on 4 specimens from Zaire (Africa), on 21 from North America and the Antilles Islands, on 6 from Brazil, 3 from Colombia, 29 from Venezuela, and 1 or more each from French Guyane, Guiana, and Suriname.

Premnobius ambitiosus (Schaufuss)

Plate LXXVII

Premnobius ambitiosus (Schaufuss), 1897:109 (*Xylocleptes*). Holotype ♀; Gabun; Hamburg Museum, lost (Synonymy and references in Wood & Bright c1992:651)

Premnobius cavipennis spinosus Hagedorn, 1908:376. Syntypes ♀; Kinshasa, Waelbroek, Congo; IRSNB, Brussels

Premnobius brasiliensis Nunberg, 1958:490. Holotype ♀; Sao Paulo, Brazil; Escola Nacional de Agronomia, Rio de Janeiro (Now at MZUSP, Sao Paulo)

Diagnosis: Distinguished from *cavipennis* Eichhoff by the larger size; by the unarmed declivital interstriae 1; and by having a rather large spine just below the middle of the lateral margin of the declivity.

Female: Length 3.0–3.3 mm, 3.0 times as long as wide; color reddish brown. Frons convex, weakly reticulate, a feeble median elevation obscurely indicated; small punctures moderately abundant, some of them accompanied by a small granule. Pronotum 1.3 times as long as wide; summit distinctly in front of middle; anterior slope closely, moderately asperate; posterior areas smooth, shining, punctures small, rather close; vestiture of fine, rather short hair on anterior and lateral areas. Elytra 1.7 times as long as wide, 1.3 times as long as pronotum; striae not impressed, rather obscurely indicated by rows of small, shallow punctures; interstriae smooth, shining, five or more times as wide as striae, punctures confused, each slightly smaller than those of striae. Declivity occupying about 43 percent of elytral length, broadly, rather strongly concave; lateral margins subacutely elevated much higher than suture, a rather large, conical spine moderately displaced mesad from margin at level about two-thirds distance from base of declivity toward apex, about 5–7 smaller denticles on margin on basal half, crest below major spine subacute, a small denticle at mesal end in line with position of striae 1; face of declivity mostly smooth, shining, some reticulation in lateral areas, large, shallow, confused punctures moderately abundant. Vestiture of fine, moderately long hair, sparse on disc and declivity, moderately abundant on sides and near base of declivity.

Distribution: Tropical Africa, introduced to South America (Colombia and Venezuela to Bolivia and Brazil).

Bolivia: Cited in Wood & Bright (c1992:651).

Brazil: Rio de Janeiro; Ibateripasa, Sao Paulo, 27-III-1985, 8-IV-1985, 10-IV-1985, ethanol trap in *Eucalyptus* stand, C.D. Santos.

Colombia: Dinamarca, La Coqueta Seville, Valle de Cauca, V-1959, en guamo, A. Duque V.

Venezuela: Finca Monasterios, Cacaagua, Miranda, *Theobroma cacao*, J.L. Saunders.

Hosts: *Albizzia* spp., *Celtis mildbraedii*, *C. soyaurii*, *Gmelina arborea*, *Gossypium hirsutum* (fruit), *Mangifera indica*.

Biology: Apparently as described for the genus (not studied by me).

Notes: The above treatment was based on 4 specimens from Africa, 1 from Colombia, and 1 from Venezuela.

The identification was based on direct comparisons of my specimens to those of Browne (BMNH, London) and Schedl (NHMW, Wien).

GENUS *SAMPSONIUS* EGGERS

Sampsonius Eggers, 1935:157. Type-species: *Sampsonius sexdentatus* Eggers, original designation (References in Wood & Bright c1992:655–656)

Diagnosis: Distinguished from other genera of Xyleborini by having the antennal club with sutures 1 and 2 rather strongly procurved, setments 1 and 2 on anterior face corneous and mostly glabrous; protibia slender, its posterior face armed by tubercles; lateral margins of pronotum acutely elevated; anterior margin of pronotum armed (usually) by 2 very coarse serrations that may play a significant role in their habit as domicile parasites of other ambrosia beetles.

Description: Female body very slender, 3.9–4.1 times as long as wide; color yellowish to reddish brown. Male dwarfed, deformed, flightless. Antennal club flattened, sutures 1 and 2 moderately procurved, segments 1 and 2 corneous on anterior face. Pronotum elongate, summit well in front of middle, anterior slope asperate, anterior margin armed by 2 coarse serrations (absent in 3 species); lateral margins subacutely elevated. Elytra elongate, weakly striate; declivity gradual, variously, often remarkably sculptured. Procoxae contiguous, intercoxal

piece obsolete. Protibia slender, posterior face armed. Male dwarfed, anterior slope of pronotum impressed to excavated; elytral declivity less strongly impressed, less perfectly formed than in female.

Distribution: Wood & Bright (c1992:655–656) report 3 species from Central America and 12 species from South America. See Bright (1991:11–28), revision.

Biology: All are xylomycetophagous domicile parasites of other ambrosia beetles, usually (always?) a species of another genus of Xyleborini. The critical factor in host-beetle selections appears to be the diameter of the entrance hole of the host-beetle tunnel. After the host-beetle species is established its tunnel in small-diameter stems (about 3–8 cm in diameter) of shrubs or tree seedlings, the *Sampsonius* species arrives, forces entry (apparently using the large prothoracic spines), and evicts the original tenant, eggs, larvae, and boring dust. It then produces its own brood in that appropriated tunnel. The beetles are solitary and are usually found through accidental encounters. There appears to be no aggregation factor present unless the host species produces something that attracts the domicile parasite.

Note: Schoenherr (1994:63–69) named *S. Giganteus*, *S. Prolongus*, and *S. Pedrosai* from Brazil. Requests for a loan of these species and for publication data not answered by the author and could not be included here. Synonymy is suspected.

Key to the Species of *Sampsonius*
(Females only)

- 1. Anterior margin of pronotum procurved, unarmed by serrations 2
- Anterior margin of pronotum variously produced in median area, armed by 2 large serrations . . . 4
- 2(1). Median area of pronotum without a serrated crest immediately behind anterior margin; elytral declivity impressed, armed on interstriae 3 by two rather short, subacutely pointed spines; Brazil (Mato Grosso); 4.3 mm *alvarengai* **Bright**
- Median area of pronotum immediately behind anterior margin armed by a serrated crest; elytral declivity impressed, armed on interstriae 3 by three large spines (either blunt or elongate) 3
- 3(2). Declivity moderately impressed, interstriae 3 armed by three shining, acutely pointed spines, 1 shorter, 2 and 3 longer; French Guyane; 7.9 mm *sexdentatus* **Eggers**
- Declivity rather strongly impressed, interstriae 3 armed by three dull, reticulate, obtusely pointed, short spines of about equal length; Guiana; 5.4 mm *coniferae* (**Hagedorn**)
- 4(1). Elytral declivity variously, broadly impressed (never concave), surfaces partly to entirely reticulate, lateral margin moderately, subacutely elevated and armed by a row of numerous small denticles 5
- Elytral declivity rather strongly concave, lateral margins strongly, acutely elevated, crest armed by about 3 small spines 13
- 5(4). Elytral declivity not armed by major spines on lower half 6
- Elytral declivity armed by 1 or more pair of conspicuous spines on lower half 8

- 6(5). Declivity dull, reticulate except interstriae 1 or 2 (?) with a shining, longitudinal elevation (half as long as length of declivity) beginning near apex of 1 and continuing to an obtuse elevation above; Brazil (Sao Paulo); 4.6–4.8 mm *pennatus* Schedl
 — Declivity dull, reticulate, without any conspicuous elevations 7
- 7(6). Declivity moderately impressed, a moderate, longitudinal sulcus on median half from base almost to apex, lateral areas (presumably interstriae 3) moderately elevated (summit obtusely rounded); Mexico (Veracruz); 5.4–6.0 mm *reticulatus* Bright
 — Declivity strongly impressed, transversely almost flat, suture and lower third of interstriae 3 weakly elevated; Colombia (Valle de Cauca); 5.1 mm *expulsus* Wood
- 8(5). Elytral declivity armed by 2 pair of spines (on interstriae 3?); Bolivia; 5.4 mm
 *quadrispinosus* Eggers
 Elytral declivity armed by 1 pair of spines on lower fourth 9
- 9(8). Declivity armed by 1 pair of subcontiguous, modified spines near apex of interstriae 1 10
 — Declivity armed by 1 pair of widely separated spines on lower fourth of interstriae 3 12
- 10(9). Elytral declivity modestly sulcate, interstriae 3 moderately, obtusely elevated on lower two-thirds of elytral length; interstriae 1 armed by a small, acutely pointed spine on suture at apex; declivital vestiture longer and more abundant; Costa Rica; 4.0–4.4 mm *usurpatus* Wood
 — Elytral declivity not sulcate, interstriae 3 not elevated to very weakly elevated; elevated spine-like process at apex of interstriae 1 much larger 11
- 11(10). Declivital spines near apex of elytral suture contiguous, their mesal side often contiguous to apex of spines, basal longitudinal axis of spine often prolonged on its anterior face; Mexico (Chiapas) to Panama and Venezuela to Brazil; 2.8–4.7 mm *dampfi* Schedl
 — Declivital spines near apex of suture contiguous at their base, strongly diverging to their apices, spines usually longer, their basal axis shorter; Brazil (Bahia to Santa Catarina); 4.8 mm
 *buculus* Schedl
- 12(9). Declivital spine near apex of interstriae 3 very slender, about four times as long as its basal (longitudinal) width, almost straight, slightly curved at apex, lateral base of spine not attaining lateral margin; Panama (Canal Zone); 5.8–6.0 mm *detractus* Wood
 — Declivital spine near apex of interstriae 3 long, stout, about twice as long as longitudinal basal width, distinctly curved on its apical half, lateral base attaining lateral margin; French Guyane to Brazil (Mato Grosso); 5.5–6.2 mm *ensifer* Wood
- 13(4). Elytral declivity moderately steep, lateral margins strongly rounded; declivital face rugose-reticulate, apical profile (dorsal aspect) rounded; Trinidad; 3.8 mm *sulcatus* Bright
 — Elytral declivity more gradual, concavely excavated, conspicuously emarginate at sutural apex, lateral margin strongly, acutely elevated, its summit armed by 3 or more pointed denticles; face of declivity smooth, shining between punctures; Costa Rica and Brazil (Parana, Sao Paulo) to Peru; 3.0–3.5 mm *obtusicornis* Schedl

Sampsonius alvarengai Bright

Sampsonius alvarengai Bright, 1991:15. Holotype ♀; Vera, Mato Grosso, Brazil; CNCI, Ottawa (References in Wood & Bright c1992:655)

Diagnosis: Distinguished by the evenly procurved, unarmed anterior margin of the pronotum and absence of a submarginal costa; by the somewhat concave elytral declivity the lateral margins of which are armed by 2 pair of coarse denticles (on interstriae 3?).

Female: Length 4.3 mm, 3.1 times as long as wide. Head and pronotum about as in allied species, except anterior margin of pronotum procurved and unarmed by serrations, submarginal costa absent. Elytra 2.0 times as long as wide, rather broadly rounded behind; striae punctures large, deeply impressed; interstriae almost as wide as striae, smooth, shining, punctures small, uniseriate. Declivity occupying posterior half of elytral length, reticulate, moderately concave on interstriae 1 and 2,

suture distinctly elevated, strial punctures not indicated; lateral margins armed by 2 pair of moderately coarse spines (apparently on interstriae 3) of subequal size; lateral areas rounded.

Distribution: Brazil: Mato Grosso, Vera, X-1973, M. Alvarenga.

Notes: The above treatment was modified from Bright (1991:15–16).

Sampsonius sexdentatus Eggers

Sampsonius sexdentatus Eggers, 1933:23. Holotype ♀; Gourdonville, French Guyane; MNHN, Paris (References in Wood & Bright c1992:656)

Diagnosis: Distinguished from *alvarengai* Bright by having a submarginal, serrated costa behind the unarmed anterior margin of the pronotum; by the smaller strial punctures; by the weakly concave declivity, with the lateral margins armed by three pair of moderately coarse denticles (on interstriae 3).

Female: Length 7.9 mm, 3.4 times as long as wide. Head and pronotum about as in *alvarengai*, except a submarginal serrated costa present behind unarmed anterior margin of pronotum. Elytra 2.0 times as long as wide, rather broadly rounded behind; strial punctures rather small, weakly impressed; interstriae two to three times as wide as striae, smooth, shining, punctures small, uniseriate. Declivity occupying posterior half, reticulate, broadly, shallowly concave, strial punctures obsolete, armed on lateral margin by three pair of spines, spines increasing in size from moderate to rather large from 1 to 3 (apparently on interstriae 3); lateral areas rounded.

Distribution: French Guyane: Gourdonville, 1907, E. Le Moutl.

Notes: The above treatment was modified from Bright (1991:18).

Sampsonius conifer (Hagedorn)

Sampsonius conifer (Hagedorn), 1905:540 (*Xyleborus*). Holotype ♀; Riviere Lunier, French Guyane; MNHN, Paris (References in Wood & Bright c1992:655)

Diagnosis: Distinguished from *sexdentatus* (Eggers) by the smaller size; by the shorter, equal size of the peg-like (acorn-shaped) declivital spines; by the weakly serrated costa immediately behind the anterior margin of the pronotum.

Female: Length 5.0 mm, 3.3 times as long as wide (Bright 1991:16 gives 5.4 mm, 3.6 times as long as wide); color reddish brown. Frons as in *detractus* Wood. Pronotum 1.5 times as long as wide; as in *detractus* except anterior slope devoid of asperities, anterior margin unarmed except for a low submarginal costa on median fourth. Elytra 2.0 times as long as wide, 1.3 times as long as pronotum; disc occupying basal half; strial punctures large for this genus, distinctly impressed, close; interstriae slightly wider than striae, smooth,

shining, punctures small, uniseriate. Declivity strongly concave, lateral margins rounded, not serrate; concave area rugose-reticulate, punctures not evident, armed on interstriae 3 by three pair of large, black, reticulate, stout spines (resembling pointed acorns of *Quercus*, complete with caps at their base), of almost equal size, each spine about 1.5 times as long as its basal width and slightly inclined mesad.

Distribution: French Guyane: Riviere Lunier, 1899, F. Geay.

Notes: The above treatment was based on my examination of the female holotype and the notes recorded on 5 June 1972.

Sampsonius pennatus Schedl

Plate LXXX

Sampsonius pennatus Schedl, 1973:171. Holotype ♀; Guanabara, Repressa Rio Grande, Brazil; MZUSP, Sao Paulo (References in Wood & Bright c1992:656)

Diagnosis: Distinguished by the unique elevation on declivital interstriae 1 as described below.

Female: Length 4.6–4.8 mm, 3.8 times as long as wide. Frons and pronotum about as in *detractus* Wood except frons with a weak median elevation, pronotum 1.45 times as long as wide. Elytra 1.4 times as long as wide, broadly rounded behind; strial punctures rather large, impressed; interstriae as wide as striae, punctures small, uniseriate. Declivity confined to posterior third of elytral length, reticulate; interstriae 3 slightly elevated, with numerous fine granules on crest of summit, 1 weakly elevated and with a few granules, 2 weakly impressed and with a few granules, interstriae 7 forming lateral margin below, sharply elevated, moderately serrate, largest serrations ending at 5; “apex of interstriae 1 bearing a distinct, strongly elevated process which extends half of declivital length, lateral margin of process acutely elevated, ending in an acute elevation on anterior end of process, surface of process smooth, glabrous, brightly shining” (Bright 1991:20).

Distribution: Brazil: Sao Paulo, Guanabara, Repressas Rio Grande (apparently a vacation resort near Rio de Janeiro), XII-1967, F.M. Oliviera; INPA Campus, Manaus, Amazonas, 23-II-1987, ethanol trap, R.L.S. Abreu.

Notes: The above treatment was adapted from Bright (1991:20). Two specimens from Brazil were examined.

Sampsonius expulsus Wood

Plate LXXIX

Sampsonius expulsus Wood, 1974:31. Holotype ♀; Carton de Colombia forest 8 km S Colonia (near Buenaventura), Valle de Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:656)

Diagnosis: Distinguished from *reticulatus* Bright by the more strongly impressed, transversely almost flat elytral declivity, the lower third of interstriae 3 weakly elevated.

Female: Length 5.1 mm, 3.4 times as long as wide; color reddish brown. Frons convex, reticulate, narrow, not as wide as width of an eye; area on and near epistomal margin finely, closely tuberculate; vestiture sparse, fine, long, hairlike. Pronotum 1.5 times as long as wide; anterior margin narrowly rounded, armed by 2 large, slender, basally subcontiguous, median serrations; summit indefinite, near middle; crenulations on anterior slope low, small, except in median area near anterior margin; disc smooth, brightly shining, punctures sparse, minute. Elytra 2.2 times as long as wide, 1.6 times as long as pronotum; disc occupying slightly more than half of elytra length, striae not impressed, punctures small, impressed, in definite rows, interstriae almost flat, smooth, shining, punctures very small, uniseriate near base, confused near declivity. Declivity gradual, abruptly subtruncate, broadly impressed, transversely straight, longitudinally concave, rugose-reticulate; interstriae 1 and 3 weakly elevated on lower half; striae punctures minute, uniseriate, interstitial punctures minute, some finely granulate, uniseriate; interstitial vestiture of fine, long, moderately abundant hair on sides and declivity.

Distribution: Colombia: Carton de Colombia forest 8 km S Colonia, Valle de Cauca (near Buenaventura), 7-VII-1970, 30 m, *Pouteria*, SLW.

Biology: Domicile parasite in a *Xyleborus* sp. gallery in a branch of a recently felled tree.

Notes: The above treatment was based on the female holotype.

Sampsonius quadrispinosus Eggers

Sampsonius quadrispinosus Eggers, 1935:158. Holotype ♀; Cochabamba, Bolivia; NHMW, Wien (References in Wood & Bright c1992:656)

Diagnosis: This is the only known species of this genus having both 2 serrations on the anterior margin of the pronotum and also 2 pair of major spines on the elytral declivity.

Female: Length 5.4 mm, 3.9 times as long as wide. Frons and pronotum about as in *usurpatus* Wood, pronotum 1.5 times as long as wide, anterior margin armed by 2 coarse serrations. Elytra 2.3 times as long as wide, very broadly rounded (almost straight) behind; striae punctures on disc moderately large, shallowly impressed; interstriae twice as wide as striae, smooth, shining, punctures very small, uniseriate. Declivity occupying posterior third of elytral length, surface reticulate near major spines, with numerous small, scattered, acute granules, lower half armed by 2 pair of large, acute spines, area between spines smooth, shining; interstriae 7 below forming ventrolateral margin, rather coarsely serrate, row of serrations continuing cephalad to suture (forming most of a circumdeclivital ring of small spines); major spines apparently on interstriae 3 (not stated).

Distribution: Bolivia to Brazil (Mato Grosso).

Bolivia: Cochabamba [F. Woytkowski]

Brazil: Sao Nicolau Farm, Catriguacu, Mato Grosso, VI-2002, Amazon rain forest, ethanol trap, P. Filho.

Notes: The above treatment was modified from Bright (1991:21, fig. 11), and 1 female.

Sampsonius usurpatus Wood

Sampsonius usurpatus Wood, 1974:32. Holotype ♀; Turrialba, Cartago, Costa Rica; USNM, Washington (References in Wood & Bright c1992:656)

Diagnosis: Distinguished from *dampfi* Schedl by the moderate declivital sulcus from suture to moderately elevated interstriae 3 on lower two-thirds of declivital length; by the smaller spine at apex of declivital interstriae 1; and by the longer, more abundant declivital vestiture.

Male: Length 3.3 mm; pronotum almost as long as elytra, anterior half strongly, concavely excavated, anterior margin armed by 3, stout spines; declivity remotely resembling female, declivity narrower, almost convex, spine absent at end of suture.

Female: Descriptions in Wood (1974:32, 1982:761).

Distribution: Costa Rica to Panama.

Hosts: Unidentified recently cut tree seedlings and tree branches.

Biology: Specimens were removed from partly to completely formed tunnels of *Dryocoetoides capucinus* (Eichhoff); *dampfi* is a domicile parasite of this species.

Notes: Although not yet recorded from South America, its occurrence in Costa Rica and Panama and the occurrence of the host beetle in South America suggest that it will eventually be found there.

Sampsonius dampfi Schedl

Plate LXXIX

Sampsonius dampfi Schedl, 1940:359. Lectotype ♀; Chiapas, Mexico; NHMW, Wien, designated by Schedl 1979:75 (Synonymy and references in Wood & Bright c1992:655)

Sampsonius costaricensis Nunberg, 1963:104. Lectotype ♀; Finca La Lola, Limon, Costa Rica; University of Wisconsin Collection, Madison, designated by Wood (1982:761)

Diagnosis: Distinguished from *usurpatus* Wood by the spines near apex of elytral suture larger, their basal longitudinal axis much longer than their transverse axis; by the elytral declivity being weakly if at all sulcate, with interstriae 3 feebly elevated.

Female: Length 2.8–4.2 mm, 4.1 times as long as wide; color yellowish brown to reddish brown. Frons and pronotum about as in *usurpatus*. Elytra resembling *usurpatus* except basal margin of declivity more gradually rounded, lateral margin of declivity more coarsely serrate, spine at apex of suture much larger, blunt, longitudinal axis of its base occupying up to lower third of declivital length; declivital vestiture less abundant.

Distribution: Mexico (Chiapas) to Panama and Venezuela to Brazil.

Brazil: "Brazil, J.L. Saunders"; Reserva Ouecc, Armadilha, 3-V-1993, A.P. Santos; Adelphoduke Forest Reserve,

Manaus, Amazonas, 1-III-1993, ethanol trap, W5, FA. Campos; Aracruz, Bahia, 25-VI-1997, Celulose SA, Nova Vicosa, ethanol trap, *Eucalyptus grandis* stand, C.A.H. Flechtmann; Champion Papel e Celulose, Horto Rio Verde, Tres Logoas, MS, ethanol trap, *Eucalyptus grandis* stump, C.A.H. Flechtmann; Mato Grosso, Itiquira, 28-II-1993, *Hevea brasiliensis*, GTI stand, ethanol trap, O.T. Dall'Oglio; Telemaco Borba, Parana, Klabin Papel e Celulosa, ethanol trap in *Pinus taeda* stand, C.A.H. Flechtmann; Sao Paulo, Agudas Duraflora, 9-IV-1985, *Pinus caraibica hondurensis* stand (trap?), C.A.H. Flechtmann; Sao Paulo, Ibate Ripasa, 13-III-1985, *Eucalyptus* stand, C.D. Santos.

Colombia: 24 km E Barbosa, Antioquia, 18-VII-1970, 1200 m, No. 697, *Inga*, SLW.

Venezuela: 30 km N Canyon Zancudo, Merida, 4-VI-1970, 10 m, No. 515, tree seedling, SLW; Barrancas, Barinas, 5-VI-1969, 150 m, No. 257, *Protium*, SLW; Barrancas, Barinas, 5-XI-1969, 150 m, *Spondias mombin*, SLW; Canton, Barinas, 8-III-1970, 70 m, No. 348, tree seedling, SLW; 7 km NW Socopo, Barinas, 13-II-1970, 200 m, No. 324, *Protium*, SLW; 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 257, *Protium*, SLW; Campamento Rio Grande 30 km E Palmar, Bolivar, 13-VI-1970, 1200 m, *Trichilia propingua*, SLW.

Hosts: *Inga* sp., *Protium* sp., *Spondias mombin*, *Trichilia propingua*.

Biology: This was a domicile parasite of *Dryocoe-toides capucinus* in cut or broken stems about 2 to 5 cm in diameter.

Notes: The above treatment was based on 9 specimens from Mexico and Central America, 1 from Brazil, 2 from Colombia, and 9 from Venezuela. One female in my series was compared by me directly to the lectotypes of *dampfi* Schedl and *costaricensis* Nunberg.

Sampsonius buculus Schedl

Plate LXXVIII

Sampsonius buculus Schedl, 1937:170. Holotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien (References in Wood & Bright c1992:655)

Diagnosis: Distinguished from *dampfi* Schedl by the contiguous spines at apex of declivital suture strongly diverging laterad from their base toward their apices, their longitudinal basal axis much shorter.

Female: Length 4.3–4.8 mm, 4.1 times as long as wide; color reddish brown. Head and pronotum as in *dampfi*. Elytra as in *dampfi* except interstitial punctures on disc closer, more distinctly impressed; base of declivity more abrupt; spines at apex of declivital suture more slender, much longer, their longitudinal axis at base reduced to about half, spines basally contiguous, diverging strongly laterad toward their apices.

Distribution: Brazil: Cepec Ilheus, Bahia, 1966–1968, at light; Nova Vicosa, Bahia, 25-VI-1997, *Eucalyptus grandis* stand, ethanol trap, C.A.H. Flechtmann; Sao Paulo, Jarinu, 23-IV-1991, *Eucalyptus saligna* stand, ethanol trap, SAM D, A.D.W. Vlatka.

Notes: One female from Brazil (Bahia) was compared to the female holotype by me. Six specimens from Brazil were examined.

Sampsonius detractus Wood

Sampsonius detractus Wood, 1974:31. Holotype ♀; Madden Forest, Canal Zone, Panama; USNM, Washington (References in Wood & Bright c1992:655)

Diagnosis: This species and *ensifer* Wood are distinguished from all other known members of this genus by the presence of a pair of widely separated, long spines on the lower half of the elytral declivity; this species is distinguished from *ensifer* by the more abrupt basal margin of the elytral declivity, and by the much more slender spines on the lower declivity, the longitudinal and transverse thicknesses are about equal.

Female: Length 5.8–6.0 mm, 4.0 times as long as wide; color reddish brown. Frons and pronotum essentially as in *expulsus*, punctures on pronotum disc distinctly smaller than in *ensifer*. Elytra 2.3 times as long as wide, 1.5 times as long as pronotum; disc occupying slightly more than basal half, striae not impressed, punctures small, uniseriate; interstriae about three times as wide as striae, smooth, shining, punctures very small, uniseriate. Basal and lateral margins of declivity rather abrupt, subserrate at base, moderately serrate laterally below; declivital face rugose-reticulate, more strongly, broadly impressed than in *ensifer*; interstriae 3 weakly convex on lower half, spine near apex of 3 very slender, about 4.0 times as long as its basal width, longitudinal and transverse widths at base about equal, apex more narrowly, sharply pointed; posterolateral base of spine separated from serrate lateral margin of declivity by basal thickness of spine. Declivital vestiture rather coarse, long, abundant.

Distribution: Panama: Canal Zone, Barro Colorado Island, 10-16-X-1984, at light, H. Wolda; Madden Forest Canal Zone, 2-I-1964, 70 m, tree limb, SLW.

Notes: Not represented from South America, but probably present in Colombia and Venezuela.

Sampsonius ensifer Wood, n.sp.

Sampsonius ensifer Wood. Holotype ♀; Petit-Saut, French Guyane, 24-31-X-1989, Foret primaire, Plege Malaise, H.P. Aberlenc; USNM, Washington, designated below

Diagnosis: Distinguished from *detractus* Wood by the less abrupt basal margin of the elytral declivity, with the basal area more nearly convex, less strongly impressed, and by the much thicker spines on the lower declivity, longitudinal thickness at base at least twice transverse thickness.

Female: Length 5.5 (type) 6.2 mm, 4.0 times as long as wide; color reddish brown. Frons and pronotum essentially as in *detractus*, punctures on pronotum disc slightly larger. Elytral disc about as in *detractus*, base of declivity rounded (not abrupt), upper declivity more

nearly convex, not as strongly impressed below; resembling *detractus* except on lower half crest of interstriae 3 more strongly elevated to base of spine near apex, longitudinal thickness of spine at base at least twice as great as transverse thickness, apex much more blunt; spine about 2.2 times as long as longitudinal thickness at base, posterolateral base of spine touching subserrate lateral margin of declivity.

Distribution: French Guyane to Brazil.

Type material: The female holotype was taken at Petit-Saut, French Guyane, 24-31-X-1989, Forêt primaire, Plege Malaise, H.P. Aberlenc; it is in the U.S. National Museum. Three paratypes are from Manaus, Amazonas, Brazil, 15-VII-1993, Adolpho Ducke Forest Reserve, ethanol trap, A.P. Santos (1 specimen); Mato Grosso, Itiquira, 15-IV-1993, *Hevea brasiliensis* clone, Rimagoo stand, ethanol trap, O. Dall'oglio (2 specimens); 2 paratypes are from Panflorq Farm, Jangaa, Mato Grosso do Sul, Brazil, X-2000, ethanol trap in *Tectona grandis* stand, P. Filho. Two of these paratypes are in the collection of MZUSP, Sao Paulo, Brazil; 1 paratype is in the USNM, Washington.

Sampsonius sulcatus Bright

Sampsonius sulcatus Bright, 1981:163. Holotype ♀; Trinidad; CNC, Ottawa (References in Wood & Bright c1992:656)

Diagnosis: Distinguished from *obtusicornis* Schedl by the stouter body form; by the concave elytral declivity, with major denticles on the lateral margin of the basal half; and by the absence of an emargination at the apex of the suture.

Female: Length 3.6–3.8 mm, 3.6 times as long as wide. Head and pronotum similar to *obtusicornis*. Elytra 2.1 times as long as wide; striae punctures large, deeply impressed; interstriae about as wide as striae, punctures small, uniseriate. Declivity moderately steep, deeply impressed, sutural apex broadly rounded, not emarginate; lateral margins (apparently interstriae 3) rather strongly elevated, higher than 1, basal half of margin armed by 3 or 4 acutely pointed major denticles, minor granules on basal half; concave area reticulate, with several small granules. Vestiture of long hair, rather abundant on declivity.

Distribution: Trinidad: Morne Bleu, 6-VIII-1969, 2700 feet, H. & A. Howden.

Notes: The above treatment was based on Bright (1991:26–27, fig. 17).

Sampsonius obtusicornis Schedl

Plate LXXX

Sampsonius obtusicornis Schedl, 1976:78. Holotype ♀; Filtro, Brazil; NHMW, Wien (References in Wood & Bright c1992:656)

Diagnosis: Distinguished from *sulcatus* Bright by the more gradual, concavely excavated elytral declivity, with the sutural apex emarginate; and by the denticles that arm the lateral margin of the declivity extend to lower half.

Female: Length 3.0–3.5 mm, 4.0 times as long as wide; color yellowish brown. Frons convex, eyes rather widely separated by 2.5 times width of an eye; surface of frons reticulate above, smooth, shining below; punctures sparse above, more numerous on epistomal margin; vestiture sparse, hairlike, longer on epistoma. Pronotum 1.6 times as long as wide, anterior margin acutely projecting cephalad, its apex armed by a pair of large, slender serrations; summit slightly anterior to middle, anterior slope moderately asperate; posterior areas smooth, shining, sparse punctures minute. Elytra 2.4 times as long as wide, 1.4 times as long as pronotum; disc occupying basal half; striae not impressed, punctures very small; interstriae about four times as wide as striae, smooth, shining, punctures minute, uniseriate. Declivity gradual, its lower half strongly concave with lateral margins acutely elevated and armed by 3 major, paired denticles and at least 3 minor unpaired denticles; interstriae 1 and 2 with a few small denticles on basal third; path of striae 1 impressed to apex of declivity, punctures not indicated; surfaces mostly shining in concave area, punctures very small, obscure. Vestiture of fine, long hair, confined to sides and declivity, moderately abundant in concave area.

Distribution: Costa Rica to Brazil and Peru.

Costa Rica: La Selva Biological Station, Heredia, I, II, VIII, IX-1998, 50–150 m canopy lighttraps, secondary forest.

Brazil: "AR, 18-XI-1992, J.B. Silva." Maranhao, Pedrinhas, Sao Luis Island, BL trap, E.C. Bergmann; Sao Paulo, Filtro, Martins (Bright 1991:26). Parana: Marituba, Num. Ananindeua; Sao Nicolau Farm, Cotriguacu, Mato Grosso do Sul, VI-2002, ethanol trap, P. Filho.

Peru: Vic. of Leonpampa, Dep. Huanuco, 11-30-XII-1937, jungle, 800 m, No. 3811, F. Woytkowski.

Notes: The above treatment was based on 1 specimen from Peru and 4 from Brazil, including the female holotype.

GENUS *DRYOCOETOIDES* HOPKINS

Dryocoetoides Hopkins, 1915:52. Type-species: *Dryocoetoides guatemalensis* Hopkins = *Xyleborus capucinus* Eichhoff, original designation

Diagnosis: Distinguished from other American genera of Xyleborini by the inflated protibia, with posterior face inflated and armed by numerous, confused, small tubercles, metatibia usually with eight or nine socketed denticles; and by antennal club segment 2 usually forming a complete, oblique annulus, on anterior face its apical margin acutely costate as on segment 1.

Description: Body of female rather slender to moderately stout, 2.1–5.3 mm; color reddish brown to almost black. Male dwarfed, deformed, flightless. Eye rather large, moderately to coarsely faceted, deeply emarginate; antennal club subcircular, flattened, subcorneous basal area thickened, segment 2 forming a complete, oblique annulus, its apical margin acutely

costate as on segment 1 (both sutures show on posterior face). Pronotum about as long as wide; summit near middle; anterior slope moderately asperate, anterior margin armed by serrations. Elytra elongate, weakly striate, interstitial punctures usually confused; declivity convex, its ventrolateral margin marked by a crest from suture to interstriae 8. Protibia inflated, armed by numerous, confused small tubercles. Male dwarfed, modified, flightless, rare; anterior slope of pronotum impressed to excavated, anterior margin acutely elevated on a continuous

crest varying to a median tuberculate prominence; protibia not inflated or armed on its posterior face.

Distribution: Wood & Bright (c1992:656–659) report 25 species from South America, 3 of which extend into Central America and Mexico, 2 in the Antilles Islands, and 1 introduced into Africa.

Biology: All species are xylomycetophagous and in-breed polygynous. They breed mostly in unthrifty, injured, or cut stems larger than 3 cm and, apparently, smaller than 10 cm in diameter.

Key to the Species of *Dryocoetoides*

- 1. Body stout, 2.0–2.3 times as long as wide; punctures on elytral disc small, confused, striae punctures on surface not in identifiable rows (sometimes evident on declivity; mature color black 2
- Body more slender, at least 2.5 times as long as wide; striae punctures on disc in identifiable rows; mature color reddish brown 6
- 2(1). Punctures on declivital striae 1–6 shallow, clearly evident (not including a tubercle) 3
- Strial punctures on declivity not clearly evident, replaced by tubercles 4
- 3(2). Larger; elytral declivity occupying 50 percent of elytral length, mostly or entirely shining, striae punctures distinctly, shallowly impressed, granules on 2–7 mostly uniseriate except near base; crenulations on ventrolateral margin extending anteriorly to level of suture between abdominal segments 2 and 3; Mexico (Veracruz) to Colombia and Venezuela; 2.8–3.2 mm *monachus* (Blandford)
- Smaller; elytral declivity occupying 60 percent of elytral length, surface strongly reticulate, dull, striae punctures obscure to obsolete, interstitial tubercles confused on basal two-thirds; crenulations on ventrolateral margin of declivity extending to level of abdominal sterna 1 and 2; Mexico (Nayarit, Veracruz) to Brazil and Peru; 2.2–2.6 mm *capucinus* (Eichhoff)
- 4(2). Declivity steeper, occupying 57 percent of elytral length; declivity with weak groove at position of striae 1 and part of 2; tubercles uniseriate on lower interstriae 2 and on 3 immediately above ventrolateral crest; Venezuela (Amazonas) to Suriname and Brazil; 3.3–3.6 mm *granulicauda* (Eggers)
- Declivity more gradual, occupying at least 65 percent of elytral length; tubercles on lower declivity entirely confused (none in uniseriate rows) 5
- 5(4). Punctures of pronotum disc smaller, less deeply impressed; surface of elytral disc much smoother, more brightly shining; position of declivital striae 1 on lower half distinctly impressed; tubercles on declivity distinctly larger; Venezuela (Barinas); 3.3 mm *pileatus* Wood
- Punctures on pronotum disc larger, deeper; surface of elytra disc with impressed lines, surface not as smooth; position of lower striae 1 on declivity not impressed, as high as 1 or 3; tubercles on declivity much smaller; Ecuador; 2.6–2.7 mm *versutus* Wood
- 6(1). On elytral declivity all striae and interstitial punctures replaced by tubercles, these tubercles confused, not in rows; disc occupying basal two-thirds of elytral length; vestiture moderately short, rather abundant on striae and interstriae; Brazil (Guanabara); 2.7 mm *inaffectatus* (Schedl)
- Punctures on declivital striae clearly indicated, in rows 7
- 7(6). Interstitial tubercles on at least basal two-thirds of declivity numerous, strongly confused on 1 and 3 8

- Interstitial tubercles on declivity mostly in uniseriate rows except sometimes confused near base; mostly smaller species 10
- 8(7). Smaller species; punctures on declivital striae 1 and 2 rather large, adjacent interstriae less than twice as wide as striae; declivity broadly, evenly convex, weakly protuberant near apex of 1; ventrolateral margin acutely costate; Brazil (Santa Catarina); 1.8–2.3 mm *truncatellus* (Schedl)
- Larger species, 3.7–5.7 mm; strial punctures on declivity mostly smaller, ventrolateral margin shorter, less distinctly carinate 9
- 9(8). Declivital interstriae 1 and 2 shining, with tubercles strongly confused, 2 strongly constricted below and obsolete before apex, tubercles on 3–5 uniseriate; interstriae 2 at base moderately, obtusely elevated into a prominence (not armed), a moderate sulcus on upper third on 1 and part of 2; anterior margin of pronotum armed by 10–12 serrations; Venezuela (Barinas); *Eschweilera subglandulosa*; 5.7 mm *severus* Wood
- Declivital interstriae 1–5 reticulate with tubercles confused, 2 without an elevated prominence at base or a constriction near apex; smaller species; Venezuela (Bolivar) to Brazil (Espirito Santo, Mato Grosso); 3.7–3.8 mm *rusticus* Wood
- 10(7). Declivital interstriae 1 normal, tubercles uniseriate 11
- Interstriae 1 on lower half of declivity conspicuously expanded (and sometimes slightly elevated), tubercles in expanded area strongly confused, striae 1 and 2 diverge strongly near apex toward suture 18
- 11(10). Declivital interstriae 3 moderately elevated, convex on lower half, joining ventrolateral margin, 2 weakly impressed, constricted and obsolete before apex, devoid of tubercles on lower half, 1 feebly elevated, usually joining ventrolateral margin, tubercles of 1 and 3 moderately coarse, about equal in size and number; Brazil (Santa Catarina); 2.5–2.6 mm *solitarinus* (Schedl)
- Declivital interstriae 3 not conspicuously elevated more than 2, with 2 continued to its usual apex, 1 sometimes elevated 12
- 12(11). Punctures of declivital interstriae 1 and 2 clearly impressed, declivital surface between punctures and tubercles smooth, shining 13
- Punctures of declivital interstriae 1 and 2 obscure to obsolete, areas between punctures and tubercles smooth to reticulate to rugose-reticulate 14
- 13(12). Body stouter, 2.4 times as long as wide; disc occupying slightly more than basal half of elytral length; anterior margin of pronotum costate, feebly serrate; tubercles on declivital interstriae 1 and 2 uniseriate, small, more widely spaced, moderately confused on apical half of 1; Brazil (Para); 2.3 mm *paradoxus* (Schedl)
- Body more slender, 2.7 times as long as wide; disc occupying two-thirds of elytra length; anterior margin of pronotum rather coarsely serrate; tubercles on declivital interstriae 1 and 2 slightly larger, closer; elytral declivity more narrowly convex, brightly shining; tubercles on lower declivital interstriae 1 mostly uniseriate; Venezuela to Trinidad and Brazil; 2.3–2.6 mm *flavus* (Fabricius)
- 14(12). Declivital striae distinctly, equally impressed, interstriae 1 distinctly elevated, tubercles on all interstriae distinctly larger 15
- Declivital striae weakly or not impressed, interstitial tubercles small to obsolete 16
- 15(14). Declivital striae 1 and 2 more distinctly impressed, interstriae 2 and 3 equally, weakly convex and finely serrate, 1 slightly more strongly elevated from base almost to apex, crest weakly subserrate; ventrolateral margin of declivity acutely costate; Brazil (Mato Grosso); 2.8 mm *semicostatus* (Schedl)

- Declivital striae less strongly impressed, tubercles on interstriae 2 and 3 feebly convex, tubercles larger, more definite, closer, 1 more strongly, broadly elevated on central two-thirds of declivity length, crest granular, tubercles indefinite; Venezuela (Barinas); 2.5 mm *verrucosus* Wood
- 16(14). Declivital striae weakly impressed, interstitial tubercles rather small, interstriae 1 without a shallow sulcus on lateral half near apex; Brazil (Minas Gerais); 2.2 mm *vexans* (Schedl)
- Declivital striae not impressed, tubercles very small to obsolete; declivital interstriae 1 with a shallow sulcus on lateral half near apex 17
- 17(16). Declivity occupying 45 percent of elytral length, steeper, more strongly convex; disc of pronotum moderately reticulate; Antilles Islands and Venezuela to Guiana and Brazil; 2.4–2.8 mm *psudosolitarius* (Eggers)
- Declivity more gradual, occupying slightly more than half of declivital length, more broadly convex; disc of pronotum smooth, shining; Africa, Antilles Islands, Venezuela and Trinidad to Brazil; 2.6–3.0 mm *cristatus* (Fabricius)
- 18(10). Body smaller, more slender, 2.9 times as long as wide; ventrolateral costa of declivity forming a complete circumdeclivital ring, interstitial tubercles restricted to declivity inside costate ring; Brazil (Santa Catarina) to Paraguay; 2.7–2.8 mm *obtusitruncatus* (Schedl)
- Body stouter, less than 2.7 times as long as wide; two-thirds of basal margin of declivity rounded, subcostate on less than lower fourth 19
- 19(18). Elytral declivity rugose-reticulate, dull; declivital striae less strongly impressed, punctures shallowly impressed; ventrolateral costa on declivity slightly higher, longer 20
- Elytral declivity subshining, reticulation obscure; declivital striae distinctly to moderately impressed; ventrolateral costa on declivity shorter, less distinct, sometimes obscure 21
- 20(19). Strial punctures on disc small, most equal in size to those of interstriae, some obsolete; tubercles on basal half of declivital interstriae 8 distinctly smaller than those of 9; Venezuela (Palmar); 2.8–3.0 mm *velutinus* Wood
- Strial punctures in distinct rows, impressed, almost twice as large as those of interstriae; tubercles on basal half of declivital interstriae 8 at least equal in size to those of 9; Venezuela (Palmar); 3.7–3.8 mm *indolatus* Wood
- 21(19). Declivital sculpture occupying more than basal half of elytra, striae strongly impressed on basal half of declivity, punctures rather small, shallow; interstriae on basal half of declivity each armed by a row of rather coarse tubercles, becoming much smaller on lower half; Colombia; *Humiristrum excelsum*; 4.7–4.9 mm *insculptus* Wood
- Declivital sculpture restricted to posterior 40 percent of elytral length; striae weakly to moderately impressed; interstitial tubercles on declivity smaller, confused 22
- 22(21). Declivital tubercles on interstriae 1 and 2 mostly confused on basal two-thirds; strial punctures on declivity moderately large; Brazil (Sao Paulo); 3.7 mm *alter* (Eggers)
- Declivital tubercles on interstriae 1 and 2 mostly uniseriate on basal two-thirds; strial punctures on declivity very small; “Mexico,” Costa Rica to Brazil; 3.5–4.3 mm *asperulus* (Eggers)

Dryocoetoides monachus (Blandford)

Plate LXXXIII

Dryocoetoides monachus (Blandford), 1898:204 (*Xyleborus*). Lectotype ♂; Cerro Zunil, Guatemala; BMNH, London, designated by Wood 1982:764 (References in Wood & Bright c1992:658)

Diagnosis: Distinguished from *capucinus* (Eichhoff) by the larger size; by the shorter, steeper, shining elytral declivity, with strial punctures distinctly impressed, granules on interstriae 2–7 mostly uniseriate, costa of ventrolateral margin longer.

Male: Not at hand, type in BMNH, London.

Female: Length 2.8–3.2 mm, 2.4 times as long as wide; color black. Frons broadly convex, rather strongly reticulate and moderately punctured on upper half, obscurely reticulate below, with numerous tubercles from epistoma almost to upper level of eyes; hairlike setae sparse on lower half, more numerous and longer on epistomal margin. Pronotum essentially as in *capucinus* (below). Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; declivity occupying about 50 percent of elytral length; surface of disc and upper half of declivity smooth, shining, lower half of declivity often dull, subreticulate in some specimens; interstrial granules on declivity mostly uniseriate, crenulations on interstriae 8 begin about middle of declivity.

Distribution: Mexico (Veracruz) to Colombia and Venezuela.

Colombia: 24 km E Barbosa, Antioquia, 18-VII-1970, 1200 m, No. 696, Rubiaceae, SLW.

Venezuela: El Laurel Experimental Farm, 12 km SW Caracas, 1-V-1970, 1300 m, No. 460, tree limb, SLW; Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 420, *Tabebuia*, SLW

Hosts: *Inga* sp., *Tabebuia* sp., etc.

Biology: As in *capucinus*.

Notes: The above treatment was based on 1 specimen from Colombia and 20 from Venezuela, all females. The male lectotype was examined (Wood 1982:764) and was compared to females taken in Guatemala.

Dryocoetoides capucinus (Eichhoff)

Plate LXXXI

Dryocoetoides capucinus (Eichhoff), 1869:281 (*Xyleborus*). Holotype ♀; Guadeloupe Island; IRSNB, Brussels (Synonymy and references in Wood & Bright c1992:656)

Xyleborus rufithorax Eichhoff, 1869:281. Holotype ♀; Brazil; IRSNB, Brussels

Dryocoetoides guatemalensis Hopkins, 1915:52. Holotype ♀; Livingston, Guatemala; USNM, Washington

Xyleborus capucinoides Eggers, 1941:104. Holotype ♀; Gourbeyere, Guadeloupe Island; USNM, Washington

Diagnosis: Distinguished by the stout body; by the confused striae and interstrial punctures on the disc; by the strongly reticulate declivity that occupies 60 percent of the elytral length; and by other characters included in the above key.

Male: Length 2.2–2.5 mm, head and elytra about as in female but less perfectly formed; pronotum 1.4 times as long as wide, devoid of asperities, summit near base, middle third flattened on median half, anterior third deeply excavated to lateral and anterior margins, anterior margin sharply elevated, with a median tuberculate prominence.

Female: Length 2.2–2.6 mm, 2.4 times as long as wide; mature color black. Frons about as in *monachus* (Blandford) except punctures and tubercles smaller; eyes separated by 3.0 times width of an eye. Pronotum 0.96 times as long as wide, anterior margin rather

broadly rounded, slightly produced at median area. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; disc occupying 40 percent of elytra length; striae scarcely evident, punctures very small, distinct, spaced by two diameters of a puncture, interstriae smooth, almost shining, six to eight times as wide as striae, setiferous punctures slightly smaller than those of striae. Declivity rather gradual, entirely reticulate; striae weakly impressed, punctures obscure to obsolete, when visible, shallow and larger than on disc, interstrial punctures replaced by fine, confused granules, sometimes uniseriate on apical half of 2 and 3, with 8 subcrenulate granules from near base of declivity to sutural apex. Vestiture of abundant, moderately long hair, fine on disc, usually coarser on declivity.

Distribution: Mexico (Nayarit, Veracruz) and Guadeloupe Island to Peru and Brazil.

Brazil: Cited in Eichhoff (1869:281) and Wood & Bright (c1992:656–657).

Colombia: 24 km E Barbosa, Antioquia, 18-VII-1970, 1200 m, No. 696, Rubiaceae sp., SLW.

Guiana: Cited in Wood & Bright (c1992:656).

Peru: Dept. San Martin Almirante, 12-XII-1936, 1900 m, No. 3737, subtropical forest, F. Woytkowski.

Venezuela: Cited in Wood & Bright (c1992:656).

Hosts: *Inga* sp., *Miconia* sp., Rubiaceae sp., etc.

Biology: Breeds in cut, broken, or unthrifty branches about 3–7 cm in diameter. A radial entrance tunnel extends 1 to 2 cm into the wood where it diverges across the grain of wood to transversely follow a growth ring around the stem. The pattern often forms a complete circle and may rejoin the original (radial) entrance tunnel.

Notes: The above treatment was based on 43 specimens from Mexico and Central America, on 31 from Colombia, and on 2 from Peru. The female holotype of *Xyleborus capucinus* Eichhoff, *X. rufithorax* Eichhoff, *X. capucinoides* Eggers, and *Dryocoetoides guatemalensis* Hopkins were also examined and compared to my series.

Dryocoetoides granulicauda (Eggers)

Dryocoetoides granulicauda (Eggers), 1931:22 (*Xyleborus*). Holotype ♀; Camopi, French Guyane; Hamburg Museum, lost, cotype in NHMW, Wien (Synonymy and references in Wood & Bright c1992:657)

Xyleborus rufithorax nigricollis Hagedorn, 1905:2. Holotype ♀; Camopi, French Guyane; MNHN, Paris; cited as a synonym by Eggers (1933:3); type not available for loan for confirmation

Diagnosis: Distinguished from *capucinus* (Eichhoff) by the obscure striae punctures (disc), most of which are replaced on the declivity by tubercles; and by the larger size.

Female: Length 3.3–3.6 mm, 2.2 times as long as wide; mature color black. Frons and pronotum about as in *monachus* (Blandford). Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; disc occupying basal 40 percent of elytral length, transition to declivity rather abrupt; disc smooth, shining, striae not impressed,

punctures very small, not larger than those of interstriae, partly confused (at least near base). Declivity somewhat abrupt at its base, strongly reticulate, less strongly arched than in *monachus*; striae not indicated, surface armed by numerous, confused, subacutely pointed tubercles; ventrolateral margin to interstriae 9 subacutely elevated, rather coarsely serrate (longer and more prominent than in *monachus*); vestiture similar to *monachus*, but slightly recumbent.

Distribution: French Guyane to Venezuela and Brazil.

Brazil: San Nicolau Farm, Cotriguacu, Mato Grosso do Sul, VI-2002, rain forest, ethanol trap, P. Filho.

French Guyane: Comopi.

Venezuela: Amazonas, 1975, No. 24, E.F. Bruning.

Notes: The above treatment was based on 1 female in my collection from Venezuela that was identified by me in 1974. My notes indicate that it was compared to an Eggers specimen, but an official record was not made. The female holotype of *Xyleborus rufithorax* Hagedorn was examined and is identical to my specimen.

Dryocoetoides versutus Wood, n. sp.

Dryocoetoides versutus Wood: Holotype ♀; Napo Mirahualli near Tena, Ecuador; USNM, Washington, designated below

Diagnosis: Distinguished from *pileatus* Wood by the much smaller tubercles on the declivity; by the absence of an impression on the lower half of declivital interstriae 1; by the larger punctures on the elytral disc and impressed lines between punctures; by the smaller punctures on the pronotum disc; and by the smaller size.

Female: Length 2.6–2.7 mm, 2.3 times as long as wide; color very dark reddish brown to almost black. Frons broadly convex eye to eye from epistoma to vertex; reticulate above upper level of eyes, smooth below; small moderately close punctures on upper half gradually replaced by small, rounded tubercles on lower third; vestiture very sparse except epistomal brush with numerous rather long setae. Pronotum 1.0 times as long as wide; widest near middle of pronotum length, sides rather weakly arcuate on posterior two-thirds, rather narrowly, subangulately rounded in front; anterior margin armed by 4 serrations on less than central fourth, median pair largest; summit near middle of pronotum length; asperities rather coarse, close, confused; surface behind summit almost smooth, becoming moderately then strongly reticulate laterally, punctures moderately coarse, deep, close; vestiture of moderately coarse long setae at margins, less abundant and shorter toward declivity. Elytra 1.15 times as long as wide, 1.15 times as long as pronotum; disc occupying 38 percent of elytra length; disc smooth, shining, punctures small, confused, with impressed irregular lines. Declivity rather steep, moderately convex; surface minutely rugose-reticulate, punctures of striae 1 minute (and with granules), others obsolete, striae and interstriae with numerous confused, small granules; without any impression or elevated areas;

ventrolateral margin marked by a closely set row of small cusps, ending below middle of declivity length. Vestiture of moderately abundant short, coarse setae of a mixture of very short and moderately short length. Protibia inflated on posterior face and armed by several small tubercles.

Distribution: Ecuador.

Type material: The female holotype and 1 female paratype were taken at Napo Mirahualli near Tena, Ecuador, 3-8-XI-1999, at light S.R. Keller. The holotype and paratype are in the U.S. National Museum, Washington.

Dryocoetoides pileatus Wood

Plate LXXXIV

Dryocoetoides pileatus Wood, 1974:29. Holotype ♀; 40 km SE Socopo, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:658)

Diagnosis: Distinguished from *granulicauda* (Eggers) by the longer, more gradual elytral declivity; by the weak declivital groove at position of striae 1; by the confused tubercles on the lower declivity; and by the almost uniformly short declivital setae.

Female: Length 3.3 mm, 2.1 times as long as wide; mature color dark reddish brown to black. Frons, pronotum, and general shape and contour of elytra about as in *granulicauda*. Elytral disc occupying 31 percent of elytral length, striae punctures on disc very small but in distinct rows, punctures distinctly larger than those of interstriae; a distinctly impressed sulcus on most of lower half of striae 1 (punctures not evident); tubercles arming declivity smaller and of more uniform size than in *granulicauda*, crest of ventrolateral margin weakly elevated, very weakly serrate.

Distribution: Venezuela: 10 km SE Miri, Barinas, 8-II-1970, 150 m, No. 295, *Inga*, SLW; 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 263, *Inga*, SLW; 3 km NE Creole, Barinas, 18-XII-1969, 150 m, No. 203, *Inga*, SLW.

Hosts: *Inga* sp., 1 from a small palm stem. It is considered a roosting record only.

Notes: The above treatment was based on the type series of 8 specimens from Venezuela.

Dryocoetoides inaeffectatus (Schedl)

Dryocoetoides inaeffectatus (Schedl), 1972:71 (*Xyleborus*). Holotype ♀; Repressa, Rio Grande, Guanabara, Brazil; NHMW, Wien (References in Wood & Bright c1992:658)

Diagnosis: This is the only known species in this genus having the striae punctures on the disc in uniseriate rows and those on the declivity replaced by confused tubercles.

Female: Length 2.7 mm, 2.6 times as long as wide; color dark reddish brown, elytra darker. Frons broadly convex, an obscure median fovea at center; surface reticulate, coarsely, closely punctured on upper half, lower half with rather numerous rounded granules, a few

punctures laterally; vestiture hairlike, moderately abundant on lower third, rather long. Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal two-thirds, broadly rounded in front; anterior margin feebly armed by 10 weak serrations; summit at middle, anterior slope rather coarsely, closely asperate; posterior areas smooth, shining, punctures small, moderately close; vestiture hairlike, rather abundant, moderately long. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; disc occupying basal two-thirds of elytra length; striae not impressed, small punctures in obscure rows; interstriae four times as wide as striae, almost smooth, shining, small punctures half as large as those of striae, confused, some of those near declivity replaced by small tubercles. Declivity broadly convex, steep, base rounded; striae 1 and 2 indicated only near base, tubercles strongly confused below and laterally, tubercles conical, as wide as long, of uniform size, rather abundant; slightly protruding on interstriae 1 near apex; ventrolateral margin acutely costate, rather long. Interstitial setae of fine, moderately long, confused hair.

Distribution: Brazil: Guanabara, Represa Rio Grande, III-1970, F.M. Oliveira.

Notes: The above treatment was based on the female holotype from Brazil.

Dryocoetoides truncatellus (Schedl)

Dryocoetoides truncatellus (Schedl), 1948:272 (*Xyleborus*). Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, present designation (References in Wood & Bright c1992:658)

Diagnosis: Distinguished from *inaffectatus* (Schedl) by having declivital striae 1 and 2 in closely marked rows of rather large punctures, interstitial tubercles mostly in rows; by the surface of the declivity being mostly, weakly reticulate; and by the small size.

Female: Length 1.8–2.3 mm, 2.9 times as long as wide; color reddish brown. Frons about as in *inaffectatus*, except fovea obscure to absent. Pronotum 1.1 times as long as wide; similar to *inaffectatus*, except anterior margin armed by 6 rather coarse serrations, basal areas behind summit strongly reticulate, punctures rather small, deep, close. Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; disc occupying basal 80 percent of elytra length; striae not impressed, punctures small, shallow; interstriae about four times as wide as striae, punctures minute to obsolete, confused near declivity, mostly uniseriate anteriorly. Declivity base rather abrupt, steep, broadly convex; punctures of striae 1 and 2 greatly enlarged, distinctly impressed, in rows; interstriae 1 and 2 with punctures replaced by small pointed tubercles, almost uniseriate above, moderately confused below; surface weakly subreticulate; interstriae 1 slightly protuberant near apex; ventrolateral margin acutely subcostate, crest partly, weakly serrate. Vestiture of fine, rather short, sparse interstitial hair.

Distribution: Brazil: Nova Teutonia, Santa Catarina, 1944, F. Plaumann.

Notes: The above treatment was based on the syntype Schedl (1979:257), subsequently labeled as the “holotype,” and on 6 female syntypes Schedl labeled as “paratypes,” from Brazil. Because his designations were invalid under the International Code on Zoological Nomenclature, I here designate that “holotype” as the female lectotype, and the 6 “paratypes” as lectoparatypes of *Xyleborus truncatellus* Schedl, as indicated above.

Dryocoetoides severus Wood

Dryocoetoides severus Wood, 1974:30. Holotype ♀; 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:658)

Diagnosis: Distinguished by the large size; by the almost subquadrate pronotum; by the short, steep elytral declivity, with punctures on striae 1 and 2 and an elevation at base of declivital interstriae 2; and by other characters described below.

Female: Length 5.7 mm, 2.9 times as long as wide, color dark reddish brown. Frons about as in previous species. Pronotum almost quadrate, anterior margin poorly armed in median area. Elytra 1.6 times as long as wide, 1.2 times as long as pronotum; disc occupying basal 70 percent of elytra length; striae not impressed, punctures small, shallow, in rows; interstriae smooth, shining, about five times as wide as striae, punctures almost as wide as those of striae, rather numerous, confused, those on anterior half replaced by rounded tubercles. Declivity short, steep; interstriae 2 at base of declivity obtusely elevated, shallowly impressed near base between these elevations; striae 1–8 with small, shallowly impressed punctures, interstriae each armed by a row of rounded granules except confused on 1; ventrolateral margin obtusely elevated to interstriae 9. Vestiture of fine, long, rather abundant interstitial setae on posterior half of elytra length, striae setae much shorter.

Distribution: Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 548, *Eschweilera subglandulosa* in rain forest, SLW.

Notes: The above treatment was based on the female holotype.

Dryocoetoides rusticus Wood

Plate LXXXV

Dryocoetoides rusticus Wood, 1974:30. Holotype ♀; Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:658)

Xyleborus haesitus Schedl, 1976:74. Holotype ♀; Ter. Ampara, Serra Navio, Brazil; NHMW, Wien (References in Wood & Bright c1992:742). *New synonymy*

Diagnosis: Distinguished by the short, steep declivity, with striae punctures on 1–3 clearly indicated.

Female: Length 3.7–3.8 mm, 2.6 times as long as wide; color reddish brown. Frons similar to previous species. Pronotum 1.1 times as long as wide; anterior margin procurved and armed by 6 serrations; summit rounded, at middle of pronotum length; disc smooth, shining, punctures small, shallow, moderately abundant; vestiture

sparse, hairlike, rather sparse. Elytra 1.5 times as long as wide, 1.2 times as long as pronotum; disc occupying basal half of elytra length; striae not impressed, punctures small, distinct, uniseriate; interstriae five times as wide as striae, smooth, shining, punctures minute, confused, moderately abundant. Declivity steep, very broadly convex, reticulate (weakly above, almost rugose-reticulate below); striae punctures twice as large as on disc; interstitial punctures replaced by rather numerous, confused, subacutely pointed tubercles of rather small size from base almost to apex; ventrolateral costa low, subacute from suture to level of interstriae 3, interstriae 8 moderately serrate from near end to ventrolateral costa (not connected to costa) cephalad to near base of declivity. Vestiture moderately abundant on declivity, confused, consisting mostly of rather short, somewhat stout hair and (on basal half) a few fine, long, hairlike setae.

Distribution: Brazil to Venezuela.

Brazil: Espirito Santo, Aracruz, 12-III-1993, 5250, C.A.H. Flechtmann; RS/RGS Expedition 12°31'S, 51°46'W, 4-XII-1968, E3, 1/1, R.A. Beaver; Ter. Ampara, Serra Navio, Bicellicol.

Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, rain forest, No. 582, SLW (type).

Notes: The above treatment was based on 2 females of *Xyleborus haesitus* Schedl from Brazil from the Schedl series, and on the female holotype of *Dryocoetoides rusticus* Wood from Venezuela.

Dryocoetoides solitarinus (Schedl)

Dryocoetoides solitarinus (Schedl), 1950:178 (*Xyleborus*). Lectotype ♀; Rio Claro, Brazil; NHMW, Wien, designated by Schedl 1979:232 (References in Wood & Bright c1992:658)

Diagnosis: Distinguished from other members of this genus by the unique declivity on which declivity interstriae 2 is strongly constricted to obsolete and interstriae 3 is convexly elevated on the lower half.

Female: Length 2.5–2.6 mm, 2.7 times as long as wide; color dark reddish brown. Frons broadly convex, strongly reticulate from epistoma to vertex; punctures very small, obscure, a few granules on lower fourth; sparse hairlike vestiture mostly on or near epistoma. Pronotum 1.1 times as long as wide; about as in *inaffectatus* (Schedl) except anterior margin armed by 8 serrations; basal area strongly reticulate, punctures moderately coarse, close; vestiture hairlike, moderately abundant, mostly on margins. Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; disc occupying basal 60 percent of elytra length; striae not impressed, punctures rather coarse, deep; interstriae three times as wide as striae, almost smooth, shining, a few impressed lines, punctures less than half as large as those of striae, mostly uniseriate on 1 and 3, mostly confused on 2 and 4. Declivity moderately steep; striae 1–3 clearly marked by punctures; interstriae 1 and 3 weakly convex at base, more strongly convex below, each armed by a row of rather coarse,

closely placed denticles from base to apex, 2 armed by denticles on basal third, constricted and obsolete on lower half; a few smaller tubercles on 4 6. Vestiture of minute striae hair and erect interstitial setae of moderate abundance, rather short.

Distribution: Brazil: Nova Teutonia, Santa Catarina, 6-XII-1947, IV-1955, X-1966, F. Plaumann.

Notes: The above treatment was based on the female lectotype and 5 female lectoparatypes from Brazil.

Dryocoetoides paradoxus (Schedl)

Dryocoetoides paradoxus (Schedl), 1972:71 (*Xyleborus*). Holotype ♀; Jacareacanga, Para, Brazil; NHMW, Wien (Synonymy and references in Wood & Bright c1992:658)

Xyleborus solitaripennis Schedl, 1976:77 (*Xyleborus*). Holotype ♀; Maturaca AM, alto Rio Canaburi; NHMW, Wien

Diagnosis: Distinguished from other members of this genus by the comparatively stout body form; by the costate anterior margin of the pronotum; and by the simple elytral declivity.

Female: Length 2.3 mm, 2.3 times as long as wide; color reddish brown. Frons apparently as in *inaffectatus* (Schedl) (partly concealed by pronotum on type). Pronotum 1.08 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded on anterior margin; anterior margin acutely costate on more than median third of pronotum width (not serrate); summit at middle of pronotum length, anterior slope closely, rather coarsely asperate; posterior areas smooth, shining, punctures minute, rather sparse. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; disc occupying basal half of elytra length; striae not impressed, punctures rather small, in distinct rows; interstriae three to four times as wide as striae, smooth, shining, uniseriate punctures half as large as those of striae (not granulate near declivity). Declivity broadly convex, steep; striae 1–3 not impressed, clearly marked by moderately large punctures (almost twice as large as those on disc); interstriae 1 and 2 on basal half as wide as striae, smooth, shining, 2 and 3 each with a uniseriate row of very small tubercles, 1 with similar, closer tubercles on basal half, closer and confused below, distinctly protuberant near apex; ventrolateral costa acutely, uniformly elevated from suture to interstriae 7. Vestiture of fine striae and interstitial hair of about equal, moderate length, rather abundant.

Distribution: Brazil: Jacareacanga, Para, IX-1970, ER. Barbosa.

Biology: Type apparently attracted to light (numerous loose moth scales on elytra of type).

Notes: The above treatment was based on the female holotype from Brazil.

Dryocoetoides flavus (Fabricius)

Plate LXXXII

Dryocoetoides flavus (Fabricius), 1801:394 (*Hylesinus*). Syntypes 2♂♂, 2♀♀; types labeled Essiquibo [River, in Guiana], published as *America meridionali*; UZMC, Copenhagen (References in Wood & Bright c1992:657)

Diagnosis: Distinguished from *verrucosus* Wood by the smooth (not rugose-reticulate) surfaces of the elytral declivity; by the clearly impressed stria punctures on the declivity; and by the declivital interstriae 1 sculptured as 2–8 (not elevated or acutely serrate).

Male: Two *Dryocoetoides* males were taken from an otherwise empty, used tunnel in Venezuela (Miri). The size, location, and general characters suggest that they are males of *D. flavus* (Fabricius). They are described as follows: Length 2.6 mm, 2.6 times as long as wide, color yellowish brown. Frons about as in female except a weak central fovea present in both (in 1 this fovea partly occupied by a minute tubercle; in a second specimen a weak sulcus extending from fovea toward epistoma). Pronotum 1.1 times as long as wide; indefinite summit anterior to middle, anterior margin more narrowly rounded and feebly emarginate on median sixth, anterior slope moderately declivous, asperities reduced to minute granules (spaces between smooth, shining); vestiture at and near lateral margins much more abundant and larger than in female. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; disc about as in female except stria and interstitial punctures slightly larger and deeper. Declivity occupying posterior half of elytral length, slightly more gradual than in female, weakly impressed between feebly elevated interstriae 3; striae obscurely punctured, interstriae without punctures or granules. Vestiture hairlike, almost absent on disc, short, rather sparse on declivity, rather long and moderately abundant on sides from base to near apex of declivity. Antenna and protibia as in female.

Female: Length 2.3–2.5 mm, 2.8 times as long as wide; color reddish brown. Frons and pronotum as in *verrucosus* (except pronotum 1.1 times as long as wide). Elytra 1.6 times as long as wide; 1.4 times as long as pronotum; disc as in *verrucosus* except punctures on interstriae 2 and 3 slightly more numerous and confused (others uniseriate). Declivity rather steep, convex; surface smooth, shining (not reticulate); striae 1–8 with punctures twice as large as those on disc, moderately impressed; interstriae 1–8 feebly elevated, each bearing a uniseriate row of subacutely pointed granules (or small tubercles) of equal size from base to near apex. Vestiture of fine, uniseriate rows of interstitial hair on posterior half of elytra, each seta up to twice as long as distance between rows.

Distribution: Venezuela to French Guyane and Trinidad to Brazil.

Brazil: Amazonas, Corcovado N.P., Manaus, 26-XI-1979, G. Stevens; IPNA Campus, Manaus, 31-XII-1986, ethanol trap, G.M. Souza; Lagoas, CPC, Horto Rio Verde, MS, ethanol trap, *Eucalyptus grandis* stand, C.A.H. Flechtmann.

Guiana: Essiquibo River (America Meridionale; Wood 1974:28).

Venezuela: Tortuga Estate, 6-IV-1964, *Theobroma cacao*, J.L. Saunders; 17 km SE Miri, Barinas, 17-XII-1969, 150 m, No. 199, *Bombacopsis quinata*, SLW; 9 km S Barancas, Barinas, 5-XI-1969, 150 m, No. 116, *Inga*,

SLW; 3 km E Creole, Barinas, 18-XII-1969, 150 m, No. 203, *Inga*, SLW, same data from *Trichilia propinqua*; 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 258, “palito negro,” SLW; Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 581, *Brownia*, SLW; Finca Monosterios, Cacaugua, Miranda, 1971, *Theobroma cacao*, J.L. Saunders.

Hosts: *Bombacopsis quinata*, *Brownia* sp., *Inga* sp., *Qualea ingens*, *Theobroma cacao*, *Trichilia propinqua*, *Xylopia* sp.

Notes: The above treatment was based on 2 specimens from Brazil, 4 from Guiana, and 44 from Venezuela. Several of these were compared by me directly to Schedl's series of this species.

Dryocoetoides semicostatus (Schedl)

Dryocoetoides semicostatus (Schedl), 1948:268 (*Xyleborus*). Holotype ♀; Corumba, Alto, Paraguay; NHMW, Wien (References in Wood & Bright c1992:658)

Diagnosis: Distinguished from other known species of this genus by the strongly impressed declivital striae 1–6; and by the convex declivital interstriae from base to apex.

Female: Length 2.8 mm, 2.6 times as long as wide; color yellowish brown (anterior) to reddish brown (posterior). Frons apparently as in *inaffectatus* (Schedl). Pronotum 1.1 times as long as wide; sides weakly arcuate and subparallel on basal two-thirds, rather narrowly rounded in front; anterior margin armed by 6 coarse serrations; summit at middle, anterior slope coarsely, closely asperate; posterior areas shining, almost smooth, surface very weakly reticulate, punctures moderately large, sparse. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; disc occupying basal 60 percent of elytra length; striae not impressed, punctures moderately large, in rows; interstriae two to three times as wide as striae; surface partly smooth, shining, with areas of weak to moderate reticulation, punctures half as large as those of striae, uniseriate. Declivity convex, rather steep; striae 1–6 strongly impressed, punctures obscure to obsolete; interstriae 2–6 moderately convex, each armed by a uniseriate row of fine to obscure denticles from base to apex, 1 more strongly elevated, with tubercles on crest weak to obscure; ventrolateral margin acutely costate and undulating slightly from suture to interstriae 7. Vestiture mostly obsolete, a few minute interstitial setae on disc near base of declivity.

Distribution: Brazil: “Corumba, alto Paraguay, H. Richter, *X. semicostatus* Hagedorn, 1909, cotype.”

Notes: The above treatment was based on the female holotype. This specimen bears the name and label of Hagedorn and Hagedorn's cotype label that indicate it was in the Hamburg Museum until Eggers moved it during World War II to the Eggers Collection (Wood & Bright c1992:2–3).

Dryocoetoides verrucosus Wood

Dryocoetoides verrucosus Wood, 1974:28. Holotype ♀; Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:659)

Diagnosis: Interstitial tubercles on declivity in uniseriate rows, lower half of 1 not expanded, elevated and subserrate on middle two-thirds of elytra length; anterior margin of pronotum armed by eight serrations.

Female: Length 2.5 mm, 3.1 times as long as wide; color reddish brown. Frons convex, obscurely reticulate, upper half obscurely punctured, lower areas with several small, rounded granules; vestiture hairlike, mostly on or near epistoma. Pronotum 1.3 times as long as wide; sides straight and parallel on basal two-thirds, broadly rounded in front, anterior margin armed by 8–10 serrations; summit in front of middle; anterior slope finely, closely asperate; posterior areas smooth, brightly shining, punctures sparse, minute. Elytra 1.8 times as long as wide, 1.4 times as long as pronotum; disc occupying basal 45 percent of elytral length; striae not impressed, except 1 weakly near declivity, punctures small, shallow, uniseriate; interstriae about four times as wide as striae, smooth, shining, punctures about one-third as large as those of striae, uniseriate. Declivity rather steep, convex, surface rugose-reticulate, transition in sculpture abrupt; striae punctures obscure to obsolete; interstriae 2–8 each armed by a row of small, pointed denticles from base to near apex, 1 rather strongly elevated on middle two-thirds of declivital length, acute summit irregularly subserrate. Vestiture largely confined to declivity, consisting of uniseriate rows of short, rather slender hair of uniform length, each seta about as long as distance between rows.

Distribution: Venezuela: 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 579, *Rosada* (Moraceae), SLW (holotype); 3 km NE Creole, Barinas, 18-XII-1969, 150 m, No. 203, *Inga*, SLW (paratype).

Biology: Boring into small stems.

Notes: The above treatment was based on the female holotype (with head and pronotum missing) and on 1 female paratype, with apex of elytra damaged, both from tropical rain forests in Venezuela.

Dryocoetoides vexans (Schedl)

Plate LXXXVI

Dryocoetoides vexans (Schedl), 1972:72 (*Xyleborus*). Holotype ♀; S. Caraca, Barbara, Minas Gerais, Brazil, 1450 m; NHMW, Wien (References in Wood & Bright c1992:659)

Diagnosis: Superficially resembling *flavus* (Fabricius), but slightly smaller, pronotum disc reticulate, elytral declivity shorter, steeper, more broadly convex, outline of posterior profile much more broadly rounded, details of declivital sculpture different.

Female: Length 2.2 mm, 2.6 times as long as wide; color yellowish brown (mature?). Frons similar to *flavus* except less strongly convex. Pronotum 1.1 times as long as wide, resembling *flavus*, except serrations on anterior

margin weak to almost obsolete, surface of disc reticulate. Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; disc occupying 73 percent of elytra length; striae not impressed, punctures small, very shallow; interstriae four times as wide as striae, smooth, shining, uniseriate punctures minute, less than half as wide as those of striae. Declivity rather abrupt at base, steep, broadly convex, posterior profile much more broadly rounded than in *flavus*; striae very weakly impressed, punctures twice as large as on disc, more strongly impressed; interstriae slightly wider than striae, surfaces smooth, shining, with no punctures, 1–3 each with a uniseriate row of rather small tubercles, except tubercles confused on lower half of 1 (and very weakly elevated). Vestiture of fine very short hair on declivity; and erect interstitial setae (mostly obsolete on declivity), mostly in rows and more numerous than in *flavus*, but distinctly shorter.

Distribution: Brazil: S. Caraca, S. Barbara, Minas Gerais, 1450 m, II-1969, F.M. Oliveira.

Notes: The above treatment was based on the female holotype from Brazil.

Dryocoetoides pseudosolitariarius (Eggers)

Plate LXXXV

Dryocoetoides pseudosolitariarius (Eggers), 1933:28 (*Xyleborus*). Holotype ♀; Cayenne, French Guyane; MNHN, Paris (Synonymy and references in Wood & Bright c1992:658)

Xyleborus pseudosolitariarius schizolobus Schedl, 1950:179. Lectotype ♀; Rio Claro, Brazil; NHMW, Wien, designated by Schedl 1979:202

Diagnosis: Distinguished from *flavus* (Fabricius) by the larger size; by the rugose-reticulate elytral declivity; and by the smaller, less regular interstitial tubercles on the declivity.

Female: Length 2.4–2.8 mm, 2.8 times as long as wide; color dark reddish brown. Frons resembling *flavus*. Pronotum about as in *flavus*, disc weakly reticulate. Elytra about as in *flavus* except surface of declivity rugose-reticulate, dull; declivital striae usually with visible punctures, interstitial tubercles smaller, less regular, vestiture slightly less abundant, profile of declivital suture more strongly convex.

Distribution: Antilles Islands to Venezuela.

Antilles Islands: Dominicana: Samana Prov., 15-VIII-1967, L.H. Rolston. Puerto Rico: Mayagoza, Hopk. US 6275, *Inga vera*.

Brazil: Cepec, Ilheus, Bahia, 1966–1968, at light.

French Guyane: Cited in Wood & Bright (c1992:638).

Venezuela: 9 km S Barancas, Barinas, 1-X-1969, 150 m, No. 28, *Cassia fistula*, SLW; Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 579, *Rosada* (Moraceae), SLW.

Hosts: *Cassia fistula*, *Eucalyptus excelsum*, *Gleditsia*, *Hirtella glandulosa*, *Inga vera*, *Rosada*.

Biology: Boring in small stems 2–5 cm in diameter.

Notes: The above treatment was based on 7 females, 2 of which were from the Antilles Islands, 1 from Brazil, and 4 from Venezuela. One female from Venezuela was

compared by me directly to the holotype of *Xyleborus pseudosolitarium* Eggers.

Dryocoetoides cristatus (Fabricius)

Plate LXXXI

Dryocoetoides cristatus (Fabricius), 1801:389 (*Bostrichus*). Holotype ♀; labeled Essiquibo [River, Guiana], published as America Meridionali; UZMC, Copenhagen (Synonymy and references in Wood & Bright c1992:657)

Xyleborus solitarium Hagedorn, 1905:415. Holotype ♀; Camopi, French Guiana; MNHN, Paris (♀)

Xyleborus urichi Sampson, 1912:245. Holotype ♀; Trinidad; BMNH, London

Dryocoetoides caracicolai Hopkins, 1915:53. Holotype ♀; Port of Spain, Trinidad; USNM, Washington (References in Wood & Bright c1992:657). *New synonymy*

Xyleborus crenatus Eggers, 1920:42. Lectotype ♀; Kangu; USNM, Washington, designated by Anderson & Anderson 1971:10

Diagnosis: Distinguished from *pseudosolitarium* (Eggers) by the larger average size; by the more shining pronotum disc; and by the convex, more gradual elytral declivity with stria punctures obsolete.

Female: Length 2.6–3.0 mm, 2.8 times as long as wide; color dark reddish brown. Frons and pronotum about as in *pseudosolitarium*, except disc of pronotum usually mostly or entirely smooth, shining; punctures of declivital striae very shallow but usually present; interstriae 1 much more strongly, broadly impressed on middle half of declivity, profile of declivital suture less strongly convex, almost straight in some specimens.

Distribution: Africa (introduced to Angola, Cameroon, Congo, Fernando Poo, Gabon, Ghana, Ivory Coast, Nigeria, Sao Tome Island, Uganda, Zaire), Antilles Islands, Venezuela to Trinidad and Brazil.

Brazil: Cepec, Ilheus, Bahia, 1966–1968, at light.

French Guyane: Sampson (1912:245).

Guiana: Cited in Wood & Bright (c1992:657).

Venezuela: Cheroni, Aragua, 23-V-1961, *Theobroma cacao*, J.L. Saunders; Valle de Cheroni, 3-VI-1964, *Theobroma cacao*, J.L. Saunders; Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 570, tree limbs, SLW; 9 km S Barrancas, Barinas, 5-XI-1969, 150 m, No. 103, *Cassia fistula* branches, SLW; 5 km W El Pino, Zulia, 20-X-1969, No. 138, tree limb, SLW; 13 km SW El Vigia, Merida, 22-X-1969, No. 76, *Inga*, SLW.

Hosts: *Alexa imperatricia*, *Brownia* sp., *Cassia fistula*, *Hymenostegia afzelii* Inga sp., *Sterculia* sp., *Theobroma cacao*.

Notes: The above treatment was based on 5 specimens from Brazil and 44 from Venezuela. Two specimens were compared by me directly to the holotype of *Bostrichus cristatus* Fabricius, *Xyleborus urichi* Sampson, *Xyleborus crenatus* Eggers, and *Dryocoetoides caracicolai* Hopkins.

Dryocoetoides obtusitruncatus (Schedl)

Plate LXXXIV

Dryocoetoides obtusitruncatus (Schedl), 1948:271 (*Xyleborus*). Lectotype ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien, de-

signed by Schedl 1979:176 (References in Wood & Bright c1992:658)

Diagnosis: This is the only known member of this genus having a complete circumdeclivital costa extending from the suture at the base of the elytral declivity to the suture at the apex of the elytra, the declivity appears obliquely truncate.

Female: Length 2.7–2.8 mm, 3.1 times as long as wide; color yellowish brown. Frons about as in *flavus* (Fabricius). Pronotum 1.1 times as long as wide; sides straight and parallel on basal two-thirds, very broadly rounded in front, anterior margin armed by 10–12 serrations; summit in front of middle, asperities small, numerous, disc smooth, shining, punctures moderately large. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; disc occupying basal 70 percent of elytral length, abruptly, obliquely truncate behind; disc smooth, shining glabrous, striae not impressed, punctures small, shallow, in rows (obscure on basal fourth); interstriae about five times as wide as striae, punctures rather numerous, confused, almost as large as those of striae. Declivity abruptly, obliquely truncate, a subacute circumdeclivital costa extending from suture at apex to suture at base; striae weakly sinuate, slightly impressed, punctures impressed, slightly larger than those on disc; interstriae tuberculate, tubercles confused, except uniseriate on 3, with 1 widest below middle of declivity length; declivital face convex, except near margins, summit on lower half; glabrous.

Distribution: Brazil to Paraguay.

Brazil: Nova Teutonia, Santa Catarina; Porto Uniao, 13-X-1998, Swedish Match, hexanol intercept trap, *Populus deltoides* stand, C.A.H. Flechtmann; Tres Lagoas, Mato Grosso, CPC, Horto Barra do Moeda, 10-II-1994, ethanol trap, *Eucalyptus grandis* stand, C.A.H. Flechtmann.

Paraguay: San Bernardino, 1909, K. Fiebrig.

Notes: The above treatment was based on 7 females from Paraguay and several from Mato Grosso and Santa Catarina in Brazil.

Dryocoetoides velutinus Wood

Plate LXXXIV

Dryocoetoides velutinus Wood, 1974:29. Holotype ♀; Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:659)

Diagnosis: Declivital striae, tuberculate interstriae, and elytral disc much as in *obtusitruncatus* (Schedl), except circumdeclivital costa absent except on lower fourth; declivity rugose-reticulate.

Male: Length 2.9 mm, 2.4 times as long as wide. Head deformed, a moderate impression on median half of frons; eyes greatly reduced in size. Pronotum 1.3 times as long as wide, subquadrate; slightly less than anterior half strongly, triangularly concave to anterior and anterolateral subcostate margins, median fifth of anterior margin protruding slightly cephalad, lateral areas

of posterior parts of concave area rounded; asperities obsolete, disc smooth, shining, punctured. Posterior face of protibia unarmed by tubercles. Elytra slightly shorter than pronotum; resembling female.

Female: Length 2.8–3.0 mm, 2.5 times as long as wide; color dark reddish brown. Frons about as in *flavus* (Fabricius). Pronotum 1.13 times as long as wide, sides almost straight and parallel on basal half, somewhat narrowly rounded in front, anterior margin armed by about 6 serrations; summit at or slightly behind middle, asperities rather small, close; disc smooth, shining, punctures minute. Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; disc occupying basal two-thirds of elytral length; striae not impressed, punctures very small, usually confused near base, in rows to middle of elytra then obsolete; interstriae almost smooth, shining on basal half becoming rugose-reticulate before base of declivity, punctures very small, mostly confused. Declivity steep, broadly convex, basal margin rounded; striae punctures visible at least on lower half; interstriae rugose-reticulate, armed by tubercles, tubercles uniseriate on basal half of 1 and 3, mostly confused elsewhere; ventrolateral costa subserrate from suture to level near base of declivity, not joining 8. Vestiture of interstitial hair from base to apex, of moderate length and abundance.

Distribution: Venezuela: 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 538, in pandanga, SLW.

Hosts: "Pandanga" (Balbino Rodriguez identification).

Biology: Boring in a broken branch.

Notes: The above treatment was based on the type series of 1 male and 21 females.

Dryocoetoides indolatus Wood

Plate LXXXII

Dryocoetoides indolatus Wood, 1974:31. Holotype ♀; Campamento Rio Grande 30 km E Palmar, Bolivar, Venezuela; USNM, Washington (References in Wood & Bright c1992:658)

Diagnosis: Distinguished from *velutinus* Wood by the larger size; by the distinct rows of striae punctures; and by the larger tubercles on declivital interstriae 9.

Female: Length 3.7–3.8 mm, 2.7 times as long as wide; color dark reddish brown. Frons similar to *flavus* (Fabricius). Pronotum 1.14 times as long as wide; almost subquadrate, sides feebly arcuate, anterior margin very broadly procurved, margin feebly, obscurely serrate; summit at middle, asperities rather small, numerous; disc smooth, shining, punctures small. Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; disc occupying basal half; striae not impressed, punctures very small, distinct, in rows; interstriae about six times as wide as striae, smooth, shining, punctures smaller than those of striae, numerous, confused. Declivity rugose-reticulate, very gradual on basal half, rather steep behind; striae 1–8 indicated by rows of punctures, punctures at least twice as large as those on disc, interstriae armed by moderately large, subacute tubercles, tubercles on

1–3 confused on basal half, mostly uniseriate laterally and near apex. Vestiture of fine hair, mostly glabrous on disc, rather abundant and moderately long on declivity.

Distribution: Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 578, *Parinari excelsa* in rain forest, SLW.

Hosts: *Parinari excelsa* (Balbino Rodriguez identification).

Notes: The above treatment was based on the type series of 2 females, the holotype, and 1 paratype.

Dryocoetoides insculptus Wood

Plate LXXXIII

Dryocoetoides insculptus Wood, 1974:30. Holotype ♀; Carton de Colombia forest 8 km S Colonia (near Buenaventura), Valle de Cauca, Colombia; USNM, Washington (References in Wood & Bright c1992:658)

Diagnosis: Distinguished from *indolatus* Wood by the larger size; by the replacement of a continuous ventrolateral costa on declivity by a row of separate tubercles; and by the very different elytral sculpture.

Female: Length 4.7–4.9 mm, 2.7 times as long as wide; color dark reddish brown. Frons more strongly convex than *flavus* (Fabricius), with granules widely distributed. Pronotum 1.15 times as long as wide, sides almost straight on basal two-thirds, anterior margin strongly procurved, weakly serrate; summit near middle, asperities small, numerous; disc smooth, shining, punctures very small. Elytra 1.6 times as long as wide; disc occupying slightly less than basal half; striae not impressed, punctures moderately coarse, deep; interstriae smooth, shining, about four times as wide as striae. Declivity rugose-reticulate, very gradual on basal half, steep behind; striae strongly impressed, punctures larger than on disc, obscurely indicated; interstriae convex, each about half as high as wide, each armed by a uniseriate row of about 8 smooth, moderately coarse tubercles, tubercles continued below but much smaller to obsolete by apex, confused on 1 below. Vestiture confined to declivity, mostly of uniseriate rows of interstitial hair; most setae slightly shorter than distance between rows.

Distribution: Colombia: Carton de Colombia forest 8 km S Colonia (near Buenaventura), Valle de Cauca, 9-VII-1970, 30 m, No. 605, *Humiristrum excelsum*, SLW.

Hosts: *Humiristrum excelsum* (Carton de Colombia identification).

Notes: The above treatment was based on the type series of 9 females from Colombia.

Dryocoetoides alter (Eggers)

Dryocoetoides alter (Eggers), 1931:22 (*Xyleborus*). Holotype ♀; Brazil; USNM, Washington (References in Wood & Bright c1992:656)

Diagnosis: Distinguished from *insculptus* Wood by the absence of rugose-reticulate areas on the elytral declivity; by the much less strongly impressed striae at the base of the declivity; and by the smaller size.

Male: Length 2.5 mm, 2.4 times as long as wide. Pronotum 1.2 times as long as wide; anterior two-fifths triangularly, strongly concave, apical angle on lower half of concavity acutely elevated, a median, pointed tubercle on crest of carina; middle third in lateral areas with weak asperities; disc smooth, shining, punctures rather small, moderately abundant. Elytra 1.2 times as long as wide, 1.0 times as long as pronotum; disc about as in female, except punctures slightly larger; declivity more gradual, resembling female but features poorly formed.

Female: Length 3.7 mm, 2.6 times as long as wide; color reddish brown. Frons about as in *flavus* (Fabricius). Pronotum 1.1 times as long as wide; sides on basal half feebly arcuate, rather strongly procurved in front, anterior margin armed in median area by 6 serrations; summit at middle, anterior slope closely, rather coarsely asperate, small tubercles at summit less than twice as wide (transversely) as longitudinal thickness; disc smooth, shining, punctures moderately large. Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; disc occupying two-thirds of elytral length; striae feebly impressed, punctures rather small, distinct; interstriae about four times as wide as striae, smooth, shining on basal two-thirds, irregular, somewhat reticulate near declivity, punctures smaller than those of striae, confused on 2 and 3, mostly uniseriate on 1 and 4. Declivity steep, convex; striae slightly impressed, punctures slightly larger than on disc; interstriae almost smooth to obscurely reticulate, armed by numerous subacutely pointed, tubercles of moderate size, tubercles confused except uniseriate on basal half of 1; ventrolateral crest acute, serrate, not joining 8. Vestiture of moderately abundant, confused hair from base to apex; most setae about equal in length to width of an interstriae.

Distribution: Brazil: Mat. No. 17, Rio Claro, Sao Paulo, III-1947, XII-1947 (apparently taken at light); Agudos Durafloa, Sao Paulo, 27-I-1987, ethanol trap in *Pinus c. ribacea* stand, C.A.H. Flechtmann, same, 17-IX-1985, *Pinus c. durenensis* stand, C.A.H. Flechtmann; Parana, Monte Alegre, 22-III-1996, ethanol trap in *Eucalyptus grandis* stand, C.A.H. Flechtmann; Telemanco Borba, Parana, KPC, ethanol trap, 7-II-1997, *Pinus taeda* stand, C.A.H. Flechtmann.

Notes: The above treatment was based on 1 male and 1 female; the female was compared to the holotype by me.

Dryocoetoides asperulus (Eggers)

Dryocoetoides asperulus (Eggers), 1931:21 (*Xyleborus*). Holotype ♀; Mexico: MNB, Berlin (Schedl 1979:28 gives NHMW, Wien); (Synonymy and references in Wood & Bright c1992:656)
Xyleborus imitator Schedl, 1976:75. Holotype ♀; Barueri, Sao Paulo, Brazil; NHMW, Wien

Diagnosis: Distinguished from *alter* (Eggers) by the impressed declivital striae 1–3, with punctures twice as

large as those of disc; and by the subacutely elevated ventrolateral crest of the declivity.

Female: Length 4.3 mm, about 2.7 times as long as wide (elytra spread, estimated); color reddish brown. Frons about as in *flavus* (Fabricius). Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal two-thirds, broadly rounded in front, anterior margin weakly armed by 8 obscure serrations; summit anterior to middle, asperities rather small, numerous, small crenulations at summit 3–8 times as wide (transversely) as thick (longitudinally); disc smooth, shining, punctures of moderate size; vestiture hairlike, mostly confined to sides. Elytra about 1.6 times as long as wide, about 1.5 times as long as pronotum; disc occupying basal two-thirds; striae not impressed except weakly near declivity, punctures small; interstriae about five times as wide as striae, punctures confused, almost as large as those of striae, uniseriate tubercles beginning well before base of declivity. Declivity steep, convex; striae feebly impressed, punctures about equal in size to those of disc; interstriae obscurely subreticulate, tubercles mostly small, confused except almost uniseriate on 3. Vestiture of interstitial hair from base to apex, some setae on declivity equal in length to twice width of an interstriae.

Distribution: “Mexico” (type of *asperulus*) to Costa Rica and Brazil.

Brazil: Barueri, Sao Paulo (type of *imitator*); Aracruz, Espirito Santo, 19-X-1988, No. 2232, 11-XII-1991, No. 3585; Agudos, Sao Paulo, 2-VIII-1994, Durafloa S.A., *Pinus caribea hondurensis* stand.

Notes: The above treatment was based on 1 female from Costa Rica that was compared by me to Schedl’s specimens and 1 from Brazil.

GENUS *THEOBORUS* HOPKINS

Theoborus Hopkins, 1915:57. Type-species: *Theoborus theobromae* Hopkins, original designation (References in Wood & Bright c1992: 660–662)

Diagnosis: Antennal club with 2 sutures visible on posterior face as in *Dryocoetoides*; distinguished from that genus by the flat, smooth posterior face of the protibia; and by the more finely faceted eyes.

Description: Body of female 1.7–3.0 mm, 2.3–2.8 times as long as wide; color brown to almost black. Male dwarfed, deformed, flightless. Description about as in *Dryocoetoides* except for antennal club and protibial characters.

Distribution: Wood & Bright (c1992:660–662) report eight species from Central and South America, 4 of which occur in South America, 1 was introduced into tropical Africa.

Biology: Insufficient information is available to distinguish the habits and behavior of this genus from *Dryocoetoides* and *Xyleborus*.

Key to the Species of *Theoborus*
(Modified from Wood 1982:770–772)

1. Elytral declivity strongly convex, its posterolateral margin rounded and devoid of crenulations; strial and interstitial punctures on disc small, shallow, confused or in definite rows; declivital interstitial punctures replaced by minute granules 2
- Elytral declivity very broadly convex to weakly impressed, its posterolateral margin subacutely elevated and carinate or crenulate from sutural apex to interstriae 7; strial punctures in definite rows easily distinguishable from interstitial punctures 4
- 2(1). Strial and interstitial punctures on disc in uniseriate rows; declivital interstriae 2 slightly impressed; anterior margin of pronotum armed by 2 serrations; Costa Rica; *Protium panamensis*; 1.7 mm *paurus* Wood
- Strial and interstitial punctures on disc confused; declivital interstriae 1–3 evenly convex; anterior margin of pronotum armed by 6 serrations 3
- 3(2). Smaller; punctures on pronotal disc smaller, shallow; elytral punctures larger, more distinctly granulate on declivity; Antilles Islands and Costa Rica to Colombia and Venezuela; 1.8–2.1 mm *theobromae* Hopkins
- Larger; punctures on pronotum disc larger, deeper; elytral punctures smaller, about half as large, very feebly granulate on declivity; Guatemala to Bolivia and Argentina; 2.3 mm *villosulus* (Blandford)
- 4(1). Elytral declivity broadly convex, its posterolateral margin unevenly costate, somewhat crenulate; interstriae four to six times as wide as striae, strial punctures very small, usually little if any larger than those of interstriae (except *molestulus*); color dark brown 5
- Elytral declivity moderately impressed at least on interstriae 2, its posterolateral margin a continuous costa; interstriae about three times as wide as striae, strial punctures moderately large, at least twice as large as those of interstriae; color yellowish to light reddish brown 9
- 5(4). Body more slender, at least 2.6 times as long as wide 6
- Body stouter, less than 2.3 times as long as wide 8
- 6(5). Declivital interstriae 2 impressed and unarmed on lower two-thirds, 1 and 3 slightly elevated, tubercles on 1 confused; Mexico (Campeche) to Panama; 2.3 mm *incultus* (Wood)
- Declivital interstriae 1–3 uniseriately, finely tuberculate, 2 not impressed, 1 and 3 not elevated 7
- 7(6). Strial punctures on disc very small, spaced within a row by three to four diameters of a puncture; declivity rather abrupt, steep, its surface somewhat shagreened, cusps on ventrolateral margin higher, those near suture coarse, declivital interstitial vestiture of long, fine hair two to three times longer than distance between rows, strial hair up to half as long; Costa Rica to Panama; 1.7–2.0 mm *pristis* Wood
- Strial punctures somewhat larger, spaced within a row by one to two diameters of a puncture, declivity more gradually, more broadly arched, shining, cusps on ventrolateral margin low, not particularly larger near suture; interstitial declivital vestiture stout, very slightly longer than distance between rows, strial hair fine, at least half as long as that of interstriae; Costa Rica; 1.8–2.0 mm *micarius* Wood
- 8(5). Interstitial punctures on disc confused, not replaced by granules; declivital vestiture more abundant, consisting of strial rows and confused interstitial hair; Panama to Venezuela (Barinas); 1.9–2.3 mm *crinitulus* (Wood)

- Interstitial punctures uniseriate, mostly replaced by small tubercles to base; elytral setae in uniseriate rows; Panama; 2.0–2.2 mm *molestulus* Wood
- 9(4). Smaller; elytral declivity shorter, steeper, occupying 30 percent of elytral length, more narrowly impressed particularly on lower half; interstitial setae on declivity very stout, short, as long as distance between rows or less; Africa (introduced), Antilles Islands, and Mexico (Veracruz) to Brazil; 2.3–2.5 mm *ricini* (Eggers)
- Larger; elytral declivity more gradual, occupying 40 percent of elytra length, more broadly impressed on lower half; interstitial setae on declivity slender, pointed, about one and one-half times as long as distance between rows; Antilles Islands and Mexico (Chiapas) to Costa Rica, Colombia and Brazil; 2.5–2.9 mm *coartatus* (Sampson)

Theoborus paurus Wood, n. sp.

Theoborus paurus Wood: Holotype ♀; Est. Biol. La Selva, Heredia, Costa Rica; USNM, Washington, designated below

Diagnosis: Remotely allied *T. incultus* Schedl, but distinguished by the smaller, stouter body form; by the remotely similar, simple declivity; and by other characters described below.

Female: Length 1.7 mm, 2.1 times as long as wide; color medium reddish brown. Frons convex, reticulate, punctures small, moderately abundant; vestiture sparse, hairlike, inconspicuous. Pronotum 1.0 times as long as wide, anterior margin slightly produced at median line and armed by 2 or 3 basally contiguous, rather coarse serrations; summit at middle of pronotum length, anterior slope asperate as in *incultus* (Wood); basal and lateral areas reticulate, punctures small, moderately abundant; vestiture hairlike, moderately abundant, rather long. Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; striae not impressed; interstriae three to four times as wide as striae, surface almost smooth, shining, punctures minute (one-third as large as those of striae), in uniseriate rows. Declivity confined to posterior third of elytra length, steep, broadly convex; apical margin rounded (not armed by a carina or row of denticles); lower two-thirds shallowly impressed between left and right interstriae 3, lower third of interstriae 1 slightly elevated; interstriae 1 armed by a row of about ten small denticles, 2 with a staggered row of very minute, obscure granules, 3 with row of about six small, pointed tubercles (larger than those on 1). Vestiture of minute strial hairlike setae on disc and declivity, and erect interstitial setae at least on sides and declivity, of moderate to short length.

Distribution: Costa Rica.

Type material: The female holotype was taken at Est. Biol. La Selva, Heredia, Costa Rica, ERO/11/a/042m 12-VI-1995, *Protium panamensis*. The holotype is in the U.S. National Museum, Washington.

Theoborus theobromae Hopkins

Plate LXXXIII

Theoborus theobromae Hopkins, 1915:57. Holotype ♀; Dominicana, West Indies; USNM, Washington (Synonymy and references in Wood & Bright c1992:661)

Xyleborus pseudococcotrypes Eggers, 1941:105. Holotype ♀; St. Jean du Maroni, French Guyane; MNHN, Paris
Xyleborus hirtellus Schedl, 1948:271. Lectotype ♀; St. Vincent, Trinidad; NHMW, Wien, designated by Schedl 1979:118

Diagnosis: Distinguished by the strongly convex elytral declivity, its posterolateral margin rounded and devoid of crenulations; by the small punctures on the pronotum disc; and by the small size.

Male: Length 1.3 mm, 2.0 times as long as wide; color pale yellow. Head deformed, frons with a median sulcus; eyes of greatly reduced size. Pronotum 1.2 times as long as wide; anterior half deeply, broadly concave, anterior margin subacute, with a small, acute, median tubercle; lateral margins rounded, surface reticulate, devoid of tubercles and asperities on sides and concave area; disc obscurely reticulate, punctures small, poorly formed. Elytra 1.1 times as long as wide, 0.90 times as long as pronotum sculpture resembling female but all features poorly formed.

Female: Length 1.8–2.1 mm, 2.4 times as long as wide; color dark brown. Frons moderately convex and rugose-reticulate above, feebly convex below, reticulate, punctures sparse, small; vestiture of fine, short, sparse hair. Pronotum 1.0 times as long as wide; summit at middle of pronotum length; anterior slope closely, rather coarsely asperate; disc weakly reticulate, punctures very small, not close. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; disc occupying slightly more than basal half of elytral length, surface smooth, shining, punctures small, confused. Declivity broadly convex, steep; striae 1–3 each indicated by a row of small, shallow punctures; interstriae smooth, shining, each with a uniseriate row of small tubercles. Vestiture of fine, moderately long strial and interstitial hair, rather abundant on posterior half, usually sparse to absent on basal half.

Distribution: Mexico (Veracruz) and Antillies Islands to Colombia, Venezuela, and French Guyane.

Colombia: El Pleceros Rosas, Valle de Cauca, 28-IV-1959, cafe, J.L. Arboleda; El Vergal, La Palma, Cundinamarca, 24-IV-1959, cafe, A. Diaz; El Pensil, Palermo, Huila, 30-IV-1959, *Theobroma cacao*, B. Herrera; Piemonte, Palermo, Huila, 29-IV-1959, cacao, B. Herrera.

French Guyane: Cayenne; St. Jean du Maroni.

Venezuela: Campamento Rio Grande 30 km E Palmar, Bolivar, 12-VI-1970, 200 m, No. 549, *Alexa imperatrix*, SLW, same No. 527 *Cecropia* branches; Rancho Grande, Pittier N.P., Aragua, 9-IV-1970, 1100 m, No. 432, Guttiferae, No. 470 *Piper*; Merida, Merida, 22-IX-1969, 1700 m, No. 16, *Ficus*, SLW; 9 km S Brancas, Barinas, 2-XII-1969, 150 m, No. 152, *Pithecolobium saman*, SLW.

Hosts: *Alexa imperatrix*, *Cecropia*, *Coffea*, *Erythrina costaricensis*, *Ficus*, *Ochroma*, *Piper*, *Theobroma cacao*.

Biology: Breeds in small stems.

Notes: The above treatment was based on 37 specimens from Central America, 12 from the Antilles Islands, 5 from Colombia, 2 from French Guyane, and 67 from Venezuela. One of these was compared to the holotype of *Theoborus theobromae* Hopkins, 2 to the holotype of *Xyleborus pseudococcotrypes* Eggers, and 1 to the lectotype of *Xyleborus hirtellus* Schedl.

Theoborus villosulus (Blandford)

Plate LXXXIII

Theoborus villosulus (Blandford), 1898:204 (*Xyleborus*). Holotype ♀; Rio Naranjo, San Marcos, Guatemala; BMNH, London (Synonymy and references in Wood & Bright c1992:661–662)

Xyleborus coccotrypoides Eggers, 1943:388. Holotype ♀; Cochabamba, Bolivia; MNHN, Paris

Xyleborus villosus Schedl, 1948:270. Syntypes ♀ ♀; Nova Teutonia, Santa Catarina, Brazil; NHMW, Wien

Diagnosis: Distinguished from *theobromae* Hopkins by the larger size; by the larger, deeper punctures on the pronotum disc; by the smaller elytral punctures; and by the smaller, sometimes obsolete interstitial granules on the declivity.

Female: Length 2.3 mm, 2.4 times as long as wide; color brown. Frons and pronotum as in *theobromae* except pronotum disc more strongly reticulate, punctures slightly larger, deeper. Elytra with punctures on disc smaller than *theobromae*, on declivity striae punctures less distinct, interstitial granules mostly smaller, partly obsolete.

Distribution: Guatemala to Bolivia and Argentina.

Argentina: Cited in Wood & Bright (c1992:662).

Bolivia: Cochabamba, Woytkowski (Eggers 1943:388).

Brazil: Telemaco Borba, Parana, 31-XII-1999, 3-III-2000, 10-X-2000, Klabin Papel e Cellulose, sulcatol trap, ethanol trap, C.A.H. Flechtmann; Nova Teutonia, Santa Catarina (Schedl 1948:388); Duraflora, Agudos, Sao Paulo, 19-IV-1988, ethanol trap, *Pinus c. caribica* stand, C.A.H. Flechtmann.

French Guyane: Cayenne (Wood & Bright c1992:662).

Peru: Cited in Wood & Bright c1992:662.

Venezuela: Rancho Grande, Aragua, 9-IV-1970, 1100 m, No. 404, tree branch, SLW.

Hosts: "Anonillo," *Inga* sp., *Pinus elliotti*, *Theobroma cacao* (Wood & Bright c1992:661–662).

Biology: Taken from broken tree branches.

Notes: The above treatment was based on 2 specimens from Guatemala (including the type of *villosulus*

Blandford), 1 from Venezuela, and on the types of *coccotrypoides* (Eggers) and *villosus* (Schedl).

Theoborus crinitulus (Wood), n. comb.

Plate LXXXVII

Theoborus crinitulus (Wood), 1974:34 (*Xyleborus*). Holotype ♀; 40 km SE Socopo, Barinas, Venezuela; USNM, Washington (References in Wood & Bright c1992:721)

Diagnosis: Distinguished from *molestulus* Wood by the uniseriate interstitial punctures on the disc that have been replaced by small tubercles to the base; and by the uniseriate interstitial setae.

Female: Length 1.9–2.3 mm, 2.3 times as long as wide; color dark reddish brown. Frons broadly convex (weakly on lower half), surface weakly reticulate, small sparse punctures mostly replaced on lower half by small, rounded granules; a very weak median elevation on upper half. Pronotum 1.0 times as long as wide; sides weakly arcuate on posterior two-thirds, broadly rounded in front; anterior margin irregularly armed by about 4 low serrations; summit near middle; anterior slope armed by numerous rather coarse asperities; disc smooth, shining, punctures moderately abundant, small. Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; disc occupying about half of elytra length; striae 1 weakly, others not impressed, punctures small, distinct, uniseriate; interstriae about four times as wide as striae, smooth, shining, with some irregular surface lines, punctures half as large as those of striae, confused. Declivity steep, very broadly convex, posterior profile (dorsal aspect) obtusely subangulate; striae not impressed, punctures more strongly impressed, slightly larger than on disc; interstriae two to three times as wide as striae, smooth, shining, each armed by a row of about eight to ten pointed tubercles of moderate size, each about as high as basal width of a tubercle; interstriae 1 on lower fourth modestly protuberant before apex; ventrolateral margin serrate and subacutely elevated from suture to near base of declivity, not joining 8. Vestiture largely confined to sides and declivity, more abundant and slightly longer on declivity.

Distribution: Africa (introduced) and Panama to Venezuela.

Venezuela: 40 km SE Socopo, Barinas, 25-I-1970, 150 m, No. 280, *Hirtella triandra*, SLW.

Notes: The above treatment was based on the type series of 17 specimens from Venezuela and 3 from Panama.

Theoborus ricini (Eggers)

Plate LXXXVII

Theoborus ricini (Eggers), 1932:298 (*Xyleborus*). Holotype ♀; Stanleyville, Congo; USNM, Washington (Synonymy and references in Wood & Bright c1992:661)

Xyleborus solitariceps Schedl, 1954:45. Lectotype ♀; Rondon, Parana, Brazil; NHMW, Wien, designated by Schedl 1979:232

Diagnosis: Distinguished from *coartatus* (Sampson) by the smaller size; by the shorter, steeper elytral declivity; by the more narrowly impressed lower declivity; and by the shorter, stouter setae on the declivity.

Female: Length 2.3–2.5 mm, 2.5 times as long as wide; color yellowish brown to dark reddish brown. Frons broadly convex, almost smooth, shining between coarse punctures on upper half and rounded granules (tubercles) on lower half; vestiture of moderately abundant, fine, long hair on lower half. Pronotum 1.1 times as long as wide; sides straight and parallel on basal two-thirds, broadly rounded in front; anterior margin armed by about 6 coarse serrations in median area; summit at middle, anterior slope rather coarsely, closely asperate, disc mostly reticulate, punctures moderately large, rather close. Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; striae not impressed at base, feebly impressed toward base of declivity, punctures rather small, deep; interstriae smooth, shining, two to three times as wide as striae, punctures slightly more than half as wide as those of striae, punctures uniseriate on 1 and 3, confused on 2 and 4. Declivity occupying slightly more than posterior third of elytral length, steep; striae slightly impressed, punctures slightly larger than on disc; interstriae 1 slightly impressed, 2 and 3 weakly convex, each armed by a row of moderately coarse tubercles; ventrolateral margin subacutely elevated, serrate. Vestiture hairlike, moderately abundant to base, rather short.

Distribution: Africa (introduced), Mexico (Veracruz), and Antilles Islands to Colombia and Brazil.

Brazil: Cepec, Ilheus, Bahia, 1966–1968, at light.

Colombia: Libano, Tolima, 2-VI-1959, *Theobroma cacao*, E. Piedrahita; Partachuelo, Rio Negro, Santander Sur, 26-VI-1959, cacao verde, E. Rangel.

Venezuela: Finca Monasterios, Cacaugua, Miranda, 1971, *Theobroma cacao*, J.L. Saunders.

Hosts: *Albizzia gummifera*, *Aptandra zenkeri*, *Citrus aurantifolia*, *Dioclea megacarpa*, *Hevea brasiliensis*, *Maesa rufescens*, *Ricinus communis*, *Swietenia* sp., *Terminalia* sp., *Tetrapleura tetraptera*, *Theobroma cacao* (Schedl 1962:289 adds other African hosts).

Biology: Boring in large limbs and stumps.

Notes: The above treatment was based on 3 specimens from Africa, 2 from Jamaica, 16 from Central America, 1 from Brazil, 4 from Colombia, and 1 from Venezuela, all females. One female was compared by me directly to the holotype of *Xyleborus ricini* Eggers and also to the lectotype of *Xyleborus solitariceps* Schedl.

Theoborus coartatus (Sampson)

Plate LXXXVI

Theoborus coartatus (Sampson), 1921:32 (*Xyleborus*). Holotype ♀; Trinidad; BMNH, London (Synonymy and references in Wood & Bright c1992:661)

Xyleborus artecuneolus Schedl, 1939:14. Holotype ♀; Trinidad; BMNH, London

Diagnosis: Distinguished from *ricini* (Eggers) by the larger size; by the more gradual slope of the elytral declivity; by the more broadly impressed lower declivity; and by the more slender, longer declivital setae.

Male: Length 2.3 mm, 2.5 times as long as wide; color yellowish brown; head as in *theobromae* Hopkins; pronotum as long as wide, anterior half deeply concave on median half, anterior margin obtusely produced, subacutely elevated on less than median half (not exactly forming a tubercle on obtuse median line); lateral margins of concave area broadly rounded, surface obscurely reticulate, asperities absent, punctures small on anterior half, moderately large on disc.

Female: Length 2.5–2.9 mm, 2.6 times as long as wide; color reddish brown. Frons and pronotum very similar to female *ricini*. Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; disc occupying 60 percent of elytra length; striae not impressed, punctures moderately deep, rather small, interstriae about three times as wide as striae, smooth, shining, punctures half as large as those of striae, mostly uniseriate, moderately confused on 2, feebly confused on 3 and 4. Declivity moderately steep, less than in *ricini*; interstriae 1 and lower half of 2 distinctly impressed, tubercles on 1–3 very small to obsolete below. Vestiture of fine hair; distinctly longer than in *ricini*, ventrolateral margin less strongly elevated, more finely serrate.

Distribution: Africa (introduced), Mexico (Chiapas) and Antilles Islands to Brazil.

Brazil: Cepec, Ilheus, Bahia, 1966–1968, at light; Minas [Geraiis?]; Itiquiera, MS, 28-IX-1992, *Hevea brasiliensis* clone PB235, branch, O. Dall'Oglio.

Colombia: Palmira, Valle de Cauca, I-1947, 3-245, B. Losada; Hidaga Jamaica, Nilo, Cunadin, cacao; Ibaque, Tolima, No. 14, *Theobroma cacao*, L.M. Murillo.

Hosts: *Mimosa* sp., *Theobroma cacao*.

Biology: Boring in large limbs and stumps. It is a minor pest of cacao.

Notes: The above treatment was based on 4 specimens from Mexico (Chiapas), 13 from Central America, 2 from Brazil, and 10 from Colombia. One specimen was compared to the holotype of *Xyleborus coartatus* Sampson and also to the lectotype of *Xyleborus artecuneolus* Schedl.

GENUS *COPTOBORUS* HOPKINS

Coptoborus Hopkins, 1915:53. Type-species: *Coptoborus emarginatus* Hopkins = *Xyleborus vespatorius* Schedl, original designation (Synonymy and references in Wood & Bright c1992:662–665)

Streptocranus Schedl, 1939:52. Type-species: *Streptocranus mirabilis* Schedl, monobasic (Synonymy and references in Wood & Bright c1992:662)

Diagnosis: Distinguished from *Theoborus* by the more slender body form, with the elytra attenuate or acuminate on the posterior third, narrowly rounded behind, the suture often emarginate at its apex; one or more declivital interstriae armed by small denticles.

Description: Length 1.5–5.0 mm, slender, at least 2.6 times as long as wide; color yellowish to reddish brown. Posterior face of antennal club marked by two sutures, suture 2 obscure in some species, club face concave only distad from comparatively large segment 2. Protibia armed on lateral margin by 6 or 7 socketed denticles, metatibia with 6–9 socketed denticles; anterior coxae contiguous. Elytra attenuate or acuminate behind; one or more declivital interstriae armed by small denticles.

Distribution: Wood & Bright (c1992:662–665) report 27 species from Africa, southeastern Asia, and tropical America. Of these, 10 occur in South America.

Biology: All of the South American species are small and breed in small stems. Except for their xylomycetophagous habit, their habits have not been studied in detail.

Key to the Species of *Coptoborus*
(Females only)

- 1. Elytral declivity with interstriae 2 unarmed (at least on lower half), 3 armed by denticles and sometimes elevated; declivity occupying at least 40 percent of elytra length 2
- Elytral declivity with interstriae 1–3 about equally sculptured, with or without tubercles 9
- 2(1). Lower elytral declivity on posterior half weakly to strongly sulcate, interstriae 3 moderately to strongly elevated 3
- Declivity convex to weakly flattened on lower half; declivity occupying about 33 percent of elytral length; small species 8a
- 3(2). Lower declivity moderately to very strongly sulcate, interstriae 3 strongly elevated 4a
- Lower declivity weakly sulcate, interstriae 3 weakly elevated 5
- 4a(3). Elytral declivity entirely devoid of tubercles on interstriae 1–3 and glabrous; slightly larger species; Brazil (Mato Grosso); 2.6 mm *nudulus* Wood
- Declivital interstriae 1 or 3, or both, armed by small tubercles, declivital setae present; slightly smaller species 4b
- 4b(4a). Declivital interstriae 1 and 2 unarmed by tubercles except at extreme base, interstriae 3 subacutely elevated, armed by three to five denticles, apical margin strongly, acutely elevated and obtusely emarginate; Mexico (Veracruz) to Argentina; 2.3–2.8 mm *vespatorius* (Schedl)
- Interstriae 1 armed by a row of small tubercles on basal two-thirds, 2 with a similar row on basal half or less, elevation on 3 limited to lower third, moderately strong near apex, crest of 3 armed by a row of small tubercles of approximately equal size; interstitial setae rather short, stout; attracted to light; Suriname; 2.4 mm *schulzi* Wood
- 5(3). Apex of elytral declivity more broadly rounded behind (as seen from dorsal aspect; surface of declivity dull; body less slender; Suriname; female 2.1–2.2 mm, male 2.0 mm *spicatus* Wood
- Apex of declivity as seen from dorsal aspect more narrowly rounded; declivital surfaces more smooth, shining; body more slender 6
- 6(5). Apical margin at declivital suture more acutely elevated; setae on declivity much longer; pronotum rather strongly reticulate, punctures moderately large; color very dark brown; Costa Rica to Panama; 2.3 mm *exilis* (Schedl)
- Apical margin at sutural emargination less acutely elevated; setae on declivity rather short; pronotum disc weakly reticulate, punctures minute to obsolete 7
- 7(6). Elytral declivity distinctly steeper; body form less slender; profile of posterior margin more broadly rounded; declivital setae much more slender; color reddish brown; Brazil (Santa Catarina); 1.8 mm *subtilis* (Schedl)

- Elytral declivity more gradual, interstriae 3 often (not always) with a tubercle on lower half distinctly larger; body form more slender; profile of posterior margin of declivity narrower; most declivital setae distinctly stouter; color usually yellowish brown; Mexico (SLP, Veracruz) to Panama and Venezuela to Brazil; 1.8–2.2 mm *pseudotenius* (Schedl)
- 8a(2). Elytral declivity more narrowly, more evenly convex, interstriae 1 and 3 each with about four to six small denticles, ventrolateral margin armed by a row of three to four small denticles from margin of emargination to level of interstriae 3; on disc striae and interstitial punctures minute; Panama to Venezuela and Peru; 1.6–1.7 mm *cuneatus* (Eichhoff)
- Elytral declivity more broadly, weakly convex, interstriae 1 and 3 each with about four to six small denticles, ventrolateral margin without any denticles; striae punctures on disc distinctly larger; Brazil; 1.6–1.9 mm 8b
- 8b(8a). Body 2.6 times as long as wide; anterior margin of pronotum armed by eight moderately coarse serrations; declivity more narrowly convex, not as steep; declivital interstriae 1 with about six to ten denticles closely spaced; Brazil (Mato Grosso); 1.75 mm *solitariformis* (Schedl)
- Body 3.0 times as long as wide; anterior margin of pronotum without definite serrations; declivity steeper; more broadly convex; declivital interstriae 1 with about four tubercles, more widely spaced; Panama to Suriname and Brazil; 1.6–1.9 mm *catulus* (Blandford)
- 9(1). Declivital interstriae 8 or 9 not elevated, without a distinct crest 10
- Declivital interstriae 9 slightly elevated and shining, often with a distinct crest 13
- 10(9). Pronotum disc smooth, shining, anterior margin unarmed by serrations; body smaller, more slender; declivital apex at suture armed by a coarse, blunt cusp, a row of pointed tubercles of decreasing size continuing toward interstriae 7; body more slender; Brazil (Mato Grosso); 1.7–1.8 mm *neosphenos* (Schedl)
- Pronotum disc reticulate, anterior margin armed by 2–4 serrations; body larger, stouter, darker; tubercles on margin of declivity small 11
- 11(10). Elytral declivity smooth, shining; ventrolateral margin of declivity more strongly elevated (with crest subserrate) from suture to interstriae 3, tubercles on 3 distinctly larger, those on 1 and 2 slightly larger; interstitial setae longer, more widely distributed; body form slender, 2.8 times as long as wide; Brazil (Guanabara); 2.2 mm *gentilis* (Schedl)
- Elytral declivity reticulate, dull; ventrolateral margin of declivity less strongly elevated, tubercles on 1–3 smaller; body form less slender, 2.6 times as long as wide 12
- 12(11). Punctures on declivital striae 1 and 2 larger, distinctly impressed in rows to apex, interstriae 1–3 with a few small tubercles; Puerto Rico; 2.3–2.4 mm *puertoricensis* Bright
- Punctures on declivital striae 1 and 2 smaller, in rows on basal third, confused below, interstriae 1–3 with tubercles almost entirely obsolete; Puerto Rico; 2.2 mm *bellus* Bright
- 13(9). Elytra 1.5–1.6 times as long as wide, posterior 40 percent tapered to apex, apex with two or more tubercles or cusps on lateral or dorsal margin; declivital interstriae 4 with a row of small tubercles; less slender species, 2.5–2.8 times as long as wide 14
- Elytra 2.8–3.2 times as long as wide, posterior 60 percent of elytra length strongly tapered to apex, apex curved slightly dorsad and not armed by cusps or tubercles; declivital interstriae 4 unarmed by tubercles; very slender species 18
- 14(13). Elytral apex subacute, its dorsal profile a continuation of profile of declivity at suture; body distinctly more slender 15

- Elytral apex distinctly produced caudad and somewhat dorsad, not exactly in line with profile of declivital suture; body distinctly stouter 16
- 15(14). Elytral apex with margin subacute, not armed by cusps or tubercles; tubercles on declivity smaller on median half, mostly obsolete in lateral areas; Costa Rica; 2.0 mm *exutus* Wood
- Elytral apex formed into a moderately large cusp, with a row of four or more tubercles continuing from cusp to interstriae 3; interstitial tubercles on declivity in rows, slightly larger and more extensively distributed; Costa Rica and Panama to Colombia, Venezuela and Brazil (Bahia); 1.8–2.2 mm *tolimanus* (Eggers)
- 16(14). Slightly smaller species, more slender, 2.8 times as long as wide; weakly raised elytral apex at suture without any tubercles on weak attenuate, raised margin; Brazil (Mato Grosso); 1.8 mm *inornatus* Wood
- Slightly larger, less slender species 2.5 times as long as wide; weakly raised attenuate apex of elytra at suture armed by several small tubercles 17
- 17(16). Apex of elytra moderately attenuate, bearing on dorsal and lateral surfaces 6–8 small, confused tubercles; declivital interstriae armed on about 1–5 by rows of regularly spaced, small, pointed tubercles; anterior margin of pronotum armed by 4 weak serrations; Paraguay; 2.2–2.4 mm *carumbensis* Wood
- Apex of elytra strongly attenuate, bearing on dorsal and lateral surfaces many very small, confused tubercles; declivital interstriae with rows of minute tubercles on 1–4; Brazil (Mato Grosso); 2.0 mm *attenuatus* Wood
- 18(13). Strial and interstitial punctures shallow, obscure, obsolete on basal fourth; elytra tapered on posterior 50 percent; Brazil (Espirito Santo); 1.8 mm *cracens* Wood
- Strial and interstitial punctures clearly marked on disc and extend to base; elytra tapered on posterior 60 percent of elytra length; Brazil (Espirito Santo); 2.2–2.5 mm *gracilens* Wood

Coptoborus vespatorius (Schedl)

Plate XCI

Coptoborus vespatorius Schedl, 1931:342 (*Xyleborus*). Holotype ♀; San Ignacio, Argentina; NHMW, Wien (Synonymy and references in Wood & Bright c1992:665)

Coptoborus emarginatus Hopkins, 1915:53. Holotype ♀; Livingston, Guatemala; USNM, Washington, preoccupied while in *Xyleborus*

Xyleborus corniculatus Schedl, 1948:275. Holotype ♀; Santa Catarina, Brazil; NHMW, Wien

Xyleborus corniculatulus Schedl, 1948:275. Holotype ♀; Trinidad; NHMW, Wien

Diagnosis: Distinguished by having declivital interstriae 1 and 2 unarmed except at extreme base; and by having the declivity strongly sulcate, interstriae 3 strongly elevated and armed by three to five denticles on the lateral margin.

Female: Length 2.3–2.8 mm, 3.4 times as long as wide; color reddish brown. Frons moderately convex, surface reticulate, punctures rather sparse; vestiture sparse, hairlike, mostly on epistomal margin. Pronotum 1.3 times as long as wide; summit well anterior to middle of pronotum length, anterior slope rather coarsely asperate, serrations on anterior margin usually small, indefinite; disc almost smooth, shining, very obscurely reticulate,

punctures small, widely spaced; glabrous except for sparse hair near anterior and lateral margins. Elytra 2.1 times as long as wide, 1.6 times as long as pronotum; disc occupying basal two-thirds of elytra length; striae not impressed, punctures small, uniseriate; interstriae almost smooth, shining, four to five times as wide as striae, punctures half as large as those of striae, uniseriate. Declivity gradual, broadly, rather deeply sulcate, lateral margins subacutely elevated, its crest armed by 3–5 denticles, about 2 of them moderately large, others much smaller; posterior profile obtusely emarginate on median third of elytra width; punctures on striae 1 and 2 clearly impressed to near apex, in rows, larger than on disc, interstitial punctures minute, obscure to obsolete. Mostly glabrous; sparse, interstitial, hairlike setae on declivity and on sides (often to base).

Distribution: Mexico (Veracruz) and Trinidad to Argentina.

Argentina: San Ignacio.

Brazil: Cepec, Ilheus, Bahia, 1966–1968, at light; Anacru, Espirito Santo, No. 7394, at light; Parque Esala, Piracicaba, Sao Paulo, 2-IV-1987, *Mangifera indica*, C.A.H. Flechtmann; Agudos, Duraflora, V-1984, ethanol trap in *Pinus* stand, Flechtmann.

Colombia: Arauquíl, San Andern, VII-1935, No. X457, M. Murillo; La Sofia, Valle de Cauca, 22-VIII-1955, cacao, M. Benevides; Punto Tejada, Valle de Cauca, 22-VIII-1955, cacao, No. 6886, M. Benevides; Palmira, Valle de Cauca, 3-III-1956, cacao, C. Carmona; Andolucia, V-1943, ramas, B. Lasada.

Venezuela: Rancho Grande, Aragua, 9-IV-1970, tree limb, SLW; Finca Monasterios, Cagagua, Miranda, 1971, *Theobroma cacao*, J.L. Saunders.

Hosts: *Theobroma cacao*, "tree limbs," "branches."

Biology: Boring in wood of limbs and stumps.

Notes: The above treatment was based on 3 specimens from Trinidad, 6 from Costa Rica, 3 from Brazil, 10 from Colombia, and 13 from Venezuela. Two females were compared directly by me to the female holotype of *Coptoborus emarginatus* Hopkins, *Xyleborus corniculatus* Schedl, *X. corniculatulus* Schedl, and *X. vespatorius* Schedl.

Coptoborus nudulus Wood, n. sp.

Coptoborus nudulus Wood: Holotype ♀; Sao Nicolau Farm, Cotriguacu, Mato Grosso, Brazil; ZMUSP, Sao Paulo, designated below

Diagnosis: Distinguished from *spicatus* Wood and *exilis* Wood by the slightly larger body size; by the absence of tubercles on declivital interstriae 1 and 3; and by the absence of elytral setae (one specimen with one to three minute tubercles on 1 and 3).

Female: Length 2.6 mm, 2.6 times as long as wide; color dark reddish brown. Frons moderately convex eye to eye from vertex to slightly above epistoma; surface above upper level of eyes minutely granulate, lower frons more finely subgranulate; sparse setae of moderate length on lower half, epistomal brush of sparse setae. Pronotum 1.1 times as long as wide; widest on middle third of pronotum length, sides feebly arcuate and subparallel on basal two-thirds; narrowly rounded in front; anterior slope steep; asperities rather coarse, close, confused; posterior areas and areas between asperities strongly reticulate, punctures very small, obscure, moderately numerous; glabrous except for a few short setae on asperate area. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; disc occupying 60 percent of elytra length; disc almost smooth, shining; striae not impressed, punctures very small, shallow; interstriae four to five times as wide as striae, almost smooth, mostly shining, punctures mostly uniseriate, about one-third as large as those of striae. Declivity rather gradual, somewhat broadly, shallowly bisulcate; sutural interstriae weakly elevated from base to near apex; interstriae 2 wider than 1 or 3, shallowly impressed from base to near apex; 3 weakly elevated, about as high as 1 on basal half, slightly lower below; 1 and 3 with zero to three very minute tubercles present; apical margin weakly elevated from suture to apex of interstriae 3 and armed by three to four weak serrations; punctures on striae 1 and 2 almost entirely obsolete. Glabrous.

Distribution: Brazil (Mato Grosso).

Type material: The female holotype and 1 female paratype were taken at Sao Nicolau farm, Cotriguacu, Mato Grosso, Brazil, VI-2002, ethanol trap in Amazon rain forest, O. Peres Filho. The holotype is in the Museum de Zoologie, Universidade de Sao Paulo, Sao Paulo. The paratype is in the U.S. National Museum, Washington.

Coptoborus schulzi Wood, n. sp.

Coptoborus schulzi Wood: Holotype ♀; Camp 8, Joden savanne, Suriname; USNM, Washington, designated below

Diagnosis: Distinguished from *vespatorius* Schedl by having the base of declivital interstriae 1 armed by a row of small tubercles; by the elevation of interstriae 3 limited to the lower third of the declivity, its crest armed by a row of small tubercles of equal size.

Female: Length 2.4 mm, 2.6 times as long as wide; color yellowish brown except reddish brown on declivity. Frons as in *vespatorius*. Pronotum 1.1 times as long as wide; resembling *vespatorius* except indefinite summit near middle, asperities smaller, more numerous, extending to a point slightly behind middle; glabrous, except sparse hair on anterior and lateral margins. Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; disc occupying slightly more than basal half of elytra length; striae not impressed, punctures small, distinct, in rows; interstriae about four times as wide as striae, smooth, shining, except with impressed irregular lines, punctures two-thirds as large as those of striae, confused. Declivity moderately steep; posterior profile shallowly, obtusely emarginate on less than median third; shallowly sulcate on lower half; striae 1 distinct, punctures in rows, 2 obscure, obsolete below; interstriae 1 and 2 each with a row of fine tubercles almost to apex, 3 on lower half moderately, obtusely elevated, crest with small confused tubercles. Vestiture mostly confined to declivity, consisting of rows of fine, short striae hair and stout interstitial scales, each scale about six to eight times as long as wide; all setae hairlike to base near lateral margins.

Distribution: Suriname.

Type material: The female holotype was taken at Joden savanne, Suriname, Camp 8, No. 55, light trap, Schulz. The holotype is in the U.S. National Museum, Washington.

Coptoborus spicatus Wood, n. sp.

Plate XC

Coptoborus spicatus Wood: Holotype ♀; Docsbury, Suriname; USNM, Washington, designated below

Diagnosis: Distinguished by declivital interstriae 2 being unarmed; profile of apex of elytral declivity more broadly rounded (not emarginate); and by the dull, subreticulate surface of the declivity.

Male: Length 2.0–2.1 mm, 2.6 times as long as wide; color yellowish brown. Head with frons as in female except shallowly sulcate in median area. Pronotum 1.3 times as long as wide; anterior 40 percent rather broadly,

deeply concave, anterior margin subacutely costate, a median obtuse point at median line, lateral obtuse points at ends of anterior costa, lateral margins above broadly rounded; surface of concave area reticulate, with small, confused punctures; disc reticulate, rather coarsely punctured; glabrous except for sparse hair near lateral margins.

Female: Length 2.1–2.2 mm, 2.7 times as long as wide; color yellowish brown. Frons as in *vespatorius* (Schedl). Pronotum 1.1 times as long as wide; summit at middle, asperities on anterior slope broad, coarse, profile of anterior margin obtusely subangulate, armed by 2 median serrations on margin and 4 submarginal serrations; disc reticulate, punctures minute; sparse hair on sides and anterior margin. Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; disc occupying slightly more than basal half; striae not impressed, punctures small, shallow, in rows; interstriae about three times as wide as striae, shining, surface not entirely smooth. Declivity moderately steep, shallowly bisulcate; punctures of striae 1 and 2 impressed, twice as large as those of disc, interstriae dull, subreticulate, 2 shallowly impressed, 1 and 2 weakly convex on basal half, 2 more strongly below, 1 and 2 with sparse tubercles above; apical margin distinctly elevated and serrate from suture to junction with 3, a few minute tubercles in lateral areas. Vestiture hairlike, short, sparse on lower declivity, longer on sides to base.

Distribution: Suriname.

Type material: The female holotype, male allotype, and 1 male and 9 female paratypes were taken at Docsbury, Suriname, 1932, LP199, LD199. The holotype, allotype, and paratypes are in the U.S. National Museum, Washington. The holotype is mounted in the upright (dorsal view) of 2 females mounted on 1 pin. The allotype is mounted with a female on the same pin.
